ROYAL ACADEMIES OF BERLIN AND OF NAPLES; OF THE AMERICAN SOCIETIES OF PHILADELPHIA
AND OF BOSTON, AND HONORARY MEMBER OF THE PHILOSOPHICAL SOCIETY OF CAMBRIDGE.
FORMERLY PROFESSOR OF MORAL PHILOSOPHY IN THE UNIVERSITY
OF EDINBURGH.**

ADVERTISEMENT. .

SOME apology, I am afraid, is necessary for the length to which this Dissertation has already extended. My original design (as is well known to my friends) was to comprise in ten or twelve sheets all the preliminary matter which I was to contribute to this SUPPLEMENT. But my work grew insensibly under my hands, till it assumed a form which obliged me either to destroy all that I had written, or to continue my Historical Sketches on the same enlarged scale. In selecting the subjects on which I have chiefly dwelt, I have been guided by my own idea of their pre-eminent importance, when considered in connection with the present state of Philosophy in Europe. On some, which I have passed over unnoticed, it was impossible for me to touch, without a readier access to public libraries than I can command in this retirement. The same circumstance will, I trust, account, in the opinion of candid readers, for various other omissions in my performance.

The time unavoidably spent in consulting, with critical care, the numerous Authors referred to in this and in the former part of my Discourse, has encroached so deeply, and to myself so painfully, on the leisure which I had destined for a different purpose, that, at my advanced years, I can entertain but a very faint expectation (though I do not altogether abandon the hope) of finishing my intended Sketch of the Progress of Ethical and Political Philosophy during the Eighteenth Century. An undertaking of a much earlier date has a prior and stronger claim on my attention. At all events, whatever may be wanting to complete my plan, it cannot be difficult for another hand to supply. An Outline is all that should be attempted on such a subject; and the field which it has to embrace will be found incomparably more interesting to most readers than that which has fallen under my review.

Kinncl Housc, August 7, 1821.

DISSERTATION FIRST.

PART II.

IN the farther prosecution of the plan of which I traced the outline in the Preface to the First Part of this Dissertation, I find it necessary to depart considerably from the arrangement which I adopted in treating of the Philosophy of the seventeenth century. During that period, the literary intercourse between the different nations of Europe was comparatively so slight, that it seemed advisable to consider, separately and successively, the progress of the mind in England, in France, and in Germany. But from the era at which we are now arrived, *the Republic of Letters* may be justly understood to comprehend, not only these and other countries in their neighbourhood, but every region of the civilised earth. Disregarding, accordingly, all diversities of language and of geographical situation, I shall direct my attention to the intellectual progress of the species in general; enlarging, however, chiefly on the Philosophy of those parts of Europe, from whence the rays of science have, in modern times, diverged to the other quarters of the globe. I propose also, in consequence of the thickening crowd of useful authors, keeping pace in their numbers with the diffusion of knowledge and of liberality, to allot separate discourses to the history of Metaphysics, of Ethics, and of Politics; a distribution which, while it promises a more distinct and connected view of these different subjects, will furnish convenient resting-places, both to the writer and to the reader, and can scarcely fail to place, in a stronger and more concentrated light, whatever general conclusions may occur in the course of this survey.

The foregoing considerations, combined with the narrow limits assigned to the sequel of my work, will sufficiently account for the contracted scale of some of the following

sketches, when compared with the magnitude of the questions to which they relate, and the peculiar interest which they derive from their immediate influence on the opinions of our own times.

In the case of Locke and Leibnitz, with whom the metaphysical history of the eighteenth century opens, I mean to allow myself a greater degree of latitude. The rank which I have assigned to both in my general plan seems to require, of course, a more ample space for their leading doctrines, as well as for those of some of their contemporaries and immediate successors, than I can spare for metaphysical systems of a more modern date; and as the rudiments of the most important of these are to be found in the speculations either of one or of the other, I shall endeavour, by connecting with my review of their works, those longer and more abstract discussions which are necessary for the illustration of fundamental principles, to avoid, as far as possible, in the remaining part of my discourse, any tedious digressions into the thorny paths of scholastic controversy. The critical remarks, accordingly, which I am now to offer on their philosophical writings, will, I trust, enable me to execute the very slight sketches which are to follow in a manner at once more easy to myself, and more satisfactory to the bulk of my readers.

But what I have chiefly in view in these preliminary observations, is to correct certain misapprehensions concerning the opinions of Locke and of Leibnitz, which have misled (with very few exceptions) all the later historians who have treated of the literature of the eighteenth century. I have felt a more particular solicitude to vindicate the fame of Locke, not only against the censures of his opponents, but against the mistaken comments and eulogies of his admirers, both in England and on the Continent. Appeals to his authority are so frequent in the reasonings of all who have since canvassed the same subjects, that, without a precise idea of his distinguishing tenets, it is impossible to form a just estimate, either of the merits or demerits of his successors. In order to assist my readers in this previous study, I shall endeavour, as far as I can, to make Locke his own commentator; earnestly intreating them, before they proceed to the sequel of this dissertation, to collate carefully those scattered extracts from his works, which, in the following section, they will find brought into contact with each other, with a view to their mutual illustration. My own conviction, I confess, is, that the *Essay on Human Understanding* has been much more generally applauded than read; and if I could only flatter myself with the hope of drawing the attention of the public from the glosses of commentators to the author's text, I should think that I had made a considerable step towards the correction of some radical and prevailing errors, which the supposed sanction of his name has hitherto sheltered from a free examination.

PROGRESS OF METAPHYSICS DURING THE EIGHTEENTH CENTURY.

SECTION I.

Historical and Critical Review of the Philosophical Works of Locke and Leibnitz.

LOCKE.

BEFORE entering on the subject of this section, it is proper to premise, that, although my design is to treat separately of Metaphysics, Ethics, and Politics, it will be impossible to keep these sciences wholly unmixed in the course of my reflections. They all run into each other by insensible gradations; and they have all been happily united in the comprehensive speculations of some of the most distinguished writers of the eighteenth century. The connection between Metaphysics and Ethics is more peculiarly close; the theory of Morals having furnished, ever since the time of Cudworth, several of the most abstruse questions which have been agitated concerning the general principles, both intellectual and active, of the human frame. The inseparable affinity, however, between the different branches of the Philosophy of the Mind, does not afford any argument against the arrangement which I have adopted. It only shows, that it cannot, in every instance, be rigorously adhered to. It shall be my aim to deviate from it as seldom, and as slightly, as the miscellaneous nature of my materials will permit.

JOHN LOCKE, from the publication of whose *Essay on Human Understanding* a new era is to be dated in the History of Philosophy, was born at Wrington in Somersetshire, in 1632. Of his father nothing remarkable is recorded, but that he was a captain in the Parliament's army during the civil wars; a circumstance which, it may be presumed from the son's political opinions, would not be regarded by him as a stain on the memory of his parent.

In the earlier part of Mr Locke's life, he prosecuted for some years, with great ardour, the study of medicine; an art, however, which he never actually exercised as a profession. According to his friend Le Clerc, the delicacy of his constitution rendered this impossible. But, that his proficiency in the study was not inconsiderable, we have good evidence in the dedication prefixed to Dr Sydenham's *Observations on the History and Cure of Acute*

Diseases; ¹ where he boasts of the approbation bestowed on his METHOD by Mr John Locke, who (to borrow Sydenham's own words) "examined it to the bottom; and who, if we consider his genius and penetrating and exact judgment, has scarce any superior, and few equals, now living." The merit of this METHOD, therefore, which still continues to be regarded as a model by the most competent judges, may be presumed to have belonged in part to Mr Locke, ²—a circumstance which deserves to be noticed, as an additional confirmation of what Bacon has so sagaciously taught, concerning the dependence of all the sciences relating to the phenomena, either of Matter or of Mind, on principles and rules derived from the resources of a higher philosophy. On the other hand, no science could have been chosen, more happily calculated than Medicine, to prepare such a mind as that of Locke for the prosecution of those speculations which have immortalized his name; the complicated and fugitive, and often equivocal phenomena of disease, requiring in the observer a far greater portion of discriminating sagacity, than those of Physics, strictly so called; resembling, in this respect, much more nearly, the phenomena about which Metaphysics, Ethics, and Politics, are conversant.

I have said, that the study of Medicine forms one of the best preparations for the study of mind, to such an understanding as Locke's. To an understanding less comprehensive, and less cultivated by a liberal education, the effect of this study is likely to be similar to what we may trace in the works of Hartley, Darwin, and Cabanis; to all of whom we may more or less apply the sarcasm of Cicero on Aristoxenus, the Musician, who attempted to explain the nature of the soul by comparing it to a *Harmony*; *HIIC AB ARTIFICIO SUO NON RECESSIT.* ³ In Locke's *Essay*, not a single passage occurs, savouring of the Anatomical Theatre, or of the Chemical Laboratory.

In 1666, Mr Locke, then in his thirty-fifth year, formed an intimate acquaintance with Lord Ashley, afterwards Earl of Shaftesbury; from which period a complete change took place, both in the direction of his studies, and in his habits of life. His attention appears to

¹ Published in the year 1676.

² It is remarked of Sydenham, by the late Dr John Gregory, "That though full of hypothetical reasoning, it had not the usual effect of making him less attentive to observation; and that his hypotheses seem to have sat so loosely about him, that either they did not influence his practice at all, or he could easily abandon them, whenever they would not bend to his experience."

This is precisely the idea of Locke concerning the true use of hypotheses. "Hypotheses, if they are well made, are at least great helps to the memory, and often direct us to new discoveries." Locke's *Works*, Vol. III. p. 81. See also some remarks on the same subject in one of his letters to Mr Molyneux. (The edition of Locke to which I uniformly refer, is that printed at London in 1812, in Ten Volumes 8vo.)

³ Tusc. Quest. Lib. I.

been then turned, for the first time, to political subjects; and his place of residence transferred from the university to the metropolis. From London (a scene which gave him access to a society very different from what he had previously lived in¹) he occasionally passed over to the Continent, where he had an opportunity of profiting by the conversation of some of the most distinguished persons of his age. In the course of his foreign excursions, he visited France, Germany, and Holland; but the last of these countries seems to have been his favourite place of residence; the blessings which the people there enjoyed, under a government peculiarly favourable to civil and religious liberty, amply compensating, in his view, for what their uninviting territory wanted in point of scenery and of climate. In this respect, the coincidence between the taste of Locke and that of Descartes throws a pleasing light on the characters of both.

The plan of the *Essay on Human Understanding* is said to have been formed as early as 1670; but the various employments and avocations of the Author prevented him from finishing it till 1687, when he fortunately availed himself of the leisure which his exile in Holland afforded him, to complete his long meditated design. He returned to England soon after the Revolution, and published the first edition of his work in 1690; the busy and diversified scenes through which he had passed during its progress, having probably contributed, not less than the academical retirement in which he had spent his youth, to enhance its peculiar and characteristical merits.

Of the circumstances which gave occasion to this great and memorable undertaking, the following interesting account is given in the *Prefatory Epistle to the Reader*. "Five or six friends, meeting at my chamber, and discoursing on a subject very remote from this, found themselves quickly at a stand, by the difficulties that rose on every side. After we had a while puzzled ourselves, without coming any nearer a resolution of those doubts which perplexed us, it came into my thoughts that we took a wrong course, and that, before we set ourselves upon inquiries of that nature, it was necessary to examine our own abilities, and see what objects our understandings were, or were not, fitted to deal with. This I proposed to the company, who all readily assented, and thereupon it was agreed, that this should be our first inquiry. Some hasty and undigested thoughts on a subject I had never before considered, which I set down against our next meeting, gave the first entrance into this discourse, which having been thus begun by chance, was continued by entreaty; written by incoherent parcels, and, after long intervals of neglect, resumed again

¹ Villiers Duke of Buckingham, and the Lord Halifax, are particularly mentioned among those who were delighted with his conversation.

as my humour or occasions permitted; and at last in retirement, where an attendance on my health gave me leisure, it was brought into that order thou now seest it."

Mr Locke afterwards informs us, that "when he first put pen to paper, he thought all he should have to say on this matter would have been contained in one sheet, but that the farther he went the larger prospect he had;—new discoveries still leading him on, till his book grew insensibly to the bulk it now appears in."

On comparing the *Essay on Human Understanding* with the foregoing account of its origin and progress, it is curious to observe, that it is the fourth and last book alone which bears directly on the author's principal object. In this book, it is further remarkable, that there are few, if any, references to the preceding parts of the *Essay*; insomuch that it might have been published separately, without being less intelligible than it is. Hence, it seems not unreasonable to conjecture, that it was the *first* part of the work in the order of composition, and that it contains those leading and fundamental thoughts which offered themselves to the author's mind, when he first began to reflect on the friendly conversation which gave rise to his philosophical researches. The inquiries in the first and second books, which are of a much more abstract, as well as scholastic, nature, than the sequel of the work, probably opened gradually on the author's mind, in proportion as he studied his subject with a closer and more continued attention. They relate chiefly to the origin and to the technical classification of our ideas, frequently branching out into *collateral*, and sometimes into *digressive*, discussions, without much regard to method or connection. The third book (by far the most important of the whole), where the nature, the use, and the abuse of language are so clearly and happily illustrated, seems, from Locke's own account, to have been a sort of *after-thought*; and the two excellent chapters on the *Association of Ideas* and on *Enthusiasm* (the former of which has contributed, as much as any thing else in Locke's writings, to the subsequent progress of Metaphysical Philosophy) were printed, for the first time, in the fourth edition of the *Essay*.

I would not be understood, by these remarks, to undervalue the two first books. All that I have said amounts to this, that the subjects which they treat of are seldom susceptible of any practical application to the conduct of the understanding; and that the author has adopted a new phraseology of his own, where, in some instances, he might have much more clearly conveyed his meaning, without any departure from the ordinary forms of speech. But although these considerations render the two first books inferior in point of general utility to the two last, they do not materially detract from their merit, as a precious accession to the theory of the Human Mind. On the contrary, I do not hesitate to consider them as the richest contribution of well-observed and well-described facts, which

was ever bequeathed to this branch of science by a single individual; and as the indisputable (though not always acknowledged) source of some of the most refined conclusions, with respect to the intellectual phenomena, which have been since brought to light by succeeding inquirers.

After the details given by Locke himself, of the circumstances in which his *Essay* was begun and completed; more especially, after what he has stated of the "discontinued way of writing," imposed on him by the avocations of a busy and unsettled life, it cannot be thought surprising, that so very little of method should appear in the disposition of his materials; or that the opinions which, on different occasions, he has pronounced on the same subject, should not always seem perfectly steady and consistent. In these last cases, however, I am inclined to think that the inconsistencies, if duly reflected on, would be found rather apparent than real. It is but seldom that a writer, possessed of the powerful and upright mind of Locke, can reasonably be suspected of stating propositions in direct contradiction to each other. The presumption is, that, in each of these propositions, there is a mixture of truth, and that the error lies chiefly in the unqualified manner in which the truth is stated; proper allowances not being made, during the fervour of composition, for the partial survey taken of the objects from a particular point of view. Perhaps it would not be going too far to assert, that most of the seeming contradictions which occur in authors animated with a sincere love of truth, might be fairly accounted for by the different aspects which the same object presented to them upon different occasions. In reading such authors, accordingly, when we meet with discordant expressions, instead of indulging ourselves in the captiousness of verbal criticism, it would better become us carefully and candidly to collate the questionable passages; and to study so to reconcile them by judicious modifications and corrections, as to render the oversights and mistakes of our illustrious guides subservient to the precision and soundness of our own conclusions. In the case of Locke, it must be owned, that this is not always an easy task, as the limitations of some of his most exceptionable propositions are to be collected, not from the context, but from different and widely separated parts of his *Essay*.¹

¹ That Locke himself was sensible that some of his expressions required explanation, and was anxious that his opinions should be judged of rather from the general tone and spirit of his work, than from detached and isolated propositions, may be inferred from a passage in one of his notes, where he replies to the animadversions of one of his antagonists (the Reverend Mr Lowde), who had accused him of calling in question the immutability of moral distinctions. "But (says Locke) the good man does well, and as becomes his calling, to be watchful in such points, and to take the alarm, even at expressions, which, standing alone by themselves, might sound ill, and be suspected." (*Locke's Works*, Vol. II. p. 93. Note.)

In a work thus composed *by snatches* (to borrow a phrase of the author's), it was not to be expected, that he should be able accurately to draw the line between his own ideas, and the hints for which he was indebted to others. To those who are well acquainted with his speculations, it must appear evident, that he had studied diligently the metaphysical writings both of Hobbes and of Gassendi; and that he was no stranger to the *Essays* of Montaigne, to the philosophical works of Bacon, or to Malebranche's *Inquiry after Truth*.¹ That he was familiarly conversant with the Cartesian system may be presumed from what we are told by his biographer, that it was *this* which first inspired him with a disgust at the jargon of the schools, and led him into that train of thinking which he afterwards prosecuted so successfully. I do not, however, recollect that he has anywhere in his Essay mentioned the name of any one of these authors.² It is probable, that, when he sat down to write, he found the result of his youthful reading so completely identified with the fruits of his subsequent reflections, that it was impossible for him to attempt a separation of the one from the other; and that he was thus occasionally led to mistake the treasures of memory for those of invention. That this was really the case, may be farther presumed from the peculiar and original cast of his phraseology, which, though in general careless and unpolished, has always the merit of that characteristical unity and *raciness* of style, which demonstrate, that, while he was writing, he conceived himself to be drawing only from his own resources.

With respect to his style, it may be further observed, that it resembles that of a well educated and well informed man of the world, rather than of a recluse student who had made an object of the art of composition. It everywhere abounds with colloquial expressions, which he had probably caught by the ear from those whom he considered as models of good conversation; and hence, though it now seems somewhat antiquated, and not altogether suited to the dignity of the subject, it may be presumed to have contributed its share towards this great object of turning the thoughts of his contemporaries to logical and metaphysical inquiries. The author of the *Characteristics*, who will not be accused of an un-

¹ Mr Addison has remarked, that Malebranche had the start of Locke, by several years, in his notions on the subject of *Duration*. (Spectator, No. 94.) Some other coincidences, not less remarkable, might be easily pointed out in the opinions of the English and of the French philosopher.

² The name of Hobbes occurs in Mr Locke's *Reply to the Bishop of Worcester*. See the Notes on his Essay, b. iv. c. 3. It is curious that he classes Hobbes and Spinoza together, as writers of the same stamp; and that he disclaims any intimate acquaintance with the works of either. "I am not so well read in *Hobbes* and *Spinoza* as to be able to say what were their opinions in this matter, but possibly there be those who will think your Lordship's authority of more use than those justly decried names," &c. &c.

due partiality for Locke, acknowledges, in strong terms, the favourable reception which his book had met with among the higher classes. "I am not sorry, however," says Shaftesbury, to one of his correspondents, "that I lent you Locke's *Essay*, a book that may as well qualify men for business and the world, as for the sciences and a university. No one has done more towards the recalling of philosophy from barbarity, into use and practice of the world, and into the company of the better and politer sort, who might well be ashamed of it in its other dress. No one has opened a better and clearer way to reasoning."

In a passage of one of Warburton's letters to Hurd, which I had occasion to quote in the first part of this Dissertation, it is stated as a fact, that "when Locke first published his *Essay*, he had neither followers nor admirers, and hardly a single approver." I cannot help suspecting very strongly the correctness of this assertion, not only from the flattering terms in which the *Essay* is mentioned by Shaftesbury in the foregoing quotation, and from the frequent allusions to its doctrines by Addison and other popular writers of the same period, but from the unexampled sale of the book, during the fourteen years which elapsed between its publication and Locke's death. Four editions were printed in the space of ten years, and three others must have appeared in the space of the next four; a reference being made to the *sixth* edition by the author himself, in the epistle to the reader, prefixed to all the subsequent impressions. A copy of the thirteenth edition, printed as early as 1748, is now lying before me. So rapid and so extensive a circulation of a work, on a subject so little within the reach of common readers, is the best proof of the established popularity of the author's name, and of the respect generally entertained for his talents and his opinions.

That the *Essay on Human Understanding* should have excited some alarm in the University of Oxford, was no more than the author had reason to expect from his boldness as a philosophical reformer; from his avowed zeal in the cause of liberty, both civil and religious; from the suspected orthodoxy of his Theological Creed; and (it is but candid to add) from the apparent coincidence of his ethical doctrines with those of Hobbes.¹ It is more difficult to account for the long continuance, in that illustrious seat of learning, of the prejudice against the *logic* of Locke (by far the most valuable part of his work), and of that partiality for the *logic* of Aristotle, of which Locke has so fully exposed the futility. In the University of Cambridge, on the other hand, the *Essay on Human Understand-*

¹ See Shaftesbury's First Letter to a Student at the University.

² "It was proposed at a meeting of the heads of houses of the University of Oxford, to censure, and discourage the reading of Locke's *Essay*; and, after various debates among themselves, it was concluded, that each head of a house should endeavour to prevent its being read in his college, without coming to any public censure." (See Des Maizeaux's note on a letter from Locke to Collins. *Locke's Works*, Vol. X. p. 224.)

ing was, for many years, regarded with a reverence approaching to idolatry: and to the authority of some distinguished persons connected with that learned body may be traced (as will afterwards appear) the origin of the greater part of the extravagancies which, towards the close of the last century, were grafted on Locke's errors, by the disciples of Hartley, of Law, of Priestley, of Tooke, and of Darwin.¹

To a person who now reads with attention and candour the work in question, it is much more easy to enter into the prejudices which at first opposed themselves to its complete success, than to conceive how it should so soon have acquired its just celebrity. Something, I suspect, must be ascribed to the political importance which Mr Locke had previously acquired as the champion of religious toleration; as the great apostle of the Revolution; and as the intrepid opposer of a tyranny which had been recently overthrown.

In Scotland, where the liberal constitution of the universities has been always peculiarly favourable to the diffusion of a free and eclectic spirit of inquiry, the philosophy of Locke seems very early to have struck its roots, deeply and permanently, into a kindly and congenial soil. Nor were the errors of this great man implicitly adopted from a blind reverence for his name. The works of Descartes still continue to be studied and admired; and the combined systems of the English and the French metaphysicians served, in many respects, to correct what was faulty, and to supply what was deficient, in either. As to the *ethical* principles of Locke, where they appear to lean towards Hobbism, a powerful antidote against them was already prepared in the Treatise *De Jure Belli et Pacis*, which was then universally and deservedly regarded in this country as the best introduction that had yet appeared to the study of moral science. If Scotland, at ~~the~~ period, produced no eminent authors in these branches of learning, it was not from want of erudition or of talents; nor yet from the narrowness of mind incident to the inhabitants of remote and insulated regions; but from the almost insuperable difficulty of writing in a dialect, which imposed upon an author the double task of at once acquiring a new language, and of unlearning his own.²

¹ I have taken notice, with due praise, in the former part of this discourse, of the metaphysical speculations of John Smith, Henry More, and Ralph Cudworth; all of them members and ornaments of the university of Cambridge about the middle of the seventeenth century. They were deeply conversant in the Platonic Philosophy, and applied it with great success in combating the Materialists and Necessitarians of their times. They carried, indeed, some of their Platonic notions to an excess bordering on mysticism, and may, perhaps, have contributed to give a bias to some of their academical successors towards the opposite extreme. A very pleasing and interesting account of the characters of these amiable and ingenious men, and of the spirit of their philosophy, is given by Burnet in the *History of his Own Times*.

To the credit of Smith and of More it may be added, that they were among the first in England to perceive and to acknowledge the merits of the Cartesian Metaphysics.

² Note (A.)

The success of Locke's *Essay*, in some parts of the Continent,* was equally remarkable; owing, no doubt, in the first instance, to the very accurate translation of it into the French language by Coste, and to the eagerness with which every thing proceeding from the author of the *Letters on Toleration*¹ may be presumed to have been read by the multitude of learned and enlightened refugees, whom the revocation of the edict of Nantz forced to seek an asylum in Protestant countries. In Holland, where Locke was personally known to the most distinguished characters, both literary and political, his work was read and praised by a discerning few, with all the partiality of friendship;² but it does not seem to have made its way into the schools till a period considerably later. The doctrines of Descartes, at first so vehemently opposed in that country, were now so completely triumphant, both among philosophers and divines,³ that it was difficult for a new reformer to obtain a hearing. The case was very nearly similar in Germany, where Leibnitz (who always speaks

¹ The principle of religious toleration was at that time very imperfectly admitted, even by those philosophers who were the most zealously attached to the cause of civil liberty. The great Scottish lawyer and statesman, Lord Stair (himself no mean philosopher, and, like Locke, a warm partizan of the Revolution), seems evidently to have regretted the impunity which Spinoza had experienced in Holland, and Hobbes in England. "Execrabilis Atheus Spinoza adeo impudens est, ut affirmet omnia esse absolute necessaria, et nihil quod est, fuit, aut erit, aliter fieri potuisse, in quo omnes superiores Atheos excessit, aperte negans omnem Deitatem, nihilque præter potentias naturæ agnoscens.

"Vaninus Deitatem non aperte negavit, sed causam illius prodidit, in tractata quem edidit, argumenta pro Dei existentia tanquam futilia et vana rejiciens, adferendo contrarias omnes rationes per modum objectionum, easque prosequendo ut indissolubiles videantur; postea tamen larvam exuit, et atheismum clare professus est, ET JUSTISSIME IN INCLYTA URBE THOLOSA DAMNATUS EST ET CREMATUS.

"Horrendus Hobbesius tertius erat atheismi promotor, qui omnia principia moralia et politica subvertit, eorumque loco naturalem vim et humana pacta, ut prima principia moralitatis, societatis, et politici regiminis substituit: NEC TAMEN SPINOSA AUT HOBBIUS, QUAMVIS IN REGIONIBUS REFORMATIS VIXERINT ET MORTUI SINT, NEDUM EXEMPLA FACTI SUNT IN ATHEORUM TERRORIBUS, UT NE VEL ULLAM PÆNAM SENSERINT."—*Physiol. Nova Experimentalis* (Lugd. Batav. 1666), pp. 16, 17.

² Among those whose society Locke chiefly cultivated while in Holland, was the celebrated Le Clerc, the author of the *Bibliothèque Universelle*, and the *Bibliothèque Choisie*, besides many other learned and ingenious publications. He appears to have been warmly attached to Locke, and embraced the fundamental doctrines of his *Essay* without any slavish deference for his authority. Though he fixed his residence at Amsterdam, where he taught Philosophy and the Belles Lettres, he was a native of Geneva, where he also received his academical education. He is, therefore, to be numbered with Locke's Swiss disciples. I shall have occasion to speak of him more at length afterwards, when I come to mention his controversy with Bayle. At present, I shall only observe, that his *Eloge on Locke* was published in the *Bibliothèque Choisie* (Année 1705), Tom VI.; and that some important remarks on the *Essay on Human Understanding* (particularly on the chapter on Power) are to be found in the 12th Vol. of the same work (Année 1707).

³ Quamvis huic sectæ (Cartesianæ) initio acriter se opposerent Theologi et Philosophi Belgæ, in Academiis tamen eorum hodie (1727), vix alia, quam Cartesianæ principia inculcantur. (Heineccii *Elem. Hist. Philosoph.*) In Gravesande's *Introductio ad Philosophiam*, published in 1736, the name of Locke is not once mentioned. It is probable that this last author was partly influenced by his admiration for Leibnitz, whom he servilely followed even in his physical errors.

coldly of Locke's *Essay*)¹ was then looked up to as the great oracle in every branch of learning and of science. If I am not mistaken, it was in Switzerland, where (as Gibbon observes) "the intermixture of sects had rendered the clergy acute and learned on controversial topics," that Locke's real merits were first appreciated on the Continent with a discriminating impartiality. In Crousaz's *Treatise of Logic* (a book which, if not distinguished by originality of genius, is at least strongly marked with the sound and unprejudiced judgment of the author), we everywhere trace the influence of Locke's doctrines; and, at the same time, the effects of the Cartesian Metaphysics, in limiting those hasty expressions of Locke, which have been so often misinterpreted by his followers.² Nor do

¹ In Lockio sunt quedam particularia non male exposita, sed in summâ longe aberravit à januâ nec naturam mentis veritatisque intellexit.—Leibnitz. Op. Tom. V. p. 355. Ed. Dutens.

M. Locke avoit de la subtilité et de l'adresse, et quelque espèce de métaphysique superficielle qu'il savoit relever. (*Ibid.* pp. 11, 12.)

Heineccius, a native of Saxony, in a *Sketch of the History of Philosophy*, printed in 1728, omits altogether the name of Locke in his enumeration of the logical and metaphysical writers of modern Europe. In a passage of his logic, where the same author treats of *clear and obscure, adequate and inadequate ideas* (a subject on which little or nothing of any value had been advanced before Locke), he observes, in a note, "*Debemus hanc Doctrinam Leibnitio, eamque deinde sequutus est illust. Wolfius.*"

² Of the *Essay on Human Understanding* Crousaz speaks in the following terms: "Clarissimi, et merito celebratissimi Lockii de Intellectu Humano eximium opus, et auctore suo dignissimum, logicis utilissimis semper annumerabitur." (*Præfat.*) If Pope had ever looked into this *Treatise*, he could not have committed so gross a mistake, as to introduce the author into the *Dunciad*, among Locke's Aristotelian opponents; a distinction for which Crousaz was probably indebted to his acute strictures on those passages in the *Essay on Man*, which seem favourable to fatalism.

Prompt at the call, around the goddess roll
Broad hats, and hoods, and caps, a sable shoal;
Thick and more thick the black blockade extends,
A hundred head of Aristotle's friends.
Nor war't thou, Isis! wanting to the day
(Though Christ-church long kept prudishly away).
Each Staunch Polemic, stubborn as a rock,
Each fierce Logician; still expelling Locke,
Come whip and spar, and dash'd through thin and thick
On German Crousaz, and Dutch Burgersdyck.

Warburton, with his usual scurrility towards all Pope's adversaries as well as his own, has called Crousaz a *blundering Sinner*; but a very different estimate of his merits has been formed by Gibbon, who seems to have studied his works much more carefully than the Right Reverend Commentator on the *Dunciad*.

"M. de Crousaz, the adversary of Bayle and Pope, is not distinguished by lively fancy or profound reflection; and even in his own country, at the end of a few years, his name and writings are almost obliterated. But his Philosophy had been formed in the school of Locke, his Divinity in that of Limborch and Le Clerc; in a long and laborious life, several generations of pupils were taught to think, and even to write; his lessons rescued the Academy of Lausanne from Calvinistic prejudices; and he had the rare merit of diffusing a more liberal spirit among the people of the *pagis de Vaud*." (*Gibbon's Memoirs.*)

Crousaz's academical labours appear to have been less useful than his writings; if a judgment on this point may be formed from the sound philosophical principles which he diffused among a numerous race of pupils. One of these (M. Allamand), the friend and correspondent of Gibbon, deserves particularly to be noticed here, on account of two letters published in the posthumous works of that historian, containing a criticism on Locke's argument against innate ideas, so very able and judicious, that it may still be read with advantage by many logicians of no small note in the learned world. Had these letters happened to have sooner attracted my attention, I should not have delayed so long to do this tardy justice to their merits.¹

I am not able to speak with confidence of the period at which Locke's Essay began to attract public notice in France. Voltaire, in a letter to Horace Walpole, asserts, that he

In a subsequent passage Gibbon says, "The logic of Crousaz had prepared me to engage with his master Locke, and his antagonist Bayle; of whom the former may be used as a bridle, and the latter applied as a spur to the curiosity of a young philosopher. (*Ibid.*)

The following details (independently of their reference to Crousaz) are so interesting in themselves, and afford so strong a testimony to the utility of logical studies, when rationally conducted, that I am tempted to transcribe them.

"December 1755. In finishing this year, I must remark how favourable it was to my studies. In the space of eight months, I learned the principles of drawing; made myself completely master of the French and Latin languages, with which I was very superficially acquainted before, and wrote and translated a great deal in both; read Cicero's Epistles ad Familiares, his Brutus, all his Orations, his Dialogues de Amicitia et de Senectute; Terence twice, and Pliny's Epistles. In French, Giannoni's History of Naples, l'Abbé Banier's Mythology, and M. Roehat's Mémoires sur la Suisse, and wrote a very ample relation of my tour. I likewise began to study Greek, and went through the grammar. I began to make very large collections of what I read. But what I esteem most of all,—from the perusal and meditation of De Crousaz's logic, I not only understood the principles of that science, but formed my mind to a habit of thinking and reasoning, I had no idea of before."

After all, I very readily grant, that Crousaz's logic is chiefly to be regarded as the work of a sagacious and enlightened compiler; but even this (due allowance being made for the state of philosophy when it appeared) is no mean praise. "Good sense (as Gibbon has very truly observed) is a quality of mind hardly less rare than genius."

¹ For some remarks of M. Allamand, which approach very near to Reid's Objections to the Ideal Theory, See Note (B.)

Of this extraordinary man Gibbon gives the following account in his *Journal*: "C'est un ministre dans le Pays de Vaud, et un des plus beaux génies que je connoisse. Il a voulu embrasser tous les genres; mais c'est la Philosophie qu'il a le plus approfondi. Sur toutes les questions il s'est fait des systèmes, ou du moins des argumens toujours originaux et toujours ingénieux. Ses idées sont fines et lumineuses, son expression heureuse et facile. Ou lui reproche avec raison trop de raffinement et de subtilité dans l'esprit; trop de fierté, trop d'ambition, et trop de violence dans le caractère. Cet homme, qui auroit pu éclairer ou troubler une nation, vit et mourra dans l'obscurité."

It is of the same person that Gibbon sneeringly says (in the words of Vossius), "*Est sacrificulus in pago, et rusticos decipit.*"

was the first person who^o made the name of Locke known to his countrymen;¹ but I suspect that this assertion must be received with considerable qualifications. The striking coincidence between some of Locke's most celebrated doctrines and those of Gassendi, can scarcely be supposed to have been altogether overlooked by the followers and admirers of the latter; considering the immediate and very general circulation given on the Continent to the *Essay on Human Understanding*, by Coste's French version. The *Gassendists*, too, it must be remembered, formed, even before the death of their master, a party formidable in talents as well as in numbers; including, among other distinguished names, those of Moliere,² Chapelle,³ and Bernier;⁴ all of them eminently calculated to give the tone, on dis-

¹ " Je peux vous assurer qu'avant moi personne en France ne connoissoit la poesie Angloise ; à peine avoit on entendu parler de Locke. J'ai été persecuté pendant trente ans par une nuée de fanatiques pour avoir dit que Locke est l'Hercule de la Métaphysique, qui a posé les bornes de l'Esprit Humain." (Ferney, 1768.)

In the following passage of *the Age of Louis XIV.* the same celebrated writer is so lavish and undistinguishing in his praise of Locke, as almost to justify a doubt whether he had ever read the book which he extols so highly. " Locke seul a développé l'entendement humain, dans un livre ou il n'y a que des vérités; et ce qui rend l'ouvrage parfait, toutes ces vérités sont claires."

² Moliere was in his youth so strongly attached to the Epicurean theories, that he had projected a translation of Lucretius into French. He is even said to have made some progress in executing his design, when a trifling accident determined him, in a moment of ill humour, to throw his manuscript into the fire. The plan on which he was to proceed in this bold undertaking does honour to his good sense and good taste, and seems to me the only one on which a successful version of Lucretius can ever be executed. The didactic passages of the poem were to be translated into prose, and the descriptive passages into verse. Both parts would have gained greatly by this compromise; for, where Lucretius wishes to unfold the philosophy of his master, he is not less admirable for the perspicuity and precision of his expressions, than he is on other occasions, where his object is to detain and delight the imaginations of his readers, for the charms of his figurative diction, and for the bold relief of his images. In instances of the former kind, no modern language can give even the *semblance* of poetry to the theories of Epicurus; while, at the same time, in the vain attempt to conquer this difficulty, the rigorous precision and simplicity of the original are inevitably lost.

The influence of Gassendi's instructions may be traced in several of Moliere's comedies; particularly in the *Femmes Savantes*, and in a little piece *Le Mariage Forcé*, where an Aristotelian and a Cartesian doctor are both held up to the same sort of ridicule, which, in some other of his performances, he has so lavishly bestowed on the medical professors of his time.

³ The joint author, with Bachaumont, of the *Voyage en Provence*, which is still regarded as the most perfect model of that light, easy, and graceful *badinage* which seems to belong exclusively to French poetry. Gassendi who was an intimate friend of his father, was so charmed with his vivacity while a boy, that he condescended to be his instructor in philosophy; admitting, at the same time, to his lessons, two other illustrious pupils, Moliere and Bernier. The life of Chapelle, according to all his biographers, exhibited a complete contrast to the simple and ascetic manners of his master; but, if the following account is to be credited, he missed no opportunity of propagating, as widely as he could, the speculative principles in which he had been educated. " Il étoit fort éloquent dans l'ivresse. Il restoit ordinairement le dernier à table, et se mettoit à expliquer aux valets la philosophie d'Epicure." (*Biographie Universelle*, article *Chapelle*, Paris, 1813.) He died in 1686.

⁴ The well known author of one of our most interesting and instructive books of travels. After his re-

puted questions of Metaphysics, to that numerous class of Parisians of both sexes, with whom the practical lessons, vulgarly imputed to Epicurus, were not likely to operate to the prejudice of his speculative principles. Of the three persons just mentioned, the two last died only a few years before Locke's *Essay* was published; and may be presumed to have left behind them many younger pupils of the same school. One thing is certain, that, long before the middle of the last century, the *Essay on Human Understanding* was not only read by the learned, but had made its way into the circles of fashion at Paris.¹ In what manner this is to be accounted for, it is not easy to say; but the fact will not be disputed by those who are at all acquainted with the history of French literature.

In consequence of this rapid and extensive circulation of the work in question, and the strong impression that it every where produced, by the new and striking contrast which it exhibited to the doctrines of the schools, a very remarkable change soon manifested itself in the prevailing habits of thinking on philosophical subjects. Not that it is to be supposed that the opinions of men, on particular articles of their former creed, underwent a sudden alteration. I speak only of the *general effect* of Locke's discussions, in preparing the thinking part of his readers, to a degree till then unknown, for the unshackled use of their own reason. This has always appeared to me the most characteristic feature of Locke's *Essay*: and *that* to which it is chiefly indebted for its immense influence on the philosophy of the eighteenth century. Few books can be named, from which it is possible to extract more exceptionable passages; but, such is the liberal tone of the author; such the manliness with which he constantly appeals to *reason*, as the paramount authority which, even in religious controversy, every candid disputant is bound to acknowledge; and such the sincerity and simplicity with which, on all occasions, he appears to inquire after truth,

turn from the East, where he resided twelve years at the court of the Great Mogul, he published, at Lyons, an excellent *Abridgment of the Philosophy of Gassendi*, in 8 vols. 12mo; a second edition of which, corrected by himself, afterwards appeared, in seven volumes. To this second edition (which I have never met with) is annexed a Supplement, entitled *Doutes de M. Bernier sur quelques uns des principaux Chapitres de son Abrégé de la Philosophie de Gassendi*. It is to this work, I presume, that Leibnitz alludes in the following passage of a letter to John Bernouilli; and, from the manner in which he speaks of its contents it would seem to be an object of some curiosity. "Frustra quasivi apud typographos librum cui titulus; *Doutes de M. Bernier sur la Philosophie*, in Gallia ante annos aliquot editum et mihi visum, sed nunc non repertum. Vellem autem idéo iterum legere, quia ille *Gassendistorum* fuit Princeps; sed paullo ante mortem, libello hoc edito ingenue professus est, in quibus nec Gassendus nec Cartesius satisfaciant." (Leibnitii et Jo. Bernouilli *Commerc. Epist.* 2 vol. 4to. Laussanæ et Genève, 1745.)

Bernier died in 1688.

¹ A decisive proof of this is afforded by the allusions to Locke's doctrines in the dramatic pieces then in possession of the French stage. See Note (C.)

that the *general effect* of the whole work may be regarded as the best of all antidotes against the errors involved in some of its particular conclusions.¹

To attempt any general review of the doctrines sanctioned, or supposed to be sanctioned, by the name of Locke, would be obviously incompatible with the design of this Discourse; but, among these doctrines, there are *two* of fundamental importance, which have misled so many of his successors, that a few remarks on each form a necessary preparation for some historical details which will afterwards occur. The first of these doctrines relates to the ORIGIN OF OUR IDEAS; the second to THE POWER OF MORAL PERCEPTION, AND THE IMMUTABILITY OF MORAL DISTINCTIONS. On *both* questions, the real opinion of Locke has, if I am not widely mistaken, been very grossly misapprehended or misrepresented, by a large portion of his professed followers, as well as of his avowed antagonists.

I. The objection to which Locke's doctrine concerning the origin of our ideas, or, in other words, concerning the sources of our knowledge, are, in my judgment, liable, I have stated so fully in a former work,² that I shall not touch on them here. It is quite sufficient, on the present occasion, to remark, how very unjustly *this* doctrine (imperfect, on the most favourable construction, as it undoubtedly is) has been confounded with those of Gassendi, of Condillac, of Diderot, and of Horne Tooke. The substance of all that is common in the conclusions of these last writers, cannot be better expressed than in the words of their master Gassendi. "All our knowledge (he observes in a letter to Descartes) appears plainly to derive its origin from the senses; and although you deny the maxim, 'Quicquid est in intellectu præesse debere in sensu,' yet this maxim appears, nevertheless, to be true; since our knowledge is all ultimately obtained by an *influx* or *incursion* from things external; which knowledge afterwards undergoes various modifications by means of analogy, composition, division, amplification, extenuation, and other similar processes, which it is unnecessary to enumerate."³

¹ The maxim which he constantly inculcates is, that "Reason must be our last judge and guide in every thing." (Locke's *Works*, Vol. III. p. 145.) To the same purpose, he elsewhere observes, that, "he who makes use of the light and faculties God has given him, and seeks sincerely to discover truth by those helps and abilities he has, may have this satisfaction in doing his duty as a rational creature; that, though he should miss truth, he will not miss the reward of it. For he governs his assent right, and places it as he should, who in any case or matter whatsoever, believes or disbelieves, according as reason directs him. He that does otherwise, transgresses against his own light, and misuses those faculties which were given him to no other end, but to search and follow the clearer evidence and greater probability." (*Ibid.* p. 125.)

² *Philosophical Essays*.

³ "Deinde omnis nostra notitia videtur plane ducere originem à sensibus; et quamvis tu neges quicquid est in intellectu præesse debere in sensu, videtur id esse nihilominus verum, cum nisi solâ incursione

This doctrine of Gassendi's coincides exactly with that ascribed to Locke by Diderot and by Horne Tooke; and it differs only verbally from the more concise statement of

Κατα περιπτωσιν, ut loquuntur, fiat; perficiatur tamen analogia, compositione, divisione, ampliacione, extenuacione, aliisque similibus modis, quos commemorare nihil est necesse." (*Objections in Meditationem Secundam.*)

This doctrine of Gassendi's is thus very clearly stated and illustrated, by the judicious authors of the *Port Royal Logic*. "Un philosophe qui est estimé dans le monde commence sa logique par cette proposition: *Omnis idea orsum ducit a sensibus.* Toute idée tire son origine des sens. Il avoue néanmoins que toutes nos idées n'ont pas été dans nos sens telles qu'elles sont dans notre esprit: mais il prétend qu'elles ont au moins été formées de celles qui ont passé par nos sens, ou par composition, comme lorsque des images séparées de l'or et d'une montagne, on s'en fait une montagne d'or; ou par ampliacion et diminution, comme lorsque de l'image d'un homme d'une grandeur ordinaire on s'en forme un géant ou un pignée; ou par accommodacion et proportion, comme lorsque de l'idée d'une maison qu'on a vue, on s'en forme l'image d'une maison qu'on n'a pas vue. ET AINSI, dit il, NOUS CONCEVONS DIEU QUI NE PEUT TOMBER SOUS LES SENS, SOUS L'IMAGE D'UN VENERABLE VIEILLARD." "Selon cette pensée quoique toutes nos idées ne fussent semblables à quelque corps particulier que nous ayons vu, ou qui ait frappé nos sens, elles seroient néanmoins toutes corporelles, et ne vous representeroient rien qui ne fût entré dans nos sens, au moins par parties. Et ainsi nous ne concevons rien que par des images, semblables à celles qui se forment dans les cerveau quand nous voyons, ou nous nous imaginons des corps." (*L'Art de Penser*, 1. Partic. c. 1.)

The reference made, in the foregoing quotation, to Gassendi's illustration drawn from the idea of God, affords me an opportunity, of which I gladly avail myself, to contrast it with Locke's opinion on the same subject. "How many amongst us will be found, upon inquiry, to fancy God, in the shape of a man, sitting in heaven, and to have many other absurd and unfit conceptions of him? Christians, as well as Turks, have had whole sects owning, or contending earnestly for it, that the Deity was corporeal and of human shape: And although we find few amongst us, who profess themselves *Anthropomorphites* (though some I have met with that own it), yet, I believe, he that will make it his business, may find amongst the ignorant and uninstructed Christians, many of that opinion."* (Vol. I. p. 67.)

"Let the ideas of being and matter be strongly joined either by education or much thought, whilst these are still combined in the mind, what notions, what reasonings will there be about separate spirits? Let custom, from the very childhood, have joined figure and shape to the idea of God, and what absurdities will that mind be liable to about the Deity?" (Vol. II. p. 144.)

The authors of the *Port Royal Logic* have expressed themselves on this point to the very same purpose with Locke; and have enlarged upon it still more fully and forcibly. (See the sequel of the passage above quoted.) Some of their remarks on the subject, which are more particularly directed against Gassendi, have led Brucker to rank them among the advocates for innate ideas (Brucker, *Historia de Ideis*, p. 271), although these remarks coincide exactly in substance with the foregoing quotation from Locke. Like many other modern metaphysicians, this learned and laborious, but not very acute historian, could imagine no intermediate opinion between the theory of innate ideas, as taught by the Cartesians, and the Epicurean account of our knowledge, as revived by Gassendi and Hobbes; and accordingly thought himself entitled to conclude, that whoever rejected the one

* In the judgment of a very learned and pious divine, the bias towards *Anthropomorphism*, which Mr. Locke has here so severely reprehended, is not confined to "ignorant and uninstructed Christians." "If *Anthropomorphism* (says Dr. MacLaine) was banished from theology, orthodoxy would be deprived of some of its most precious phrases, and our confessions of faith and systems of doctrine would be reduced within much narrower bounds."—(Note on Mosheim's *Church History*, Vol. IV. p. 550.)

In Bernier's *Abridgment of Gassendi's Philosophy* (Tom. III. p. 13, et seq.), an attempt is made to reconcile with the Epicurean account of the origin of our knowledge, that more pure and exalted idea of God to which the mind is gradually led by the exercise of its reasoning powers: But I am very doubtful, if Gassendi would have subscribed, in this instance, to the comments of his ingenious disciple. (See pp. 109, 110, of the first part of this Dissertation.)

Condillac, that, “our ideas are nothing more than *transformed* sensations.” “Every idea,” says the first of these writers, “must necessarily, when brought to its state of ultimate decomposition, resolve itself into a *sensible* representation or picture; and since every thing *in* our understanding has been introduced there by the channel of sensation, whatever proceeds *out* of the understanding is either chimerical, or must be able, in returning by the same road, to reattach itself to its sensible archetype. Hence an important rule in philosophy,—that every expression which cannot find an external and a sensible object, to which it can thus establish its affinity, is destitute of signification.” (*Oeuvres de Diderot*, Tom. VI.)

Such is the exposition given by Diderot, of what is regarded in France, as Locke’s great and capital *discovery*; and precisely to the same purpose we are told by Condorcet, that “Locke was the first who proved that *all our ideas are compounded of sensations*.” (*Esquisse Historique*, &c.)

If this were to be admitted as a fair account of Locke’s opinion, it would follow, that he has not advanced a single step beyond Gassendi and Hobbes; both of whom have repeatedly expressed themselves in nearly the same words with Diderot and Condorcet. But al-

must necessarily have adopted the other. The doctrines of Locke and of his predecessor Arnauld will be found, on examination, *essentially different* from both.

Persons little acquainted with the metaphysical speculations of the two last centuries are apt to imagine, that when “all knowledge is said to have its origin in the senses,” nothing more is to be understood than this, that it is by the impressions of external objects on our organs of perception, that the *dormant powers* of the understanding are at first awakened. The foregoing quotation from Gassendi, together with those which I am about to produce from Diderot and Condorcet, may, I trust, be useful in correcting this very common mistake; all of these quotations explicitly asserting, that the external senses furnish not only the *occasions* by which our intellectual powers are excited and developed, but all the *materials* about which our thoughts are conversant; or, in other words, that it is impossible for us to think of any thing, which is not either a sensible image, or the result of sensible images combined together, and transmuted into new forms by a sort of logical chemistry. That the powers of the understanding would for ever continue dormant, were it not for the action of things *external* on the bodily frame, is a proposition now universally admitted by philosophers. Even Mr Harris and Lord Monboddo, the two most zealous, as well as most learned, of Mr Locke’s adversaries in England, have, in the most explicit manner, expressed their assent to the common doctrine. “The first class of ideas (says Monboddo) is produced from ideas furnished by the senses; the second arises from the operations of the mind upon these materials: for I do not deny, that in this our present state of existence, all our ideas, and all our knowledge, are ultimately to be derived from sense and matter.” (Vol. I. p. 44. 2d Ed.) Mr. Harris, while he holds the same language, points out, with greater precision, the essential difference between his philosophy and that of the Hobbists. “Though sensible objects may be the destined medium to awaken the dormant energies of man’s understanding, yet are those energies themselves no more contained in sense, than the explosion of a cannon in the spark which gave it fire.” (*Hermes*.) (On this subject see *Elements of the Philosophy of the Human Mind*, Vol. I. chap. i. sect. 4.)

To this doctrine I have little doubt that Descartes himself would have assented, although the contrary opinion has been generally supposed by his adversaries to be virtually involved in his *Theory of Innate Ideas*. My reason for thinking so, the reader will find stated in Note (D.)

though it must be granted, in favour of their interpretation of his language, that various detached passages may be quoted from his work, which seem, on a superficial view, to justify their comments, yet of what weight, it may be asked, are these passages, when compared with the stress laid by the author on *Reflection*, as an original source of our ideas, altogether different from *Sensation*? “The other fountain,” says Locke, “from which experience furnisheth the understanding with ideas, is the perception of the operations of our own minds within us, as it is employed about the ideas it has got; which operations, when the soul comes to *reflect on* and consider, do furnish the understanding with another set of ideas, which could not be had from things without; and such are *Perception, Thinking, Doubting, Believing, Reasoning, Knowing, Willing*, and all the different actings of our own minds, which, we being conscious of, and observing in ourselves, do from these receive into our understandings ideas as distinct as we do from bodies affecting our senses. This source of ideas every man has wholly in himself: And though it be not sense, *as having nothing to do with external objects*, yet it is very like it, and might properly enough be called *internal sense*. But as I call the other SENSATION, so I call this REFLECTION; the ideas it affords being such only as the mind gets by *reflecting* on its own operations within itself.”¹ (Locke’s *Works*, Vol. I. p. 78.)

“The understanding seems to me not to have the least glimmering of any ideas which it doth not receive from one of these two. *External objects furnish the mind with the ideas of sensible qualities; and the mind furnishes the understanding with ideas of its own operations.*” (*Ibid.* p. 79.)

In another part of the same chapter, Locke expresses himself thus: “Men come to be furnished with fewer or more simple ideas from without, according as the objects they converse with afford greater or less variety; and from the operations of their minds within, according as they more or less REFLECT on them. For, though he that contemplates the operations of his mind, cannot but have plain and clear ideas of them; yet, unless he turn his thoughts that way, and consider them *attentively*, he will no more have clear and distinct ideas of all the operations of his mind, and all that may be observed therein, than he will have all the particular ideas of any landscape, or of the parts and motions of a clock, who will not turn his eyes to it, and with attention heed all the parts of it. The picture, or clock, may be so placed, that they may come in his way every day; but yet he will have but a confused idea of all the parts they are made up of, till he applies himself with attention to consider them in each particular.

¹ Note (E.)

“ And hence we see the reason why it is pretty late before most children get ideas of the operations of their own minds ; and some have not any very clear or perfect ideas of the greatest part of them all their lives. . . . Children, when they first come into it, are surrounded with a world of new things, which, by a constant solicitation of their senses, draw the mind constantly to them,—forward to take notice of new, and apt to be delighted with the variety of changing objects. Thus, the first years are usually employed and directed in looking abroad. Men’s business in them is to acquaint themselves with what is to be found without ; and so growing up in a constant attention to outward sensations, seldom make any considerable reflection on what passes within them, till they come to be of riper years ; and some scarce ever at all.” (*Ibid.* pp. 80, 81.)

I beg leave to request more particularly the attention of my readers to the following paragraphs :

“ If it be demanded, *when a man begins to have any ideas?* I think the true answer is, when he first has any *sensation*. . . . I conceive that ideas in the understanding are coëval with *sensation* ; which is such an impression or motion, made in some part of the body, as produces some perception in the understanding. It is about these impressions made on our senses by outward objects, that the mind seems *first* to employ itself in such operations as we call *Perception, Remembering, Consideration, Reasoning, &c.*

“ In time, the mind comes to reflect on its own operations, and about the ideas got by sensation, and thereby stores itself with a new set of ideas, which I call *ideas of reflection*. These impressions that are made on our senses by objects extrinsical to the mind ; and *its own operations, proceeding from powers intrinsical and proper to itself* (which, when reflected on by itself, become also objects of its contemplation), are, as I have said, *the original of all knowledge.*”¹ (*Ibid.* pp. 91, 92.)

¹ The idea attached by Locke in the above passages to the word *Reflection* is clear and precise. But in the course of his subsequent speculations, he does not always rigidly adhere to it, frequently employing it in that more extensive and popular sense in which it denotes the attentive and deliberate consideration of any object of thought, whether relating to the external or to the internal world. It is in this sense he uses it when he refers to Reflection our ideas of Cause and Effect, of Identity and Diversity, and of *all other relations*. “ All of these (he observes) *terminate in, and are concerned about,* those simple ideas, either of Sensation or Reflection, which I think to be the whole materials of all our knowledge.” (Book II. c. xxv. sect. 9.) From this explanation it would appear that Locke conceived it sufficient to justify his account of the origin of our knowledge, if it could be shown that all our ideas *terminate in, and are concerned about,* ideas derived either from Sensation or Reflection, according to which comment it will not be a difficult task to obviate every objection to which his fundamental principle concerning the two sources of our ideas may appear to be liable.

In this lax interpretation of a principle so completely interwoven with the whole of his philosophy, there is undoubtedly a departure from logical accuracy ; and the same remark may be extended to the vague

A few other scattered sentences, collected from different parts of Locke's *Essay*, may throw additional light on the point in question.

“ I know that people, whose thoughts are immersed in matter, and have so subjected their minds to their senses, that they seldom reflect on any thing beyond them, are apt to say, they cannot comprehend a *thinking* thing, which perhaps is true: But I affirm, when they consider it well, they can no more comprehend an *extended* thing.

“ If any one say, he knows not what 'tis thinks in him; he means, he knows not what the substance is of that thinking thing: No more, say I, knows he what the substance is of that solid thing. Father, if he says, he knows not *how* he thinks; I answer, Neither knows he *how* he is extended; *how* the solid parts of body are united, or cohere together to make extension.” (Vol. II. p. 22.)

“ I think we have as many and as clear ideas belonging to mind, as we have belonging to body, the substance of each being equally unknown to us; and the idea of thinking in mind as clear as of extension in body; and the communication of motion by thought which we attribute to mind, is as evident as that by impulse, which we ascribe to body. Constant experience makes us sensible of both of these, though our narrow understandings can comprehend neither.¹

“ To conclude; Sensation convinces us, that there are solid extended substances; and Reflection, that there are thinking ones: Experience assures us of the existence of such beings; and that the one hath a power to move body by impulse, the other by thought; *this* we cannot doubt of. But beyond these ideas, as received from their proper sources, our faculties will not reach. If we would inquire farther into their nature, causes, and

and indefinite use which he occasionally makes of the word *Reflection*; a word which expresses the peculiar and characteristic doctrine, by which his system is distinguished from that of the Gassendists and Hobbiists. All this, however, serves only to prove still more clearly, how widely remote his real opinion on this subject was from that commonly ascribed to him by the French and German commentators. For my own part, I do not think (notwithstanding some casual expressions which may seem to favour the contrary supposition) that Locke would have hesitated for a moment to admit, with Cudworth and Price, that the *Understanding* is itself a source of new ideas. That it is by *Reflection* (which, according to his own definition, means merely the exercise of the *Understanding* on the internal phenomena) that we get our ideas of memory, imagination, reasoning, and of all other intellectual powers, Mr. Locke has again and again told us; and from this principle it is so obvious an inference, that all the simple ideas which are necessarily implied in our intellectual operations, are ultimately to be referred to the same source, that we cannot reasonably suppose a philosopher of Locke's sagacity to admit the former proposition, and to withhold his assent to the latter.

¹ In transcribing this paragraph, I have taken the liberty to substitute the word *Mind* instead of *Spirit*. The two words were plainly considered by Locke, on the present occasion, as quite synonymous; and the latter (which seems to involve a theory concerning the nature of the thinking principle) is now almost universally rejected by English metaphysicians from their Philosophical Vocabulary.

manner, we perceive not the nature of Extension clearer than we do of Thinking. If we would explain them any farther, one is as easy as the other; and there is no more difficulty to conceive *how* a substance we know not should by *thought* set body into motion, than how a substance we know not should, by *impulse*, set body into motion." (*Ibid.* pp. 26, 27.)

The passage in Locke which, on a superficial view, appears the most favourable to the misinterpretation put on his account of the Sources of our Knowledge, by so many of his professed followers, is, in my opinion, the following:

"It may also lead us a little towards the original of all our notions and knowledge, if we remark, how great a dependence our words have on common sensible ideas; and how those which are made use of to stand for actions and notions quite removed from sense, have their rise from thence, and from obvious sensible ideas are transferred to more abstruse significations, and made to stand for ideas that come not under the cognizance of our senses; *v. g. to imagine, apprehend, comprehend, adhere, conceive, instil, disgust, disturbance, tranquillity, &c.* are all words taken from the operations of sensible things, and applied to certain modes of thinking. *Spirit*, in its primary signification, is breath; *angel*, a messenger: *and I doubt not, but if we could trace them to their sources, we should find, in all languages, the names which stand for things that fall not under our senses, to have had their first rise from sensible ideas.* By which we may give some kind of guess what kind of notions they were, and whence derived, which filled their minds who were the first beginners of languages; and how nature, even in the naming of things, unawares suggested to men the originals and principles of all their knowledge."

So far the words of Locke coincide very nearly, if not exactly, with the doctrines of Hobbes and of Gassendi; and I have not a doubt, that a mistaken interpretation of the clause which I have distinguished by *italics*, furnished the germ of all the mighty *discoveries* contained in the *Επεα πρποιντα*. If Mr Tooke, however, had studied with due attention the import of what immediately follows, he must have instantly perceived how essentially different Locke's real opinion on the subject was from what he conceived it to be.—
 "Whilst to give names, that might make known to others any operations they felt in themselves, or any other ideas that came not under their senses, they were fain to borrow words from ordinary known ideas of sensation, by that means to make others the more easily to conceive those operations they experienced in themselves, which made no outward sensible appearances; and then, when they had got known and agreed names, to signify those internal operations of their own minds, they were sufficiently furnished to make known by words all their other ideas; since they could consist of nothing but either of

outward sensible perceptions, or of the inward operations of their minds about them." (Vol. II. pp. 147, 148.)

From the sentences last quoted, it is manifest, that when Locke remarked the *material* etymology of all our language about mind, he had not the most distant intention to draw from it any inference which might tend to identify the sensible images which this language presents to the fancy, with the metaphysical notions which it figuratively expresses. Through the whole of his *Essay*, he uniformly represents *sensation* and *reflection* as radically distinct sources of knowledge; and, of consequence, he must have conceived it to be not less unphilosophical to attempt an explanation of the phenomena of mind by the analogy of matter, than to think of explaining the phenomena of matter by the analogy of mind. To this fundamental principle concerning the origin of our ideas, he has added, in the passage now before us, That, as our knowledge of mind is posterior in the order of time to that of matter (the first years of our existence being necessarily occupied about objects of sense), it is not surprising, that "when men wished to give names that might make known to others any operations they felt in themselves, or any other ideas that came not under their senses, they should have been fain to borrow words from ordinary known ideas of sensation, by that means to make others the more easily to conceive those operations which make no outward sensible appearances." According to this statement, the purpose of these "borrowed" or metaphorical words is not (as Mr Tooke concluded) to explain the nature of the operations, but to direct the attention of the hearer to that internal world, the phenomena of which he can only learn to comprehend by the exercise of his own power of reflection. If Locke has nowhere affirmed so explicitly as his predecessor Descartes, that "nothing conceivable by the power of imagination can throw any light on the operations of thought," it may be presumed that he considered this as unnecessary, after having dwelt so much on *reflection* as the exclusive source of all our ideas relating to mind; and on the peculiar difficulties attending the exercise of this power, in consequence of the effect of early associations in confounding together our notions of mind and of matter.

The misapprehensions so prevalent on the Continent, with respect to Locke's doctrine on this most important of all metaphysical questions, began during his own lifetime; and were countenanced by the authority of no less a writer than Leibnitz, who always represents Locke as a partizan of the scholastic maxim, *Nihil est in intellectu quod non fuerit in sensu*.—"Nempe (says Leibnitz in reply to this maxim) nihil est in intellectu quod non fuerit in sensu, nisi ipse intellectus."¹ The remark is excellent, and does honour to the

¹ *Opera*, Tom. V. pp. 358, 359.

That the same mistake still keeps its ground among many foreign writers of the highest class, the following

acuteness of the critic; but it is not easy to conceive on what grounds it should have been urged as an objection to a writer, who has insisted so explicitly and so frequently on re-

passage affords a sufficient proof: "Leibnitz a combattu avec une force de dialectique admirable le Systême de Locke, qui attribue toutes nos idées à nos sensations. On avoit mis en avant cet axiome si connu, qu'il n'y avoit rien dans l'intelligence qui n'eut été d'abord dans les sensations, et Leibnitz y ajouta cette sublime restriction, si ce n'est l'intelligence elle-meme. De ce principe dérive toute la philosophie nouvelle qui exerce tant d'influence sur les esprits en Allemagne." (*Mad. de Staël de l'Allemagne*, Tom. III. p. 65.)

I observed in the First Part of this Dissertation (page 67), that this sublime restriction on which so much stress has been laid by the partizans of the German school, is little more than a translation of the following words of Aristotle: *Και αὐτός δὲ νοῦς νοητός ἐστιν, ὥσπερ τὰ νοητὰ ἐπὶ μὲν γὰρ τῶν ἀνελύ ὄλης, τὸ αὐτὸ ἐστὶ τὸ νοῦν καὶ τὸ νοούμενον.* (*De Anima*, Lib. III. cap. v.)

As to Locke, the same injustice which he received from Leibnitz was very early done to him in his own country. In a tract printed in 1697, by a mathematician of some note, the Author of the *Essay on Human Understanding* is represented as holding the same opinion with Gassendi concerning the origin of our ideas. "*Ideæ nomine communi sensu utor; earum originem an a sensibus solum, ut Gassendo et Lockio nostrati, cæterisque plurimis visum est, an aliundè, hujus loci non est inquirere.*" (*De Spatio Reali, seu Ente Infinito Conamen Mathematico-Metaphysicum.* Auctore Josepho Raphson, Rcg. Soc. Socio. This tract is annexed to the second edition of a work entitled *Analysis Æquationum Universalis.* Lond. 1702.)

In order to enable my readers more easily to form a judgment on the argument in the text, I must beg leave once more to remind them of the distinction already pointed out between the Gassendists and the Cartesians; the former asserting, that, as all our ideas are derived from the external senses, the intellectual phenomena can admit of no other explanation than what is furnished by analogies drawn from the material world; the latter rejecting these analogies altogether, as delusive, and treacherous lights in the study of mind; and contending, that the exercise of the power of reflection is the only medium through which any knowledge of its operations is to be obtained. To the one or the other of these two classes, all the metaphysicians of the last century may be referred; and even at the present day, the fundamental question which formed the chief ground of controversy between Gassendi and Descartes (I mean the question concerning the proper logical method of studying the mind) still continues the hinge on which the most important disputes relating to the internal world will be found ultimately to turn.

According to this distinction, Locke (notwithstanding some occasional slips of his pen) belongs indisputably to the class of Cartesians; as well as the very small number of his followers who have entered thoroughly into the spirit of his philosophy. To the class of Gassendists, on the other hand, belong all those French metaphysicians, who, professing to tread in Locke's footsteps, have derived all their knowledge of the *Essay on Human Understanding* from the works of Condillac; together with most of the commentators on Locke who have proceeded from the school of Bishop Law. To these may be added (among the writers of later times) Priestley, Darwin, Beddoes, and, above all, Horne Tooke, with his numerous disciples.

The doctrine of Hobbes on this cardinal question coincided entirely with that of Gassendi, and, accordingly, it is not unusual in the present times, among Hobbes's disciples, to ascribe to him the whole merit of that account of the origin of our knowledge, which, from a strange misconception, has been supposed to have been claimed by Locke as his own discovery. But where, it may be asked, has Hobbes said anything about the origin of those ideas which Locke refers to the power of reflection? and may not the numerous observations which Locke has made on this power as a source of ideas peculiar to itself, be regarded as an indirect refutation of that theory which would resolve all the objects of our knowledge into sensa-

reflection as the source of a class of ideas essentially different from those which are derived from *sensation*. To myself it appears, that the words of Leibnitz only convey, in a more concise and epigrammatic form, the substance of Locke's doctrine. Is any thing implied in them which Locke has not more fully and clearly stated in the following sentence?

tions, as their ultimate elements? This was not merely a step beyond Hobbes; but the correction of an error which lies at the very root of Hobbes's system;—an error, under which (it may be added) the greater part of Hobbes's eulogists have the misfortune still to labour.

It is with much regret I add, that a very large proportion of the English writers, who call themselves *Lockists*, and who, I have no doubt, believe themselves to be so in reality, are at bottom (at least in their metaphysical opinions) *Gassendists* or *Hobbists*. In what respect do the following observations differ from the Epicurean theory concerning the origin of our knowledge, as expounded by Gassendi? "The ideas conveyed by sight, and by our other senses, having entered the mind, intermingle, unite, separate, throw themselves into various combinations and postures, and thereby generate new ideas of reflection, strictly so called; such as those of comparing, dividing, distinguishing,—of abstraction, relation, with many others; all which remain with us as stock for our further use on future occasions." I do not recollect any passage, either in Helvetius or Diderot, which contains a more explicit and decided avowal of that Epicurean system of Metaphysics, which it was the great aim both of Descartes and of Locke to overthrow.

In the following conjectures concerning the nature of our ideas, the same author has far exceeded in extravagance any of the Metaphysicians of the French school. "What those substances are, whereof our ideas are the modifications, whether parts of the mind as the members are of our body, or contained in it like naufs in a box, or enveloped by it like fish in water, whether of a spiritual, corporeal, or middle nature between both, I need not now ascertain. All I mean to lay down at present is this, that, in every exercise of the understanding, that which discerns is numerically and substantially distinct from that which is discerned; and that an act of the understanding is not so much our own proper act, as the act of something else operating upon us."

I should scarcely have thought it worth while to take notice of these passages, had not the doctrines contained in the work from which they were taken, been sanctioned in the most unqualified terms by the high authority of Dr Paley. "There is one work (he observes) to which I owe so much, that it would be ungrateful not to confess the obligation: I mean the writings of the late Abraham Tucker, Esq. part of which were published by himself, and the remainder since his death, under the title of the *Light of Nature Pursued*, by Edward Search, Esq." "I have found, in this writer, more original thinking and observation upon the several subjects that he had taken in hand, than in any other, not to say than in all others put together. His talent also for illustration is unrivalled. But his thoughts are diffused through a long, various, and irregular work. I shall account it no mean praise, if I have been sometimes able to dispose into method, to collect into heads and articles, or to exhibit in more compact and tangible masses, what, in that excellent performance, is spread over too much surface." (*Principles of Moral and Political Philosophy*, Preface, pp. 25, 26.)

Of an author whom Dr Paley has honoured with so very warm an eulogy, it would be equally absurd and presumptuous to dispute the merits. Nor have I any wish to detract from the praise here bestowed on him as an original thinker and observer. I readily admit, also, his talent for illustration, although it sometimes leads him to soar into bombast, and more frequently to sink into buffoonery. As an honest inquirer after moral and religious truth, he is entitled to the most unqualified approbation. But, I must be permitted to add, that, as a metaphysician, he seems to me much more fanciful than solid; and, at the same time, to be so rambling, verbose, and excursive, as to be more likely to unsettle than to fix the principles of his reader.

"External objects furnish the mind with the ideas of sensible qualities; and the mind furnishes the understanding with ideas of its own operations." (Locke's *Works*, Vol. I. p. 79.)

The extraordinary zeal displayed by Locke, at the very outset of his work, against the hypothesis of *innate ideas*, goes far to account for the mistakes committed by his commentators, in interpreting his account of the origin of our knowledge. It ought, however, to be always kept in view, in reading his argument on the subject, that it is the *Cartesian* theory of innate ideas which he is here combating; according to which theory (as understood by Descartes), an *innate idea* signifies something coeval in its existence with the mind to which it belongs, and illuminating the understanding before the external senses begin to operate. The very close affinity between this theory, and some of the doctrines of the Platonic school, preyented Leibnitz, it is probable, from judging of Locke's argument against it, with his usual candour; and disposed him hastily to conclude, that the opposition of Locke to Descartes proceeded from views essentially the same with those of Gassendi, and of his other Epicurean antagonists. How very widely he was mistaken in this conclusion, the numerous passages which I have quoted in Locke's own words sufficiently demonstrate.

In what respects Locke's account of the origin of our ideas falls short of the truth, will appear, when the metaphysical discussions of later times come under our review. Enough has been already said to show, how completely this account has been misapprehended, not only by his opponents, but by the most devoted of his admirers;—a misapprehension so very general, and, at the same time, so obviously at variance with the whole spirit of his Essay, as to prove to a demonstration that, in point of numbers, the *intelligent readers* of this celebrated work have hitherto borne but a small proportion to its purchasers and panegyrists. What an illustration of the folly of trusting, in matters of literary history, to the traditionary judgments copied by one commentator, or critic from another, when recourse may so easily be had to the original sources of information!¹

¹ In justice to Dr. Hareley, I must here observe, that, although his account of the origin of our ideas is precisely the same with that of Gassendi, Hobbes, and Condillac (one of his fundamental principles being, that the *ideas of sensation* are the *elements* of which all the rest are compounded),* he has not availed himself, like the other commentators of later times, of the name of Locke to recommend this theory to the favour of his readers. On the contrary, he has very clearly and candidly pointed out the wide and essential distinction between the two systems. "It may not be amiss here to take notice how far the theory of these papers has led me to differ, in respect of logic, from Mr. Locke's excellent *Essay on the Human Understanding*,

* See the *Introduction*, p. 2 of the *Introduction*.

II. Another misapprehension, not less prevalent than the former, with respect to Locke's philosophical creed, relates to the power of moral perception, and the immutability

to which the world is so much indebted for removing prejudices and circumstances, and affording real and useful knowledge.

"First, then, it appears to me, that all the most complex ideas arise from sensation, and that reflection is not a distinct source, as Mr Locke makes it."

This last proposition Hartley seems to have considered as an important and original improvement of his own on Locke's logic; whereas, in fact, it is a relapse into the old Empiricist hypothesis, which it was one of the main objects of Locke's *Essay* to explain.

I would not have enlarged so fully on Locke's account of the origin of our ideas, had not a mistaken view of his argument on this head, served as a ground-work for the whole *Metaphysical Philosophy* of the French *Encyclopédie*. That all our knowledge is derived from our external senses, is everywhere assumed by the conductors of that work as a demonstrated principle; and the credit of this demonstration is uniformly ascribed to Locke, who, we are told, was the first that fully unfolded and established a truth of which his predecessors had only an imperfect glimpse. La Harpe, in his *Lyce*, has, on this account, justly censured the metaphysical phraseology of the *Encyclopédie*, as tending to degrade the intellectual nature of man; while, with a strange inconsistency, he bestows the most unqualified praise on the writings of Condillac. Little did he suspect, when he wrote the following sentences, how much the reasonings of his favourite logician had contributed to pave the way for those conclusions which he reprobates with so much asperity in Diderot and D'Alembert.

"La gloire de Condillac eût-elle été la première d'être le premier élève de Locke; mais Condillac, en entrant, il mérita d'en servir à tous les autres; il répandit même une plus grande lumière sur les découvertes du philosophe Anglois, il les rendit pour ainsi dire sensibles, et c'est grâce à lui qu'elles sont devenues communes et familières. En un mot, la saine Métaphysique ne date en France, que des ouvrages de Condillac, et à ce titre il doit être compté dans le petit nombre d'hommes qui ont avancé la science qu'ils ont cultivée."—(*Lyce*, Tome XV, pp. 136, 137.)

La Harpe proceeds in the same panegyrical strain through more than seventy pages, and concludes his eulogy of Condillac with these words: "Le style de Condillac est clair et pur comme ses conceptions; c'est en general l'esprit le plus juste et le plus lumineux qui ait contribué, dans sa patrie, aux progrès de la bonne philosophie."—(*Ibid.* p. 214.)

La Harpe's account of the power of *Reflection*, will form an appropriate supplement to his comments on Condillac. "L'impression sentie des objets se nomme perception; l'action de l'âme qui les considère, se nomme réflexion. Ce mot, il est vrai, exprime un mouvement physique, celui de se replier sur soi-même ou sur quelque chose; mais toutes nos idées venant des sens, nous sommes souvent obligés de nous servir de termes physiques pour exprimer les opérations de l'âme."—(*Ibid.* p. 158.) In another passage he defines Reflection as follows: "La faculté de réflexion, c'est-à-dire, le pouvoir qu'a notre âme de préparer, rassembler, de combiner les perceptions."—(*Ibid.* p. 183.) How widely do these definitions of *Reflection* differ from that given by Locke; and how exactly do they accord with the Philosophy of Gassendi, of Hobbes, and of Diderot!

In a lately published sketch of the State of French Literature during the eighteenth century (a work, to which the Author's taste and powers as a writer have attained a degree of public estimation something beyond what was due to his philosophical depth and discrimination), there are some shrewd, and, in my opinion, sound remarks, on the moral tendency of that metaphysical system to which Condillac gave so much

ty of mental distinctions. The consideration of such questions, it may at first sight be thought, belongs rather to the history of Ethics than of Metaphysics; but it must be recollected, that, in introducing them here, I follow the example of Locke himself, who has enlarged upon them at considerable length, in his Argument against the Theory of *Innate Ideas*. An *Ethical* disquisition of this sort formed, it must be owned, an awkward introduction to a work on the Human Understanding; but the conclusion on which it is meant to bear is purely of a *Metaphysical* nature; and when combined with the premises from which it is deduced, affords a good illustration of the impossibility, in tracing the progress of these two sciences, of separating completely the history of the one from that of the other.

In what sense Locke's reasonings against *Innate Ideas* have been commonly understood, may be collected from the following passage of an author, who had certainly no wish to do injustice to Locke's opinions.

"The First Book (says Dr Beattie) of the *Essay on Human Understanding*, which, with submission, I think the worst, tends to establish this dangerous doctrine, that the human mind, previous to education and habit, is as susceptible of any one impression as of any other:—a doctrine which, if true, would go near to prove, that truth and virtue are

circulation and celebrity. I shall quote some of his strictures which bear more particularly on the foregoing argument.

"Autrefois, négligeant d'examiner tout ce mécanisme des sens, tous ces rapports directs du corps avec les objets, les philosophes ne s'occupaient que de ce qui se passe au-dedans de l'homme. La science de l'âme, telle a été la noble étude de Descartes, de Pascal, de Malebranche, de Leibnitz. (Why omit in this list the name of Locke?) Peut-être se perdoient-ils quelquefois dans les nuages des hautes régions où ils avoient pris leur vol, peut-être leurs travaux étoient-ils sans application directe; mais du moins ils suivoient une direction élevée, leur doctrine étoit en rapport avec les pensées qui nous agitent quand nous réfléchissons profondément sur nous-mêmes. Cette route conduisoit nécessairement au plus nobles des sciences, à la religion, et à la morale. Elle supposoit dans ceux qui la cultivoient un génie élevé et de vastes méditations.

"On se lassa de les suivre; on traita de vaines subtilités, on flétrit du titre de rêveries scholastiques les travaux de ces grandes esprits. On se jeta dans la science des sensations, espérant qu'elle seroit plus à la portée de l'intelligence humaine. On s'occupa de plus en plus des rapports mécaniques de l'homme avec les objets, et de l'influence de son organisation physique. De cette sorte, la métaphysique alla toujours se rabaisant, au point que maintenant, pour quelques personnes, elle se confond presque avec la physiologie. . . . Le dix-huitième siècle a voulu faire de cette manière d'envisager l'homme un de ses principaux titres de gloire. . . .

"Condillac est le chef de cette école. C'est dans ses ouvrages que cette métaphysique exerce toutes les séductions de la méthode, et de la lucidité; d'autant plus claire, qu'elle est moins profonde. Peu d'écrivains ont obtenu plus de succès. Il réduisit à la portée du vulgaire la science de la pensée, en retranchant tout ce qu'elle avoit d'élevé. Chacun fut surpris et glorieux de pouvoir philosopher si facilement; et l'on eut une grande reconnaissance pour celui à qui l'on devoit ce bienfait. On ne s'aperçut pas qu'il avoit rabaisé la science, au lieu de rendre ses disciples capables d'y atteindre. — (*Tableau de la Littérature Française pendant le dix-huitième Siècle*, pp. 87, 88, 89, 92.)

no better than human contrivances; or, at least, that they have nothing permanent in their nature; but may be as changeable as the inclinations and capacities of men." Dr Beattie, however, candidly and judiciously adds, "Surely this is not the doctrine that Locke meant to establish; but his zeal against innate ideas, and innate principles, put him off his guard, and made him allow too little to instinct, for fear of allowing too much."

In this last remark, I perfectly agree with Dr Beattie; although I am well aware, that a considerable number of Locke's English disciples have not only chosen to interpret the first book of his *Essay* in that very sense in which it appeared to Dr Beattie to be of so mischievous a tendency, but have avowed Locke's doctrine, when thus interpreted, as their own ethical creed. In this number, I am sorry to say, the respectable name of Paley must be included.¹

It is fortunate for Locke's reputation, that, in other parts of his *Essay*, he has disavowed, in the most unequivocal terms, those dangerous conclusions which, it must be owned, the general strain of his first book has too much the appearance of favouring. "He that hath the idea (he observes on one occasion) of an intelligent, but frail and weak being, made by and depending on another, who is omnipotent, perfectly wise, and good, will as certainly know, that man is to honour, fear, and obey God, as that the sun shines when he sees it; nor can he be surer, in a clear morning, that the sun is risen, if he will but open his eyes, and turn them that way. But yet these truths being never so certain, never so clear, he may be ignorant of either, or all of them, who will never take the pains to employ his faculties as he should to inform himself about them." To the same purpose, he has elsewhere said, that "there is a *Law of Nature*, as intelligible to a *rational creature and studier of that law*, as the positive laws of commonwealths." Nay, he has himself, in the most explicit terms, anticipated and disclaimed those dangerous consequences which, it has been so often supposed, it was the chief scope of this introductory chapter to establish. "I would not be mistaken, as if, because I deny an innate law, I thought there were none but positive laws. There is a great deal of difference between an innate law and a law of nature; between something imprinted on our minds in their very original, and something that we, being ignorant of, may attain to the knowledge of, by the use and due application of our natural faculties. And I think they equally forsake the truth, who, running into the contrary extremes, either affirm an innate law, or deny that there is a law knowable by the light of nature, without the help of a positive revelation." (Vol. I. p. 44.) Nor was Locke unaware of the influence on men's lives of their

¹ See *Principles of Moral and Political Philosophy*, Book I. Chap. 5, where the author discusses the question concerning a *moral sense*.

speculative tenets concerning these metaphysical and ethical questions. On this point, which can alone render such discussions interesting to human happiness, he has expressed himself thus: "Let that principle of some of the philosophers, that *all is matter, and that there is nothing else*, be received for certain and indubitable, and it will be easy to be seen, by the writings of some that have revived it again in our days, what consequences it will lead into. . . . Nothing can be so dangerous as principles thus taken up without due questioning or examination; especially if they be such as influence men's lives, and give a bias to all their actions. He that with *Archelaus* shall lay it down as a principle, that right and wrong, honest and dishonest, are defined only by laws, and not by nature, will have other measures of moral rectitude and pravity, than those who take it for granted, that we are under obligations antecedent to all human constitutions." (Vol. III. p. 75.) Is not the whole of this passage evidently pointed at the Epicurean maxims of Hobbes and of Gassendi?¹

Lord Shaftesbury was one of the first who sounded the alarm against what he conceived to be the drift of that philosophy which denies the existence of *innate principles*. Various strictures on this subject occur in the *Characteristics*; particularly in the treatise entitled *Advice to an Author*; but the most direct of all his attacks upon Locke is to be found in his 8th Letter, addressed to a Student at the University. In this letter he observes, that "all those called *free writers* now-a-days have espoused those principles which Mr Hobbes set a foot in this last age."—"Mr Locke (he continues), as much as I honour him on account of other writings (on Government, Policy, Trade, Coin, Education, Toleration, &c.), and as well as I knew him, and can answer for his sincerity as a most zealous Christian and believer, did however go in the self same tract; and is followed by the Tindals, and all the other free authors of our times!

"'Twas Mr Locke that struck the home blow: for Mr Hobbes's character, and base slavish principles, of government, took off the poison of his philosophy. 'Twas Mr Locke that struck at all fundamentals, threw all *order and virtue* out of the world, and made the very ideas of these (which are the same with those of GOD) *unnatural*, and without foundation in our minds. *Innate* is a word he poorly plays upon: the right word, though less

¹ To the above quotations from Locke, the following deserves to be added: "Whilst the parties of men cram their tenets down all men's throats, whom they can get into their power, without permitting them to examine their truth or falsehood, and will not let truth have fair play in the world, nor men the liberty to search after it; what improvements can be expected of this kind? What greater light can be hoped for in the moral sciences? The subject part of mankind in most places might, instead thereof, with Egyptian bondage expect Egyptian darkness, were not the candle of the Lord set up by himself in men's minds, which it is impossible for the breath or power of man wholly to extinguish." Vol. II. pp. 343, 344.

used, is *connatural*. For what has *birth* or progress of the *fœtus* out of the womb, to do in this case?—the question is not about the *time* the ideas entered, or the moment that one body came out of the other; but whether the constitution of man be such, that, being adult and grown up,¹ at such a time, sooner or later (no matter when), the idea and sense of *order*, *administration*, and a GOD, will not infallibly, inevitably, necessarily spring up in him.”

In this last remark Shaftesbury appears to me to place the question about *innate ideas* upon the right and only philosophical footing; and to afford a key to all the confusion running through Locke's argument against their existence. The sequel of the above quotation is not less just and valuable—but I must not indulge myself in any farther extracts. It is sufficient to mention the perfect coincidence between the opinion of Shaftesbury, as here stated by himself, and that formerly quoted in the words of Locke; and, of consequence, the injustice of concluding, from some unguarded expressions of the latter, that there was, at bottom, any essential difference between their real sentiments.²

¹ Lord Shaftesbury should have said, “grown up to the possession and exercise of his reasoning powers.”

² I must, at the same time, again repeat, that the facts and reasonings contained in the introduction to Locke's *Essay* go very far to account for the severity of Shaftesbury's censures on this part of his work. Sir Isaac Newton himself, an intimate friend of Locke's, appears, from a letter of his which I have read in his own handwriting, to have felt precisely in the same manner with the author of the *Characteristics*. Such, at least, were his *first* impressions; although he afterwards requested, with a humility and candour worthy of himself, the forgiveness of Locke for this injustice done to his character. “I beg your pardon (says he) for representing that you struck at the root of morality in a principle you laid down in your book of ideas, and designed to pursue in another book; and that I took you for a Hobbist.” In the same letter Newton alludes to certain unfounded suspicions which he had been led to entertain of the propriety of Locke's conduct in some of their private concerns; adding, with an ingenuous and almost infantine simplicity, “I was so much affected with this, that when one told me you was sickly and would not live, I answered, 'twere better if you were dead. I desire you to forgive me this uncharitableness.” The letter is subscribed, *your most humble and most unfortunate servant, Is. Newton.*•

The rough draught of Mr Locke's reply to these afflicting acknowledgments was kindly communicated to me by a friend some years ago. It is written with the magnanimity of a philosopher, and with the good-humoured forbearance of a man of the world; and it breathes throughout so tender and so unaffected a veneration for the good as well as the great qualities of the excellent person to whom it is addressed, as demonstrates at once the conscious integrity of the writer, and the superiority of his mind to the irritation of little passions. I know of nothing from Locke's pen which does more honour to his temper and character; and I introduce it with peculiar satisfaction, in connection with those strictures which truth has extorted from me on that part of his system which to the moralist stands most in need of explanation and apology.

MR LOCKE TO MR NEWTON.

“SIR,

Oates, 5th October, 1693.

“I have been ever since I first knew you so kindly and sincerely your friend, and thought you so much mine, that I could not have believed what you tell me of yourself, had I had it from any body else. And

• It is dated at the Bull in Shoreditch, London, September 1693; and is addressed, For John Locke, Esq. at Sir Fra. Masham's, Bart. at Oates, in Essex.

Under the title of Locke's *Metaphysical* (or, to speak with more strict precision, his *Logical*) writings, may also be classed his tracts on Education, and on the conduct of the Understanding. These tracts are entirely of a practical nature, and were plainly intended for a wider circle of readers than his *Essay*; but they everywhere bear the strongest marks of the same zeal for extending the empire of Truth and of Reason, and may be justly regarded as parts of the same great design.¹ It has been often remarked, that they display less originality than might have been expected from so bold and powerful a thinker; and, accordingly, both of them have long fallen into very general neglect. It ought, however, to be remembered, that, on the most important points discussed in them, new suggestions are not now to be looked for; and that the great object of the reader should be, not to learn something which he never heard of before, but to learn, among the multi-

though I cannot but be mightily troubled that you should have so many wrong and unjust thoughts of me, yet, next to the return of good offices, such as from a sincere good will I have ever done you, I receive your acknowledgment of the contrary as the kindest thing you could have done me, since it gives me hopes I have not lost a friend I so much valued. After what your letter expresses, I shall not need to say any thing to justify myself to you: I shall always think your own reflection on my carriage both to you and all mankind will sufficiently do that. Instead of that, give me leave to assure you, that I am more ready to forgive you than you can be to desire it; and I do it so freely and fully that I wish for nothing more than the opportunity to convince you that I truly love and esteem you; and that I have still the same good will for you as if nothing of this had happened. To confirm this to you more fully, I should be glad to meet you anywhere, and the rather, because the conclusion of your letter makes me apprehend it would not be wholly useless to you. I shall always be ready to serve you to my utmost, in any way you shall like, and shall only need your commands or permission to do it.

"My book is going to press for a second edition; and, though I can answer for the design with which I write it, yet, since you have so opportunely given me notice of what you have said of it, I should take it as a favour if you would point out to me the places that gave occasion to that censure, that, by explaining myself better, I may avoid being mistaken by others, or unwillingly doing the least prejudice to truth or virtue. I am sure you are so much a friend to both, that, were you none to me, I could expect this from you. But I cannot doubt but you would do a great deal more than this for my sake, who, after all, have all the concern of a friend for you, wish you extremely well, and am, without compliment," &c. &c.

(For the preservation of this precious memorial of Mr Locke, the public is indebted to the descendants of his friend and relation the Lord Chancellor King, to whom his papers and library were bequeathed. The original is still in the possession of the present representative of that noble family; for whose flattering permission to enrich my Dissertation with the above extracts, I feel the more grateful, as I have not the honour of being personally known to his Lordship.)

¹ Mr Locke, it would appear, had once intended to publish his thoughts on the Conduct of the Understanding, as an additional chapter to his *Essay*. "I have lately," says he, in a letter to Mr Molyneux, "got a little leisure to think of some additions to my book against the next edition, and within these few days have fallen upon a subject that I know not how far it will lead me. I have written several pages on it, but the matter, the farther I go, opens the more upon me, and I cannot get sight of any end of it. The title of the chapter will be, *Of the Conduct of the Understanding*, which, if I shall pursue as far as I imagine it will reach, and as it deserves, will, I conclude, make the largest chapter of my *Essay*." (Locke's Works, Vol. IX. p. 407.)

plicity of discordant precepts current in the world, *which* of them were sanctioned, and *which* reprobated by the judgment of Locke. The candid and unreserved thoughts of such a writer upon such subjects as Education, and the culture of the intellectual powers, possess an intrinsic value, which is not diminished by the consideration of their triteness. They not only serve to illustrate the peculiarities of the author's own character and views, but, considered in a practical light, come recommended to us by all the additional weight of his discriminating experience. In this point of view, the two tracts in question, but more especially that on the *Conduct of the Understanding*, will always continue to be interesting manuals to such as are qualified to appreciate the mind from which they proceeded.¹

It must not, however, be concluded from the *apparent* triteness of some of Locke's remarks, to the present generation of readers, that they were viewed in the same light by his own contemporaries. On the contrary, Leibnitz speaks of the *Treatise on Education* as a work of still greater merit than the *Essay on Human Understanding*.² Nor will this judgment be wondered at by those who, abstracting from the habits of thinking in which they have been reared, transport themselves in imagination to the state of Europe a hundred years ago. How flat and nugatory seem now the cautions to parents about watching over those associations on which the dread of spirits in the dark is founded! But how different was the case (even in Protestant countries) till a very recent period of the last century!

I have, on a former occasion, taken notice of the slow but (since the invention of printing) certain steps by which Truth makes its way in the world; "the discoveries, which, in one age, are confined to the studious and enlightened few, becoming, in the next, the established creed of the learned; and, in the third, forming part of the elementary princi-

¹ A similar remark may be extended to a letter from Locke to his friend Mr. Samuel Bold, who had complained to him of the disadvantages he laboured under from a weakness of memory. It contains nothing but what might have come from the pen of one of Newberry's authors; but with what additional interest do we read it, when considered as a comment by Locke on a suggestion of Bacon's! (Locke's *Works*, Vol. X. p. 317.)

It is a judicious reflection of Shenstone's, that "every single observation published by a man of genius, be it ever so trivial, should be esteemed of importance, because he speaks from his own impressions; whereas common men publish common things, which they have perhaps *gleaned* from frivolous writers." I know of few authors to whom this observation applies more forcibly and happily than to Locke, when he touches on the culture of the intellectual powers. His precepts, indeed, are not all equally sound; but they, in general, contain a large proportion of truth, and may always furnish to a speculative mind matter of useful meditation.

² Leib. *Op.* Tom. VI. p. 226.

ples of education." The harmony, in the meantime, which exists among truths of all descriptions, tends perpetually, by blending them into one common mass, to increase the joint influence of the whole; the contributions of individuals to this mass (to borrow the fine allusion of Middleton) "resembling the drops of rain, which, falling separately into the water, mingle at once with the stream, and strengthen the general current." Hence the ambition, so natural to weak minds, to distinguish themselves by paradoxical and extravagant opinions; for *these*, having no chance to incorporate themselves with the progressive reason of the species, are the more likely to immortalize the eccentricity of their authors, and to furnish subjects of wonder to the common compilers of literary history. This ambition is the more general, as so little expence of genius is necessary for its gratification. "Truth (as Mr Hume has well observed) is *one thing*, but errors are numberless;" and hence (he might have added) the difficulty of seizing the former, and the facility of swelling the number of the latter.¹

Having said so much in illustration of Locke's philosophical merits, and in reply to the common charge against his metaphysical and ethical principles, it now only remains for me to take notice of one or two defects in his intellectual character, which exhibit a strong contrast to the general vigour of his mental powers.

Among these defects, the most prominent is, the facility with which he listens to historical evidence, when it happens to favour his own conclusions. Many remarkable instances of this occur in his long and rambling argument (somewhat in the style of Montaigne) against the existence of *innate practical principles*; to which may be added, the degree of credit he appears to have given to the popular tales about mermaids, and to Sir William Temple's idle story of Prince Maurice's "rational and intelligent parrot." Strange! that the same person who, in matters of reasoning, had divested himself, almost to a fault, of all reverence for the opinions of others, should have failed to perceive, that, of all the various sources of error, one of the most copious and fatal is an unreflecting faith in human testimony!

¹ Descartes has struck into nearly the same train of thinking with the above, but his remarks apply much better to the writings of Locke than to his own.

"L'expérience m'apprit, que quoique mes opinions surprennent d'abord, parce qu'elles sont fort différentes des vulgaires, cependant, après qu'on les a comprises on les trouve si simples et si conformes au sens commun, qu'on cesse entièrement de les admirer, et par la même d'en faire cas: parceque tel est le naturel des hommes qu'ils n'estiment que les choses qui leur laissent d'admiration et qu'ils ne possèdent pas tout-à-fait. C'est ainsi que quoique la santé soit le plus grand de tous les biens qui concernent le corps, c'est pourtant celui auquel nous faisons le moins de réflexion, et que nous goutons le moins. Or, la connoissance de la vérité est comme la santé de l'ame; lorsque on la possède on n'y pense plus." (*Lettres*, Tome I. Lettre xliii.)

The disrespect of Locke for the wisdom of antiquity, is another prejudice which has frequently given a wrong bias to his judgment. The idolatry in which the Greek and Roman writers were held by his immediate predecessors, although it may help to account for this weakness, cannot altogether excuse it in a man of so strong and enlarged an understanding. Locke (as we are told by Dr. Warton) “*affected* to depreciate the ancients; which circumstance (he adds), as I am informed from undoubted authority, was the source of perpetual discontent and dispute betwixt him and his pupil, Lord Shaftesbury; who, in many parts of the *Characteristics*, has ridiculed Locke’s philosophy, and endeavoured to represent him as a disciple of Hobbes.” To those who are aware of the direct opposition between the principles of Hobbes, of Montaigne, of Gassendi, and of the other *minute philosophers* with whom Locke sometimes seems unconsciously to unite his strength,—and the principles of Socrates, of Plato, of Cicero, and of all the soundest moralists, both of ancient and of modern times, the foregoing anecdote will serve at once to explain and to palliate the acrimony of some of Shaftesbury’s strictures on Locke’s Ethical paradoxes.¹

With this disposition of Locke to depreciate the ancients, was intimately connected that contempt which he everywhere expresses for the study of Eloquence, and that perversion of taste which led him to consider Blackmore as one of the first of our English poets.² That his own imagination was neither sterile nor torpid, appears sufficiently from the agreeable colouring and animation which it has not unfrequently imparted to his style; but *this* power of the mind he seems to have regarded with a peculiarly jealous and unfriendly eye; confining his view exclusively to its occasional effects in misleading the judgment, and overlooking altogether the important purposes to which it is subservient, both in our intellectual and moral frame. Hence, in all his writings, an inattention to those more attractive aspects of the mind, the study of which (as Burke has well observed), “while it communicates to the taste a sort of philosophical solidity, may be expected to reflect back on the severer sciences some of those graces and elegances, without which the greatest proficiency in these sciences will always have the appearance of something illiberal.”

To a certain hardness of character, not unfrequently united with an insensibility to the charms of poetry and of eloquence, may partly be ascribed the severe and forbidding spirit

¹ Plebei Philosophi (says Cicero) qui a Platone et Socrate, et ab ea familia dissident.

² “All our English poets, except Milton,” says Molyneux in a letter to Locke, “have been mere ballad-makers in comparison to Sir Richard Blackmore.” In reply to which Locke says, “There is, I with pleasure find, a strange harmony throughout between your thoughts and mine.” (Locke’s *Works*, Vol. IX. pp. 423, 426.)

which has suggested some of the maxims in his *Tract on Education*.¹ He had been treated, himself, it would appear, with very little indulgence by his parents; and probably was led by that filial veneration which he always expressed for their memory, to ascribe to the early habits of self-denial imposed on him by their ascetic system of ethics, the existence of those moral qualities which he owed to the regulating influence of his own reason in fostering his natural dispositions; and which, under a gentler and more skilful culture, might have assumed a still more engaging and amiable form. His father, who had served in the Parliament's army, seems to have retained through life that austerity of manners which characterized his puritanical associates; and, notwithstanding the comparative enlargement and cultivation of Mr Locke's mind, something of this hereditary leaven, if I am not mistaken, continued to operate upon many of his opinions and habits of thinking. If, in the *Conduct of the Understanding*, he trusted (as many have thought) too much to nature, and laid too little stress on logical rules, he certainly fell into the opposite extreme in everything connected with the culture of the heart; distrusting nature altogether, and placing his sole confidence in the effects of a systematical and vigilant discipline. That the great object of education is not to thwart and disturb, but to study the aim, and to facilitate the accomplishment of her beneficial arrangements, is a maxim, one should think, obvious to common sense; and yet it is only of late years that it has begun to gain ground even among philosophers. It is but justice to Rousseau to acknowledge, that the zeal and eloquence with which he has enforced it, go far to compensate the mischievous tendency of some of his other doctrines.

To the same causes it was probably owing, that Locke has availed himself so little in his *Conduct of the Understanding*, of his own favourite doctrine of the Association of Ideas. He has been, indeed, at sufficient pains to warn parents and guardians of the mischievous consequences to be apprehended from this part of our constitution, if not diligently watched over in our infant years. But he seems to have altogether overlooked the positive and immense resources which might be derived from it, in the culture and amelioration, both of our intellectual and moral powers;—in strengthening (for instance), by early *habits* of right thinking, the authority of reason and of conscience;—in blending with our best feelings the congenial and ennobling sympathies of taste and of fancy;—and in identifying, with the first workings of the imagination, those pleasing views of the order of the universe,

¹ Such, for example, as this, that "a child should never be suffered to have what he craves, or *so much as speaks for*, much less if he cries for it!" A maxim (as his correspondent Molyneux observes) "which seems to bear hard on the tender spirits of children, and the natural affections of parents." (*Locke's Works*, Vol. IX. p. 319.)

which are so essentially necessary to human happiness. A law of our nature, so mighty and so extensive in its influence, was surely not given to man in vain; and the fatal *purchase* which it has, in all ages, afforded to Machiavellian statesmen, and to political religionists, in carrying into effect their joint conspiracy against the improvement and welfare of our species, is the most decisive proof of the manifold uses to which it might be turned in the hands of instructors, well disposed and well qualified humbly to co-operate with the obvious and unerring purposes of Divine Wisdom.

A more convenient opportunity will afterwards occur for taking some notice of Locke's writings on Money and Trade, and on the Principles of Government. They appear to me to connect less naturally and closely with the literary history of the times when they appeared, than with the systematical views which were opened on the same subjects about fifty years afterwards, by some speculative politicians in France and in England. I shall, therefore, delay any remarks on them which I have to offer, till we arrive at the period, when the questions to which they relate began everywhere to attract the attention of the learned world, and to be discussed on those general principles of expediency and equity which form the basis of the modern science of Political Economy. With respect to his merits as a logical and metaphysical reformer, enough has been already said for this introductory section: but I shall have occasion, more than once, to recur to them in the following pages, when I come to review those later theories, of which the germs or rudiments may be distinctly traced in his works; and of which he is, therefore, entitled to divide the praise with such of his successors as have reared to maturity the prolific seeds scattered by his hand.¹

SECTION II.

Continuation of the Review of Locke and Leibnitz.

LEIBNITZ.

INDEPENDENTLY of the pre-eminent rank, which the versatile talents, and the universal learning of Leibnitz entitle him to hold among the illustrious men who adorned the Continent of Europe during the eighteenth century, there are other considerations which have

¹ And yet with what modesty does Locke speak of his own pretensions as a Philosopher! "In an age that produces such masters as the great Huygenius and the incomparable Mr Newton, it is ambition enough to be employed as an underlabourer in clearing the ground a little, and removing some of the rubbish that lies in the way to knowledge." (*Essay on Human Understanding. Epistle to the Reader.*) See Note (F.)

determined me to unite his name with that of Locke, in fixing the commencement of the period, on the history of which I am now to enter. The school of which he was the founder was strongly discriminated from that of Locke, by the general spirit of its doctrines; and to this school a large proportion of the metaphysicians, and also of the mathematicians of Germany, Holland, France, and Italy, have, ever since his time, had a decided leaning. On the fundamental question, indeed, concerning the *Origin of our Knowledge*, the philosophers of the Continent (with the exception of the Germans, and a few eminent individuals in other countries) have, in general, sided with Locke, or rather with Gassendi; but, in most other instances, a partiality for the opinions, and a deference for the authority of Leibnitz, may be traced in their speculations, both on metaphysical and physical subjects. Hence a striking contrast between the characteristical features of the continental philosophy, and those of the contemporary systems which have succeeded each other in our own island; the great proportion of our most noted writers, notwithstanding the opposition of their sentiments on particular points, having either attached themselves, or professed to attach themselves, to the method of inquiry recommended and exemplified by Locke.

But the circumstance which chiefly induced me assign to Leibnitz so prominent a place in this historical sketch, is the extraordinary influence of his industry and zeal, in uniting, by a mutual communication of intellectual lights and of moral sympathies, the most powerful and leading minds scattered over Christendom. Some preliminary steps towards such an union had been already taken by Wallis in England, and by Mersenne in France; but the *literary commerce*, of which they were the centres, was confined almost exclusively to Mathematics and to Physics; while the comprehensive correspondence of Leibnitz extended alike to every pursuit interesting to man, either as a speculative or as an active being. From this time forward, accordingly, the history of philosophy involves, in a far greater degree than at any former period, the general history of the human mind; and we shall find, in our attempts to trace its farther progress, our attention more and more irresistibly withdrawn from local details to more enlarged views of the globe which we inhabit. A striking change in this literary commerce among nations took place, at least in the western parts of Europe, before the death of Leibnitz; but, during the remainder of the last century, it continued to proceed with an accelerated rapidity over the whole face of the civilized world. A multitude of causes, undoubtedly, conspired to produce it; but I know of no individual whose name is better entitled, than that of Leibnitz, to mark the era of its commencement.¹

¹ The following maxims of Leibnitz deserve the serious attention of all who have at heart the improvement of mankind:

I have already, in treating of the philosophy of Locke, said enough, and perhaps more than enough, of the opinion of Leibnitz concerning the origin of our knowledge. Although expressed in a different phraseology, it agrees in the most essential points with the *innate ideas* of the Cartesians; but it approaches still more nearly to some of the mystical speculations of Plato. The very exact coincidence between the language of Leibnitz on this question, and that of his contemporary Cudworth, whose mind, like his own, was deeply tinctured with the Platonic Metaphysics, is not unworthy of notice here, as an historical fact; and it is the only remark on this part of his system which I mean to add at present to those in the preceding history.

“The *seeds* of our acquired knowledge,” says Leibnitz, “or, in other words, our *ideas*, and the eternal truths which are derived from them, are contained in the mind itself; nor is this wonderful, since we know by our own consciousness, that we possess within ourselves the ideas of *existence*, of *unity*, of *substance*, of *action*, and other ideas of a similar nature.” To the same purpose, we are told by Cudworth, that “the mind contains in itself virtually (as the future plant or tree is contained in the *seed*) general notions of all things which unfold and discover themselves as occasions invite, and proper circumstances occur.”

The metaphysical theories, to the establishment of which Leibnitz chiefly directed the force of his genius, are the doctrine of *Pre-established Harmony*; and the scheme of *Optimism*, as new modelled by himself. On neither of these heads will it be necessary for me long to detain my readers.

1. According to the system of *Pre-established Harmony*, the human mind and human body are two independent but constantly correspondent machines;—adjusted to each other like two unconnected clocks, so constructed, that, at the same instant, the one should *point* the hour, and the other *strike* it. Of this system the following summary and illustration are given by Leibnitz himself, in his Essay entitled *Theodicæa*:

“I cannot help coming into this notion, that God created the *soul* in such manner at first, that it should *represent* within itself all the simultaneous changes in the body; and that he has made the body also in such manner, as that it must of itself do what the soul wills:—So that the laws which make the thoughts of the soul follow each other in regular

“On trouve dans le monde plusieurs personnes bien intentionnées; mais le mal est, qu’elles ne s’entendent point, et ne travaillent point de concert. S’il y avoit moyen de trouver une espèce de glu pour les réunir, on feroit quelque chose. Le mal est souvent que les gens de bien ont quelques caprices ou opinions particulières, qui font qu’ils sont contraires entr’eux L’esprit sectaire consiste proprement dans cette prétention de vouloir que les autres se reglent sur nos maximes, au lieu qu’on se devoit contenter de voir qu’on aille au but principal.” (Leib. *Op.* Tom. I. p. 740.)

succession, *must* produce *images* which shall be coincident with the impressions made by external objects upon our organs of sense; while the laws by which the motions of the body follow each other, are likewise so coincident with the thoughts of the soul, as to give to our *volitions* and *actions* the very same appearance, as if the latter were really the natural and the necessary consequences of the former." (Leib. *Op.* I. p. 163.) Upon another occasion he observes, that "everything goes on in the soul as if it had no body, and that everything goes on in the body as if it had no soul." (*Ibid.* II. p. 44.)

To convey his meaning still more fully, Leibnitz borrows from Mr Jaquelot¹ a comparison, which, whatever may be thought of its justness, must be at least allowed some merit in point of ingenuity. "Suppose that an intelligent and powerful being, who knew, beforehand, every particular thing that I should order my footman to do to-morrow, should make a machine to resemble my footman exactly, and punctually to perform, all day, whatever I directed. On this supposition, would not *my will*, in issuing all the details of my orders, remain, in every respect, in the same circumstances as before? And would not my machine-footman, in performing his different movements, have the appearance of acting only in obedience to my commands?" The inference to be drawn from this comparison is, that the movements of my body have no direct dependence whatever on the volitions of my mind, any more than the actions of my machine-footman would have on the words issuing from my lips. The same inference is to be extended to the relation which the *impressions* made on my different senses bear to the co-existent perceptions arising in my mind. The impressions and perceptions have no mutual *connection*, resembling that of physical causes with their effects; but the one series of events is made to correspond invariably with the other, in consequence of an eternal *harmony* between them, *pre-established* by their common Creator.

From this outline of the scheme of *Pre-established Harmony*, it is manifest, that it took its rise from the very same train of thinking which produced Malebranche's doctrine of *Occasional Causes*. The authors of both theories saw clearly the impossibility of tracing the mode in which mind acts on body, or body on mind; and hence were led rashly to conclude, that the *connection* or *union* which seems to exist between them is not real, but apparent. The inferences, however, which they drew from this common principle were directly opposite; Malebranche maintaining, that the communication between mind and body was carried on by the immediate and incessant agency of the Deity; while Leibnitz conceived, that the agency of God was employed only in the original contrivance and

¹ Author of a book entitled *Conformité de la Foi avec la Raison*.

mutual adjustment of the two machines;—all the subsequent phenomena of each, being the necessary result of its own independent mechanism, and, at the same time, the progressive evolutions of a comprehensive design, harmonizing the laws of the one with those of the other.

Of these two opposite hypotheses, that of Leibnitz is by far the more unphilosophical and untenable. The chief objection to the doctrine of *occasional causes* is, that it presumes to decide upon a question of which human reason is altogether incompetent to judge;—our ignorance of the mode in which matter acts upon mind, or mind upon matter, furnishing not the shadow of a proof that the one may not act directly and immediately on the other, in some way incomprehensible by our faculties.¹ But the doctrine of

¹ The mutual action (or, as it was called in the schools), the mutual *influence* (*influentia*) of soul and body, was, till the time of Descartes, the prevailing hypothesis, both among the learned and the vulgar. The reality of this *influentia*, if not positively denied by Descartes, was at least mentioned by him as a subject of doubt; but by Malebranche and Leibnitz it was confidently rejected as absurd and impossible. (See their works *passim*.) Gravesande, who had a very strong leaning towards the doctrines of Leibnitz, had yet the good sense to perceive the inconclusiveness of his reasoning in this particular instance, and states in opposition to it the following sound and decisive remarks: “Non concipio, quomodo mens in corpus agere possit; non etiam video, quomodo ex motu nervi perceptio sequatur; non tamen indè sequi mihi apparet, omnem *influxum* esse rejiciendum.

“Substantiæ incognitæ sunt. Jam vidimus naturam mentis nos latere; scimus hanc esse aliquid, quod ideas habet, has confert, &c. sed ignoramus quid sit subjectum, cui hæc proprietates convenient.

“Hoc idem de corpore dicimus; est extensum, impenetrabile, &c. sed quid est quod habet hæc proprietates? Nulla nobis via aperta est, quæ ad hanc cognitionem pervenire possimus.

“Indè concludimus, multa nos latere, quæ proprietates mentis et corporis spectant.

“Invicta demonstratione constat, non mentem in corpus, neque hoc in illam agere, ut corpus in corpus agit; sed mihi non videtur indè concludi posse, omnem *influxum* esse impossibilem.

“Motu suo corpus non agit in aliud corpus, sine resistente; sed an non actio, omnino diversa, et cujus ideam non habemus, in aliam substantiam dari possit, et ita tamen, ut causa effectui respondeat, in re adeò obscurâ, determinare non ausim. Difficile certè est *influxum* negare, quando exactè perpendimus, quomodò in minimis quæ mens percipit, relatio detur cum agitationibus in corpore, et quomodò hujus motus cum mentis determinationibus convenient. Attendo ad illa quæ medici, et anatomici, nos de his docent.

“Nihil, ergo, de systemate *influxus* determino, præter hoc, mihi mundum hujus impossibilitatem satis clarè demonstratam esse videri.”—(*Introducto ad Philosophiam*.) See Note (G.)

With respect to the *manner* in which the intercourse between Mind and Matter is carried on, a very rash assertion escaped Mr. Locke in the first edition of his *Essay*. “The next thing to be considered is, how bodies produce ideas in us, and that is manifestly by impulse, the only way which we can conceive bodies operate in.” (*Essay*, B. II. ch. viii. § 11.)

In the course of Locke's controversial discussions with the Bishop of Worcester, he afterwards became fully sensible of this important oversight; and he had the candour to acknowledge his error in the following terms: “’Tis true, I have said, that bodies operate by impulse, and nothing else. And so I thought when I writ it, and can yet conceive no other way of their operations. But I am since convinced, by the judicious Mr. Newton's incomparable book, that it is too bold a presumption to limit God's power in this

Pre-established Harmony, besides being equally liable to this objection, labours under the additional advantage of involving a perplexed and totally inconsistent conception of the nature of *Mechanism*;—an inconsistency, by the way, with which all those philosophers are justly chargeable, who imagine that, by likening the universe to a machine, they get rid of the necessity of admitting the constant agency of powers essentially different from the known qualities of matter. The word *Mechanism* properly expresses a combination of natural powers to produce a certain effect. When such a combination is successful, a machine, once set a going, will sometimes continue to perform its office for a considerable time, without requiring the interposition of the artist: And hence we are led to conclude, that the case may perhaps be similar with respect to the universe, when once put into motion by the Deity. This idea Leibnitz carried so far as to exclude the supposition of any subsequent agency in the first contriver and mover, excepting in the case of a miracle. But the falseness of the analogy appears from this, that the moving force in every machine is some *natural power*, such as gravity or elasticity; and, consequently, the very idea of mechanism assumes the existence of those active powers, of which it is the professed object of a mechanical theory of the universe to give an explanation. Whether, therefore, with Malebranche, we resolve every effect into the immediate agency of God, or suppose, with the great majority of Newtonians, that he employs the instrumentality of second causes to accomplish his purposes, we are equally forced to admit with Bacon, the necessity not only of a first contriver and mover, but of his constant and efficient concurrence (either immediately or mediately) in carrying his design into execution:—“*Opus* (says Bacon) *quod operatur Deus a primordio usque ad finem.*”

In what I have now said I have confined myself to the idea of *Mechanism* as it applies to the material universe; for, as to this word, when applied by Leibnitz to the mind, which he calls a *Spiritual Automaton*, I confess myself quite unable to annex a meaning to it: I shall not, therefore, offer any remarks on this part of his system.¹

point by my narrow conceptions. * * * * * And, therefore, in the next edition of my book, I will take care to have that passage rectified.”

It is a circumstance that can only be accounted for by the variety of Mr Locke's other pursuits, that in all the later editions of the *Essay* which have fallen in my way, the proposition in question has been allowed to remain as it originally stood.

¹ Absurd as the hypothesis of a *Pre-established Harmony* may now appear, not many years have elapsed since it was the prevailing, or rather universal creed, among the philosophers of Germany. “Il fut un temps” (says the celebrated Euler) “ou le système de l'harmonie pré-établie étoit tellement en vogue dans toute l'Allemagne, que ceux qui en doutoient, passoient pour des ignorans, ou des esprits bornés.” (*Lettres de M. Euler d'une Prince^{ne} d'Allemagne*, 83^e Lettre.) It would be amusing to reckon up the succession of metaphysical creeds which have been since swallowed with the same implicit faith by this learned and specula-

To these visionary speculations of Leibnitz, a strong and instructive contrast is exhibited in the philosophy of Locke; a philosophy, the main object of which is less to enlarge our knowledge, than to make us sensible of our ignorance; or (as the author himself expresses it) "to prevail with the busy mind of man to be cautious in meddling with things exceeding its comprehension; to stop when it is at the utmost extent of its tether; and to sit down in a quiet ignorance of those things, which, upon examination, are found to be beyond the reach of our capacities." "My right hand writes," says Locke, in another part of his *Essay*, "whilst my left hand is still. What causes rest in one, and motion in the other? Nothing but my will, a thought of my mind; my thought only changing, my right hand rests, and the left hand moves. *This is matter of fact which cannot be denied.* Explain this and make it intelligible, and then the next step will be to understand Creation. In the meantime, it is an overvaluing ourselves, to reduce all to the narrow measure of our capacities; and to conclude all things impossible to be done, whose manner of doing exceeds our comprehension. If you do not understand the operations of your own finite Mind, that thinking thing within you, do not deem it strange that you cannot comprehend the operations of that eternal infinite Mind, who made and governs all things, and whom the heaven of heavens cannot contain."¹ (Vol. II. pp. 249, 250.)

This contrast between the philosophical characters of Locke and of Leibnitz is the more deserving of notice, as something of the same sort has ever since continued to mark and to discriminate the metaphysical researches of the English and of the German schools. Various exceptions to this remark may, no doubt, be mentioned; but these exceptions will be found of trifling moment, when compared with the indisputable extent of its general application.

The theory of pre-established harmony led, by a natural and obvious transition, to the scheme of Optimism. As it represented all events, both in the physical and moral

tive, and (in all those branches of knowledge where imagination has no influence over the judgment) profound and inventive nation.

¹ That this is a fair representation of the scope of Locke's philosophy, according to the author's own view of it, is demonstrated by the two mottos prefixed to the *Essay on Human Understanding*. The one is a passage of the book of *Ecclesiastes*, which, from the place it occupies in the front of his work, may be presumed to express what he himself regarded as the most important moral to be drawn from his speculations. "As thou knowest not what is the way of the spirit, nor how the bones do grow in the womb of her that is with child; even so, thou knowest not the works of God, who maketh all things." The other motto (from Cicero) strongly expresses a sentiment which every competent judge must feel on comparing the above quotations from Locke, with the *monads* and the *pre-established harmony* of Leibnitz. "*Quam bellum est velle confiteri potius nescire quod nescias, quam ista effutientem nauseare, atque ipsum sibi displicere!*" See Note (H.)

worlds, as the necessary effects of a mechanism originally contrived and set a-going by the Deity, it reduced its author to the alternative of either calling in question the Divine power, wisdom, and goodness, or of asserting that the universe which he had called into being was the best of all possible systems. This last opinion, accordingly, was eagerly embraced by Leibnitz; and forms the subject of a work entitled *Theodicæa*, in which are combined together, in an extraordinary degree, the acuteness of the logician, the imagination of the poet, and the impenetrable, yet sublime darkness, of the metaphysical theologian.¹

The modification of Optimism, however, adopted by Leibnitz, was, in some essential respects, peculiar to himself. It differed from that of Plato, and of some other sages of antiquity, in considering the human mind in the light of a *spiritual machine*, and, of consequence, in positively denying the freedom of human actions. According to Plato, every thing is right, so far as it is the work of God;—the creation of beings endowed with free will, and consequently liable to moral delinquency;—and the government of the world by general laws, from which occasional evils *must* result;—furnishing no objection to the perfection of the universe, to which a satisfactory reply may not be found in the partial and narrow views of it, to which our faculties are at present confined. But he held at the same time, that, although the permission of moral evil does not detract from the goodness of God, it is nevertheless imputable to man as a fault, and renders him justly obnoxious to punishment. This system (under a variety of forms) has been in all ages maintained by the wisest and best philosophers, who, while they were anxious to vindicate the perfections of God, saw the importance of stating their doctrine in a manner not inconsistent with man's free will and moral agency.

The scheme of Optimism, on the contrary, as proposed by Leibnitz, is completely subversive of these cardinal truths. It was, indeed, viewed by the great and excellent author in a very different light; but in the judgment of the most impartial and profound inquirers, it leads, by a short and demonstrative process, to the annihilation of all moral distinctions.

¹ “La Théodicée seule (says Fontenelle) suffiroit pour représenter M. Leibnitz. Une lecture immense, des anecdotes curieuses sur les livres ou les personnes, beaucoup d'équité et même de faveur pour tous les auteurs cités, fut ce en les combattant; des vues sublimes et lumineuses, des raisonnemens au fond desquels on sent toujours, l'esprit géométrique, un style où la force domine, et où cependant sont admis les agrémens d'une imagination heureuse.”—*Eloge de Leibnitz*.

² It is observed by Dr Akenside, that “the Theory of Optimism has been delivered of late, especially abroad, in a manner which subverts the freedom of human actions; whereas Plato appears very careful to preserve it, and has been in that respect imitated by the best of his followers.” (Notes on the 2d Book of the *Pleasures of the Imagination*.)

It is of great importance to attend to the distinction between these two systems; because it has, of late, become customary among sceptical writers to confound them studiously together, in order to extend to both that ridicule to which the latter is justly entitled.

I am perfectly aware, at the same time, that different opinions have been entertained of Plato's real sentiments on this subject; and I readily grant that passages with respect to Fate and Necessity may be collected from his works, which it would be very difficult to reconcile with any one consistent scheme. (See the Notes of Mosheim on his Latin Version of Cudworth's *Intellectual System*, Tome I. pp. 10, 210, *et seq.* Lugd. Batav. 1773.)

Without entering at all into this question, I may be permitted here to avail myself, for the sake of conciseness, of Plato's name, to distinguish that modification of optimism which I have opposed in the text to the optimism of Leibnitz. The following sentence, in the 10th Book *De Republica*, seems sufficient of itself to authorise this liberty: Ἀρετὴ δ' ἀδίσπυτος, ἢ τιμῇ καὶ αἰτιμαζών, πλεον καὶ ἰσχυρὸς αὐτῆς ἔστι. αἰτία ἰσομεν. Θεὸς ἀναιτίος. *Virtus inviolabilis ac libera quam prout honerabit quis aut negliget, ita plus aut minus ex ea possidebit. Eligentis quidem culpa est omnis. Deus vero extra culpam.*

A short abstract of the allegory with which Leibnitz concludes his *Theodicaea*, will convey a clearer idea of the scope of that work, than I could hope to do by any metaphysical comment. The ground-work of this allegory is taken from a dialogue on Free-Will, written by Laurentius Valla, in opposition to Boethius;—in which dialogue, Sextus, the son of Tarquin the Proud, is introduced as consulting Apollo about his destiny. Apollo predicts to him that he is to violate Lucretia, and afterwards, with his family, to be expelled from Rome. (*Exul inopisque caedes iratus pulsus ab urbe.*) Sextus complains of the prediction. Apollo replies, that the fault is not his; that he has only the gift of seeing into futurity;* that all things are regulated by Jupiter; and that it is to him his complaint should be addressed. (*Here finishes the allegory of Valla, which Leibnitz thus continues, agreeably to his own principles.*) In consequence of the advice of the Oracle, Sextus goes to Dodona to complain to Jupiter of the crime which he is destined to perpetrate. “Why (says he) oh Jupiter! have you made me wicked and miserable? Either change my lot and my will, or admit that the fault is yours, not mine.” Jupiter replies to him: “Renounce all thoughts of Rome and of the crown; be wise and you shall be happy. If you return to Rome you are undone.” Sextus, unwilling to submit to such a sacrifice, quits the Temple, and abandons himself to his fate.

After his departure, the high Priest, Theodorus, asks Jupiter why he had not given another *Will* to Sextus. Jupiter sends Theodorus to Athens to consult Minerva. The goddess shows him the Palace of the Destinies, where are representations of all possible worlds,† each of them containing a Sextus Tarquinius with a different *Will*, leading to a catastrophe more or less happy. In the last and best of these worlds, forming the summit of the pyramid composed by the others, the high priest sees Sextus go to Rome, throw every thing into confusion, and violate the wife of his friend. “You see” (says the Goddess of Wisdom) “it was not my father that made Sextus wicked. He was wicked from all eternity, and he was always so in consequence of his own will.‡ Jupiter has only bestowed on him that existence which he could not refuse him in the best of all possible worlds. He only transferred him from the region of possible to that of actual beings. What great events does the crime of Sextus draw after it? The liberty of Rome—the rise of a government fertile in civil and military virtues, and of an empire destined to conquer and to civilize the earth.” Theodorus returns thanks to the goddess, and acknowledges the justice of Jupiter.

* “Futura novi, non facio.”

† *World* (it must be remembered) is here synonymous with *Universe*.

‡ “Vides Sextum a Patre meo non fuisse factum improbum, talis quippe ab omni aeternitate fuit, et quidem semper liber; existere tantum ei concessit Jupiter, quod ipsum profecto ejus sapientia mundo, in quo ille continebatur, denegare non poterat: egro Sextum e regione possibilitium ad rerum existentium classem transtulit.”

This, in particular, was the case with Voltaire, who, in many parts of his later works, and more especially in his *Candide*, has, under the pretence of exposing the extravagancies of Leibnitz, indulged his satirical raillery against the order of the universe. The success of his attempt was much aided by the confused and inaccurate manner in which the scheme of optimism had been recently stated by various writers, who, in their zeal to "vindicate the ways of God," had been led to hazard principles more dangerous in their consequences than the prejudices and errors which it was their aim to correct.¹

The zeal of Leibnitz in propagating the dogma of Necessity is not easily reconcileable with the hostility which (as I have already remarked) he uniformly displays against the congenial doctrine of Materialism. Such, however, is the fact, and I believe it to be quite unprecedented in the previous history of philosophy. Spinoza himself has not pushed the argument for necessity further than Leibnitz,—the reasonings of both concluding

¹ Among this number must be included the author of the *Essay on Man*, who, from a want of precision in his metaphysical ideas, has unconsciously fallen into various expressions, equally inconsistent with each other and with his own avowed opinions :

If plagues and earthquakes break not Heaven's design,
Why then a Borgia or a Catiline?—
Who knows but He whose hand the lightning forms,
Who heaves old Ocean, and who wings the storms,
Pours fierce ambition on a Caesar's mind,
Or turns young Ammon loose to scourge Mankind?—
* * * * *
—The general order, since the whole began,
Is kept in Nature, and is kept in Man.

This approaches very nearly to the optimism of Leibnitz, and has certainly nothing in common with the optimism of Plato. Nor is it possible to reconcile it with the sentiments inculcated by Pope in other parts of the same poem.

What makes all physical and moral ill?
There deviates Nature, and here wanders Will.

In this last couplet he seems to admit, not only that *Will* may *wander*, but that *Nature* herself may *deviate* from the *general order*; whereas the doctrine of his universal prayer is, that, while the material world is subjected to established laws, man is left to be the arbiter of his own destiny

Yet gav'at me in this dark estate
To know the good from ill,
And, binding Nature fast in fate,
Left free the human will.

In the *Dunciad*, too, the scheme of *Necessity* is coupled with that of *Materialism*, as one of the favourite doctrines of the sect of free-thinkers.

Of nought so certain as our Reason still,
Of nought so doubtful as of Soul and Will.

"Two things" (says Warburton, who professes to speak Pope's sentiments) "the most self-evident, the existence of our souls and the freedom of our will!"

not less forcibly against the free-will of God than against the free-will of man, and, of consequence, terminating ultimately in *this* proposition, that no event in the universe could possibly have been different from what has actually taken place.¹ The *distinguishing* feature of this article of the Leibnitzian creed is, that, while the Hobbists and Spinosists were employing their ingenuity in connecting together Materialism and Necessity, as branches springing from one common root, Leibnitz always speaks of the soul as a machine purely *spiritual*,²—a machine, however, as necessarily regulated by pre-ordained and immutable laws as the movements of a clock or the revolutions of the planets. In consequence of holding this language, he seemed to represent Man in a less degraded light than other necessitarians; but, in as far as such speculative tenets may be supposed to have any practical effect on human conduct, the tendency of his doctrines is not less dangerous than that of the most obnoxious systems avowed by his predecessors.³

The scheme of necessity was still farther adorned and sublimed in the *Theodicæa* of Leibnitz, by an imagination nurtured and trained in the school of Plato. “May there not exist” (he asks on one occasion) “an immense space beyond the region of the stars?”

¹ So completely, indeed, and so mathematically linked, did Leibnitz conceive all truths, both physical and moral, to be with each other, that he represents the eternal geometrician as incessantly occupied in the solution of this problem,—*The state of one Monad (or elementary atom) being given, to determine the state, past, present, and future, of the whole universe.*

² “Cuncta itaque in homine certa sunt, et in antecessum determinata, uti in cæteris rebus omnibus, et anima humana est *spirituale quoddam automatum.*” (Leib. Op. Tom. I. p. 156.)

In a note on this sentence, the editor quotes a passage from Bilfinger, a learned German, in which an attempt is made to vindicate the propriety of the phrase, by a reference to the etymology of the word *automaton*. This word, it is observed, when traced to its source, literally expresses something which contains within itself its principle of motion, and, consequently, it applies still more literally to *Mind* than to a machine. The remark, considered in a philological point of view, is indisputably just; but is it not evident, that it leads to a conclusion precisely contrary to what this author would deduce from it? Whatever may have been the primitive meaning of the word, its common, or rather its universal meaning, even among scientific writers, is a *material* machine, moving without any foreign impulse; and, that this was the idea annexed to it by Leibnitz, appears from his distinguishing it by the epithet *spirituale*,—an epithet which would have been altogether superfluous had he intended to convey the opinion ascribed to him by Bilfinger. In applying, therefore, this language to the mind, we may conclude, with confidence, that Leibnitz had no intention to contrast together mind and body, in respect of their moving or actuating principles, but only to contrast them in respect of the *substances* of which they are composed. In a word, he conceived both of them to be equally *machines*, made and wound up by the Supreme Being; but the machinery in the one case to be material, and in the other spiritual.

³ The following remark in Madame de Staël's interesting and eloquent review of German philosophy bears marks of a haste and precipitation with which her criticisms are seldom chargeable: “Les opinions de Leibnitz tendent surtout au perfectionnement moral, s'il est vrai, comme les philosophes Allemands ont tâché de le prouver, que le libre arbitre repose sur la doctrine qui affranchit l'âme des objets extérieures, et que la vertu ne puisse exister sans la parfaite indépendance du vouloir.”

and may not this *empyrean* heaven be filled with happiness and glory? It may be conceived to resemble an ocean, where the rivers of all those created beings that are destined for bliss shall finish their course, when arrived in the starry system, at the perfection of their respective natures." (Leib. *Op.* Tom. I. p. 135.)¹

In various other instances, he rises from the deep and seemingly hopeless abyss of *Fatalism*, to the same lofty conceptions of the universe; and has thus invested the most humiliating article of the atheistic creed, with an air of Platonic mysticism. The influence of his example appears to me to have contributed much to corrupt the taste and to bewilder the speculations of his countrymen; giving birth, in the last result, to that heterogeneous combination of all that is pernicious in Spinozism, with the transcendental eccentricities of a heated and exalted fancy, which, for many years past, has so deeply tinctured both their philosophy and their works of fiction.²

¹ The celebrated Charles Bonnet, in his work entitled *Contemplation de la Nature*, has indulged his imagination so far, in following out the above conjecture of Leibnitz, as to rival some of the wildest flights of Jacob Behmen. "Mais l'échelle de la création ne se termine point au plus élevés des mondes planétaires. Là commence un autre univers, dont l'étendue est peut-être à celle de l'univers des *Fées*, ce qu'est l'espace du système solaire à la capacité d'une noix.

"Là, comme des ASTRES resplendissans, brillent les HIERARCHIES CELESTES.

"Là rayonnent de toutes parts les ANGES, les ARCHANGES, les SERAPHINS, les CHIERUBINS, les TRONES, les VERTUS, les PRINCIPAUTES, les DOMINATIONs, les PUISSANCES.

"Au centre de ces AUGUSTES SPHERES, éclate le SOLEIL DE JUSTICE, l'ORIENT D'ENHAUT, dont tous les ASTRES empruntent leur lumière et leur splendeur."

"La *Theodicée* de Leibnitz" (the same author tells us in another passage) "est un de mes livres de devotion: J'ai intit. de mon Exemplaire, *Manuel de Philosophie Chrétienne*."

² "The gross appetite of Love (says Gibbon) becomes most dangerous when it is elevated, or rather disguised, by sentimental passion." The remark is strikingly applicable to some of the most popular novels and dramas of Germany; and something very similar to it will be found to hold with respect to those speculative extravagancies which, in the German systems of philosophy, are *elevated or disguised* by the imposing cant of moral enthusiasm.

In one of Leibnitz's controversial discussions with Dr Clarke, there is a passage which throws some light on his taste, not only in matters of science, but in judging of works of imagination. "Du temps de M. Boyle, et d'autres excellens hommes qui fleurissoient en Angleterre sous Charles II. on n'auroit pas osé nous débiter des notions *si creuses*. (The notions here alluded to are those of Newton concerning the law of gravitation.) J'espere que le *beautemps* reviendra sous un aussi bon gouvernement que celui d'à présent. Le capital de M. Boyle étoit d'inculquer que tout se faisoit *mechaniquement* dans la physique. Mais c'est un malheur des hommes, de se degouter enfin de la raison même, et de s'ennuyer de la lumière. Les chimères commence à revenir, et plaisent parce qu'elles sont quelque chose de merveilleux. Il arrive dans le pays philosophique ce qui est arrivé dans le pays poetique. On s'est lassé des Romans raisonnables, tel que la *Clélie Française* ou l'*Aramene Allemande*; et on est revenu depuis quelque temps aux *Contes des Fées*." (Cinquième Ecrit de M. Leibnitz, p. 266.)

From this passage it would seem, that Leibnitz looked forward to the period, when the dreams of the Newtonian philosophy would give way to some of the exploded mechanial theories of the universe; and

In other parts of Europe, the effects of the *Theodicæa* have not been equally unfavourable. In France, more particularly, it has furnished to the few who have cultivated with success the Philosophy of Mind, new weapons for combating the materialism of the Gassendists and Hobbists; and, in England, we are indebted to it for the irresistible reason-
s by which Clarke subverted the foundations on which the whole superstructure of Fa-
ism rests.¹

When the *Fairy-tales* then in fashion (among which number must have been included those of Count Anthony Hamilton) would be supplanted by the revival of such *reasonable Romances* as the *Grand Clelia*. In neither of these instances does there seem to be much probability at present, that his prediction will be ever verified.

The German writers, who, of late years, have made the greatest noise among the sciolists of this country, will be found less indebted for their fame to the new lights which they have struck out, than to the unexpected and grotesque forms in which they have combined together the materials supplied by the invention of former ages, and of other nations. It is this combination of truth and error in their philosophical systems, and of right and wrong in their works of fiction, which has enabled them to perplex the understandings, and to unsettle the principles of so many, both in Metaphysics and Ethics. In point of profound and extensive erudition, the scholars of Germany still continue to maintain their long established superiority over the rest of Europe.

A very interesting account is given by Leibnitz of the circumstances which gave occasion to his *Theodicæa*, in a letter to a Scotch Gentleman, Mr Burnet of Kemney; to whom he seems to have unbosomed himself on all subjects without any reserve. "Mon livre intitulé, *Essais de Theodicée*, sur la bonté de Dieu, la liberté de l'homme, et l'origine de mal, sera bientôt achevé. La plus grande partie de cet ouvrage avoit été faite par laimboux, quand je me trouvois chez la feue Reine de Prusse, où ces matières étoient souvent agitées à l'occasion du Dictionnaire et des autres ouvrages de M. Bayle qu'on y lisoit beaucoup. Après la mort de cette grande Princesse, j'ai rassemblé et augmenté ces pièces sur l'exhortation des amis qui en étoient informés, et j'en ai fait l'ouvrage dont je viens de parler. Comme j'ai médité sur cette matière depuis ma jeunesse je pretends de l'avoir discutée à fond." (Leibnitz, *Opera*, Tom VI. p. 284.)

In another letter to the same correspondent, he expresses himself thus:

"La plupart de mes sentimens ont été enfin arrêtés après une délibération de 20 ans: car j'ai commencé bien jeune à méditer, et je n'avois pas encore 15 ans, quand je me promenois des journées entières dans un bois, pour prendre parti entre Aristote et Democrite. Cependant j'ai changé et rechangé sur des nouvelles lumières, et ce n'est que depuis environ 12 ans que je me trouve satisfait, et que je suis arrivé à des démonstrations sur ces matières qui n'en paroissent point capables: Cependant de la manière que je m'y prends, ces démonstrations peuvent être sensibles comme celles des nombres, quoique le sujet passe l'imagination." (*Ibid.* p. 253.)

The letter from which this last paragraph is taken is dated in the year 1697.

My chief reason for introducing these extracts, was to do away an absurd suspicion, which has been countenanced by some respectable writers (among others by Le Clerc), that the opinions maintained in the *Theodicæa* of Leibnitz were not his real sentiments, and that his own creed, on the most important questions there discussed, was not very different from that of Bayle. Gibbon has even gone so far as to say, that "in his defence of the attributes and providence of the Deity, he was suspected of a secret correspondence with his adversary." (*Antiquities of the House of Brunswick*.) In support of this very improbable charge, I do not know that any evidence has ever been produced, but the following passage, in a letter of his addressed to a Professor of Theology in the University of Tubingen (Pfaffius): "Ita prorsus est, vir summe reverende, uti scribis, de Theo-

It may be justly regarded as a proof of the progress of reason and good sense among the Metaphysicians of this country since the time of Leibnitz, that the two theories of which I have been speaking, and which, not more than a century ago, were honoured by the opposition of such an antagonist as Clarke, are now remembered only as subjects of literary history.—In the arguments, however, alleged in support of these theories, there are some *logical* principles involved, which still continue to have an extensive influence over the reasonings of the learned, on questions seemingly the most remote from all metaphysical conclusions. The two most prominent of these are, the principle of the *Sufficient Reason*, and the *Law of Continuity*; both of them so intimately connected with some of the most celebrated disputes of the last century, as to require a more particular notice than may, at first sight, seem due to their importance.

I. Of the principle of the *Sufficient Reason*, the following succinct account is given by Leibnitz himself, in his controversial correspondence with Dr Clarke: “The great foundation of Mathematics is the principle of *contradiction* or *identity*; that is, that a proposition cannot be true and false at the same time. But, in order to proceed from Mathematics to Natural Philosophy, another principle is requisite (as I have observed in my *Theodicæa*); I mean the principle of the *Sufficient Reason*; or, in other words, that nothing happens without a *reason* why it should be so, rather than otherwise: And, accordingly, Archimedes was obliged, in his book *De Æquilibrio*, to take for granted, that if there be a balance, in which every thing is alike on both sides, and if equal weights are hung on the two ends of that balance, the whole will be at rest. It is because no *reason* can be given why one side should weigh down rather than the other. Now, by this single

dicæa mea. Rem acu tetigisti; et miror, neminem hactenus fuisse, qui sensum hunc meum senserit. Neque enim Philosophorum est rem serio semper agere; qui in fingendis hypothesibus, uti bene mones, ingenii sui vires experiuntur. Tu, qui Theologus, in refutandis erroribus Theologum agis.” In reply to this it is observed, by the learned editor of Leibnitz's works, that it is much more probable that Leibnitz should have expressed himself on this particular occasion in jocular and ironical terms, than that he should have wasted so much ingenuity and learning in support of an hypothesis to which he attached no faith whatever; an hypothesis (he might have added) with which the whole principles of his philosophy are systematically, and, as he conceived, mathematically connected. It is difficult to believe, that, among the innumerable correspondents of Leibnitz, he should have selected a Professor of Theology at Tubingen, as the sole depositary of a secret which he was anxious to conceal from all the rest of the world.

Surely a solitary document such as this weighs less than nothing, when opposed to the details quoted in the beginning of this note; not to mention its complete inconsistency with the character of Leibnitz, and with the whole tenor of his writings.

For my own part, I cannot help thinking, that the passage in question has far more the air of *persiflage* provoked by the vanity of Pfaffius, than of a serious compliment to his sagacity and penetration. No injunction to secrecy, it is to be observed, is here given by Leibnitz to his correspondent.

principle of the *Sufficient Reason*, may be demonstrated the being of a God, and all the other parts of Metaphysics or Natural Theology; and even, in some measure, those physical truths that are independent upon Mathematics, such as the Dynamical Principles, or the Principles of Forces."

Somes of the inferences deduced by Leibnitz from this almost gratuitous assumption are so paradoxical, that one cannot help wondering he was not a little staggered about its certainty. Not only was he led to conclude, that the mind is necessarily determined in all its elections by the influence of motives, insomuch that it would be impossible for it to make a choice between two things perfectly alike; but he had the boldness to extend this conclusion to the Deity, and to assert, that two things perfectly alike could not have been produced even by Divine Power. It was upon this ground that he rejected a *vacuum*, because all the parts of it would be perfectly alike to each other; and that he also rejected the supposition of *atoms*, or similar particles of matter, and ascribed to each particle a *monad*, or active principle, by which it is discriminated from every other particle.¹ The application of his principle, however, on which he evidently valued himself the most, was that to which I have already alluded the demonstrative evidence with which he conceived it to establish the impossibility of free-agency, not only in man, but in any other intelligent being;² a conclusion which, under whatever form of words it may be disguised, is liable to every objection which can be urged against the system of Spinoza.

With respect to the principle from which these important consequences were deduced, it is observable, that it is stated by Leibnitz in terms so general and vague, as to extend to all the different departments of our knowledge; for he tells us, that there must be a

¹ See Note (I.)

² The following comment on this part of the Leibnitzian system is from the pen of one of his greatest admirers, *Charles Bonnet*: " Cette Métaphysique transcendante deviendra un peu plus intelligible, si l'on fait attention, qu'en vertu du principe de la *raison suffisante*, tout est nécessairement lié dans l'univers. Toutes les Actions des Êtres Simples sont harmoniques, ou subordonnées les unes aux autres. L'exercice actuel de l'activité d'une monade donnée, est déterminé par l'exercice actuel de l'activité des monades aux-quelles elle correspond immédiatement. Cette correspondance continue d'un point quelconque de l'univers jusqu'à ses extrémités. Représentez-vous les ordres circulaires et concentriques qu'une pierre excite dans une eau dormante: Elles vont toujours en s'élargissant et en s'affaiblissant.

" Mais, l'état actuel d'une monade est nécessairement déterminé par son état antécédent: Celui-ci par un état qui a précédé, et ainsi en remontant jusqu'à l'instant de la création.

" Ainsi le passé, le présent, et le futur ne forment dans la même monade qu'une seule chaîne. Notre philosophe disoit ingénieusement que *le présent est toujours gros de l'avenir*.

" Il disoit encore que l'Eternel Géomètre résolvoit sans cesse ce Problème; l'état d'une monade étant donné, en déterminer l'état passé présent, et futur de tout l'univers." (*Bonnet*, Tom. VIII. p. 303, 304, 305.)

sufficient reason for every *existence*, for every *event*, and for every *truth*. This use of the word *reason* is so extremely equivocal, that it is quite impossible to annex any precise idea to the proposition. Of this it is unnecessary to produce any other proof than the application which is here made of it to things so very different as *existences*, *events*, and *truths*; in all of which cases, it must of necessity have different meanings. It would be a vain attempt, therefore, to combat the maxim in the form in which it is commonly appealed to: Nor, indeed, can we either adopt or reject it, without considering particularly how far it holds in the various instances to which it may be applied.

The multifarious discussions, however, of a physical, a metaphysical, and a theological nature,¹ necessarily involved in so detailed an examination, would, in the present times (even if this were a proper place for introducing them), be equally useless and uninteresting; the peculiar opinions of Leibnitz on most questions connected with these sciences having already fallen into complete neglect. But as the maxim still continues to be quoted by the latest advocates for the scheme of necessity, it may not be altogether superfluous to observe, that, when understood to refer to the changes that take place in the *material* universe, it coincides entirely with the common maxim, that “every change implies the operation of a *cause*;” and that it is in consequence of its intuitive evidence in this particular case, that so many have been led to acquiesce in it, in the unlimited terms in which Leibnitz has announced it. One thing will be readily granted, that the maxim, when applied to the determinations of intelligent and moral *agents*, is not *quite* so obvious and indisputable, as when applied to the changes that take place in things altogether inanimate and passive.

What then, it may be asked, induced Leibnitz, in the enunciation of his maxim, to depart from the form in which it has generally been stated, and to substitute, instead of the word *cause*, the word *reason*, which is certainly not only the more unusual, but the more ambiguous expression of the two? Was it not evidently, a perception of the impropriety of calling the motives from which we act the *causes* of our actions; or, at least of the inconsistency of this language with the common ideas and feelings of mankind? The word *rea-*

¹ Since the time of Leibnitz, the principle of the *sufficient reason* has been adopted by some mathematicians as a legitimate mode of reason: 3 in plane geometry; in which case, the application made of it has been, in general, just and logical, notwithstanding the vague and loose manner in which it is expressed. In this science, however, the use of it can never be attended with much advantage; except perhaps in demonstrating a few elementary truths (such as the 5th and 6th propositions of Euclid's first book), which are commonly established by a more circuitous process: And, even in these instances, the spirit of the reasoning might easily be preserved under a different form, much less exceptionable in point of phraseology.

son is *here* much less suspicious, and much more likely to pass current without examination. It was therefore with no small dexterity, that Leibnitz contrived to express his general principle in such a manner, that the impropriety of his language should be most apparent in that case in which the proposition is instantaneously admitted by every reader as self-evident; and to adapt it, in its most precise and definite shape, to the case in which it was in the greatest danger of undergoing a severe scrutiny. In this respect, he has managed his argument with more address than Collins, or Edwards, or Hume, all of whom have applied the maxim to *mind*, in the very same words in which it is usually applied to inanimate matter.

But on this article of Leibnitz's philosophy, which gave occasion to his celebrated controversy with Clarke, I shall have a more convenient opportunity to offer some strictures when I come to take notice of another antagonist, more formidable still, whom Clarke had soon after to contend with on the same ground. The person I allude to is Anthony Collins; a writer certainly not once to be compared with Leibnitz, in the grasp of his intellectual powers; but who seems to have studied this particular question with greater attention and accuracy, and who is universally allowed to have defended his opinions concerning it in a manner far more likely to mislead the opinions of the multitude.

II. The same remark which has been already made on the principle of the *Sufficient Reason* may be extended to that of the *Law of Continuity*. In both instances the phraseology is so indeterminate, that it may be interpreted in various senses essentially different from each other; and, accordingly, it would be idle to argue against either principle as a general theorem, without attending separately to the specialties of the manifold cases which it may be understood to comprehend. Where such a latitude is taken in the enunciation of a proposition, which, so far as it is true, must have been inferred from an induction of particulars, it is at least possible that, while it holds in *some* of its applications, it may yet be far from possessing any claim to that universality which seems necessarily to belong to it, when considered in the light of a metaphysical axiom, resting on its own intrinsic evidence.

Whether this vagueness of language was the effect of artifice, or of a real vagueness in the author's notions, may perhaps be doubted; but that it has contributed greatly to extend his reputation among a very numerous class of readers, may be confidently asserted. The possession of a general maxim, sanctioned by the authority of an illustrious name, and in which, as in those of the schoolmen, *more seems to be meant than meets the ear*, affords of itself no slight gratification to the vanity of many; nor is it inconvenient for a disputant, that the maxims to which he is to appeal should be stated in so dubious a shape, as to en-

able him, when pressed in an argument, to shift his ground at pleasure, from one interpretation to another. The extraordinary popularity which, in our own times, the philosophy of Kant enjoyed, for a few years, among the countrymen of Leibnitz, may, in like manner, be in a great degree ascribed to the imposing aspect of his enigmatical oracles, and to the consequent facility of arguing without end, in defence of a system to transmutable and so elusive in its forms.

The extension, however, given to the *Law of Continuity*, in the later publications of Leibnitz, and still more by some of his successors, has been far greater than there is any reason to think was originally in the author's contemplation. It first occurred to him in the course of one of his physical controversies, and was probably suggested by the beautiful exemplifications of it which occur in pure geometry. At that time it does not appear that he had the slightest idea of its being susceptible of any application to the objects of natural history; far less to the succession of events in the intellectual and moral worlds. The supposition of bodies *perfectly hard*, having been shown to be inconsistent with two of his leading doctrines, *that* of the constant maintenance of the same quantity of force in the Universe, and *that* of the proportionality of forces to the squares of the velocities,—he found himself reduced to the necessity of asserting, that all changes are produced by insensible gradations, so as to render it impossible for a body to have its state changed from motion to rest, or from rest to motion, without passing through all the intermediate states of velocity. From this assumption he argued, with much ingenuity, that the existence of atoms, or of perfectly hard bodies, is impossible; because, if two of them should meet with equal and opposite motions, they would necessarily stop at once, in violation of the *law of continuity*. It would, perhaps, have been still more logical, had he argued against the universality of a law so gratuitously assumed, from its incompatibility with an hypothesis, which, whether true or false, certainly involves nothing either contradictory or improbable: but as this inversion of the argument would have undermined some of the fundamental principles of his physical system, he chose rather to adopt the other alternative, and to announce the *law of continuity* as a metaphysical truth, which admitted of no exception whatever. The facility with which this *law* has been adopted by subsequent philosophers is not easily explicable; more especially, as it has been maintained by many who reject those physical errors, in defence of which Leibnitz was first led to advance it.

One of the earliest, and certainly the most illustrious, of all the partizans and defenders of this principle, was John Bernouilli, whose discourse on motion first appeared at Paris in 1727, having been previously communicated to the Royal Academy of Sciences, in

1724 and 1726.¹ It was from this period it began to attract the general attention of the learned; although many years were yet to elapse, before it was to acquire that authority which it now possesses among our most eminent mathematicians.

Mr Maclaurin, whose Memoir on the *Percussion of Bodies* gained the prize from the Royal Academy of Sciences, in 1724, continued from that time, till his death, the steady opposer of this new law. In his treatise of *Fluxions*, published in 1742, he observes, that “the existence of hard bodies void of elasticity has been rejected for the sake of what is called the *Law of Continuity*; a law which has been supposed to be general, without sufficient ground.”² And still more explicitly, in his *Posthumous Account of Newton's Philosophical Discoveries*, he complains of those who “have rejected hard bodies as impossible, from far-fetched and metaphysical considerations;” proposing to his adversaries this unanswerable question, “Upon what grounds is the *law of continuity* assumed as an universal law of nature?”³

“En effet (says Bernouilli), un pareil principe de dureté (the supposition to wit of bodies perfectly hard) ne sauroit exister; c'est une chimere qui répugne à cette loi générale que la nature observe constamment dans toutes ses opérations; je parle de cet ordre immuable et perpétuel établi depuis la création de l'univers, qu'on peut appeler LOI DE CONTINUITÉ en vertu de laquelle tout ce qui s'exécute, s'exécute par des degrés infiniment petits. Il semble que le bon sens dicte, qu'aucun changement ne peut se faire par saut; *natura non operatur per saltum*; rien ne peut passer d'une extrémité à l'autre, sans passer par tous les degrés du milieu,” &c. The continuation of this passage (which I have not room to quote) is curious, as it suggests an argument, in proof of the *law of continuity*, from the principle of the *sufficient reason*.

It may be worth while to observe here, that though, in the above quotation, Bernouilli speaks of the *law of continuity* as an arbitrary arrangement of the Creator, he represents in the preceding paragraph, the idea of perfectly hard bodies, as involving a manifest contradiction.

² Maclaurin's *Fluxions*, Vol. II. p. 438.

³ Nearly to the same purpose Mr Robins, a mathematician and philosopher of the highest eminence, expresses himself thus: “M. Bernouilli (in his *Discours sur les Lois de la Communication du Mouvement*), in order to prove that there are no bodies perfectly hard and inflexible, lays it down as an immutable law of nature, that no body can pass from motion to rest instantaneously, or without having its velocity gradually diminished. That this is a law of nature, M. Bernouilli thinks is evident from that principle, *Natura non operatur per saltum*, and from good sense. BUT HOW GOOD SENSE CAN, OF ITSELF, WITHOUT EXPERIMENT, DETERMINE ANY OF THE LAWS OF NATURE, IS TO ME VERY ASTONISHING. Indeed, from any thing M. Bernouilli has said, it would have been altogether as conclusive to have begun at the other end, and have disputed, that no body can pass instantaneously from motion to rest; because it is an immutable law of nature that all bodies shall be flexible.” (Robins, Vol. II. p. 171, 175.)

In quoting these passages, I would not wish to be understood as calling in question the universality of the *Law of Continuity* in the phenomena of moving bodies; a point on which I am not led by the subject of this discourse to offer any opinion, but on which I intend to hazard some remarks in a Note at the end of it. See Note (K) All that I would here assert is, that it is a *law* the truth of which can be inferred only by an induction from the phenomena; and to which, accordingly, we are not entitled to say that there cannot possibly exist any exceptions.

In the speculations hitherto mentioned, the *law of continuity* is applied merely to such *successive* events in the material world as are connected together by the relation of *cause and effect*; and, indeed, *chiefly* to the changes which take place in the state of bodies with respect to *motion and rest*. But in the philosophy of Leibnitz, we find the same *law* appealed to as an indisputable principle in all its various researches, physical, metaphysical, and theological. He extends it with the same confidence to mind as to matter, urging it as a demonstrative proof, in opposition to Locke, that the soul never ceases to think even in sleep or in a *deliquium*;¹ nay, inferring from it the impossibility that, in the case of any animated being, there should be such a thing as *death* in the literal sense of that word.² It is by no means probable that the author was at all aware, when he first introduced this principle into the theory of motion, how far it was to lead him in his researches concerning other questions of greater moment; nor does it appear that it attracted much notice from the learned, but as a new *mechanical* axiom, till a considerable time after his death.

Charles Bonnet of Geneva, a man of unquestionable talents and of most exemplary worth, was, as far as I know, the first who entered fully into the views of Leibnitz on this point; perceiving how inseparably the law of continuity (as well as the principle of the sufficient reason) was interwoven with his scheme of universal concatenation and mechanism; and inferring from thence not only all the paradoxical corollaries deduced from it by its author, but some equally bold conclusions of his own, which Leibnitz either did not foresee in their full extent, or to which the course of his inquiries did not particularly attract his attention. The most remarkable of these conclusions was, that all the various beings which compose the universe, form a scale descending downwards without any chasm or *saltus*, from the Deity to the simplest forms of unorganised matter; a proposi-

¹ " Je tiens que l'âme, et même le corps, n'est jamais sans action, et que l'âme n'est jamais sans quelque perception, même en dormant, on a quelque sentiment confus et sombre du lieu où l'on est, et d'autres choses. Mais quand l'expérience ne le confirmeroit pas, je crois qu'il y en a démonstration. C'est à peu près comme on ne pourroit prouver absolument par les expériences, s'il n'y a point de vuide dans l'espace, et s'il n'y a point de repos dans la matière. Et cependant ces questions me paroissent décidées démonstrativement aussi bien qu'à M. Locke." (Leib. Op. Tome II. p. 220.)

² See Note (L.)

³ " Leibnitz admettoit comme un principe fondamental de sa sublime philosophie, qu'il n'y a jamais de sauts dans la nature, et que tout est continu ou nuance dans le physique et dans le moral. C'étoit sa fameuse *Loi de Continuité*, qu'il croyoit retrouver encore dans les mathématiques, et c'étoit cette loi qui lui avoit inspiré la singulière prédiction dont je parlois." " Tous les êtres, disoit il, ne forment qu'une seule chaîne, dans laquelle les différentes classes, comme autant d'anneaux, tiennent si étroitement les unes aux autres, qu'il est impossible aux sens et à l'imagination de fixer précisément le point où quelqu'une com-

* La prédiction de la découverte des Polypes.

tion not altogether new in the history of philosophy, but which I do not know that any writer before Bonnet had ventured to assert as a metaphysical and necessary truth. With what important limitations and exceptions it must be received, even when confined to the comparative anatomy of animals, has been fully demonstrated by Cuvier; and it is of material consequence to remark, that these exceptions, how few soever, to a metaphysical principle, are not less fatal to its truth than if they exceeded in number the instances which are quoted in support of the general rule.²

At a period somewhat later, an attempt has been made to connect the *same law of continuity* with the history of human improvement, and more particularly with the progress of invention in the sciences and arts. Helvetius is the most noted writer in whom I have observed this last extension of the Leibnitzian principle; and I have little doubt, from his

commence ou finit: toutes les especes qui bordent ou qui occupent, pour ainsi dire, les régions d'inflexion, et de rebroussement, doivent être équivoques et douces de caractères qui peuvent se rapporter aux espèces voisins également. Ainsi, l'existence des zoophytes ou *Plant-Animaux* n'a rien de monstrueux; mais il est même convenable

l'ordre de la nature qu'il y en ait. Et telle est la force du principe de continuité chez moi, que non seulement je ne serois point étonné d'apprendre, qu'on eut trouvé des êtres, qui par rapport à plusieurs propriétés, par exemple, celle de se nourrir ou de se multiplier, puissent passer pour des végétaux à aussi bon droit que pour des animaux, . . . J'en serois si peu étonné dis-je, que même je suis convaincu qu'il doit y en avoir de tels. que l'Histoire Naturelle parviendra peut-être à connoître un jour," &c. &c. (*Contemplation de la Nature*. pp. 341, 342.)

Bonnet, in the sequel of this passage, speaks of the words of Leibnitz, as a prediction of the discovery of the *Polypus*, deduced from the *Metaphysical principle of the Law of Continuity*. But would it not be more philosophical to regard it as a query founded on the *analogy of nature*, as made known to us by experience and observation?

¹ *Leçons d'Anatomie Comparée*.

While Bonnet was thus employing his ingenuity in generalizing, still farther than his predecessors had done, the law of continuity, one of the most distinguished of his fellow citizens, with whom he appears to have been connected in the closest and most confidential friendship (the very ingenious M. Le Sage), was led, in the course of his researches concerning the physical cause of gravitation, to deny the existence of the law, even in the descent of heavy bodies. "The action of gravity (according to him) is *not* continuous." In other words, "each of its impressions is finite; and the interval of time which separates it from the following impression is of a finite duration." Of this proposition he offers a proof, which he considers as demonstrative; and thence deduces the following very paradoxical corollary, That "Projectiles do not move in curvilinear paths, but in rectilinear polygons."—"C'est ainsi (he adds) qu'un prés, qui vû de près, se trouve couvert de parties vertes réellement séparées, offre cependant aux personnes qui le regardent de loin, la sensation d'une verdure continuë: Et qu'un corps poli, auquel le microscope deconvre mille solutions de continuité, paroit à l'œil nu, posséder une continuité parfaite."

"Généralement, le simple bon sens, qui veut, qu'on suspende son jugement sur ce qu'on ignore, et que l'on ne tranche pas hardiment sur la non-existence de ce qui échappe à nos sens, auroit dû empêcher des gens qui s'appeloient philosophes de décider si dogmatiquement, la continuité réelle, de ce qui avoit une continuité apparente; et la non-existence des intervalles qu'ils n'apercevoient pas." (*Essai de Chymie Mécanique*. Couronné en 1758, par l'Académie de Rouen; Imprime à Geneve, 1761. pp. 94, 95, 96.)

known opinions, that, when it occurred to him, he conceived it to afford a new illustration of the scheme of necessity, and of the mechanical concatenation of all the phenomena of human life. Arguing in support of his favourite paradox concerning the original equality of all men in point of mental capacity, he represents the successive advances made by different individuals in the career of discovery, as so many imperceptible or infinitesimal steps, each individual surpassing his predecessor by a trifle, till at length nothing is wanting but an additional mind (not superior to the others in natural powers) to combine together, and to turn to its own account, their accumulated labours. "It is upon *this* mind," he observes, "that the world is always ready to bestow the attribute of genius. From the tragedies of *The Passion*, to the poet Hardy and Rotrou, and to the *Mariamne* of Tristram, the French theatre was always acquiring successively an infinite number of inconsiderable improvements. Corneille was born at a moment, when the addition he made to the art could not fail to form an epoch; and accordingly Corneille is universally regarded as a Genius. I am far from wishing," Helvetius adds, "to detract from the glory of this great poet. I wish only to prove, that *Nature never proceeds PER SALTUM, and that the Law of Continuity is always exactly observed.* The remarks, therefore, now made on the dramatic art, may also be applied to the sciences which rest on observation."¹ (*De l'Esprit*, Dis. IV. Chap. 1.)

With this last extension of the *Law of Continuity*, as well as with that of Bonnet, a careless reader is the more apt to be dazzled, as there is a large mixture in both of unquestionable truth. The mistake of the ingenious writers lay in pushing to *extreme cases* a doctrine, which, when kept within certain limits, is not only solid but important; a mode of reasoning, which, although it may be always safely followed out in pure Mathematics (where the principles on which we proceed are mere definitions), is a never-failing source

¹ It may, perhaps, be alleged, that the above allusion to the *Law of Continuity* was introduced merely for the sake of illustration, and that the author did not mean his words to be strictly interpreted; but this remark will not be made by those who are acquainted with the philosophy of Helvetius.

Let me add, that, in selecting Corneille as the only exemplification of this theory, Helvetius has been singularly unfortunate. It would have been difficult to have named any other modern poet, in whose works, when compared with those of his immediate predecessors, the *Law of Continuity* has been more remarkably violated. "Corneille (says a most judicious French critic) est, pour ainsi dire, de notre tems; mais ses contemporains n'en sont pas. *Le Cid*, les *Horaces*, *Cinna*, *Polixene*, forment le commencement de cette chaîne brillante qui réunit notre littérature actuelle de celle du règne de Richelieu et de la minorité de Louis XIV.; mais autour de ces points lumineux règne encore une nuit profonde; leur éclat les rapproche en apparence de nos yeux; le reste, repoussé dans l'obscurité, semble bien loin de nous. Pour nous Corneille est moderne, et Rotrou ancien," &c. (For detailed illustrations and proofs of these positions, see a slight but masterly historical sketch of the French Theatre, by M. Suard.)

of error in all the other sciences; and which, when practically applied to the concerns of life, may be regarded as an infallible symptom of an understanding better fitted for the subtle contentions of the schools, than for those average estimates of what is expedient and practicable in the conduct of affairs, which form the chief elements of political sagacity and of moral wisdom.¹

If on these two celebrated principles of Leibnitz, I have enlarged at greater length than may appear to some of my readers to be necessary, I must remind them, 1st, Of the illustration they afford of what Locke has so forcibly urged with respect to the danger of adopting, upon the faith of reasonings *a priori*, metaphysical conclusions concerning the laws by which the universe is governed: 2dly, Of the proof they exhibit of the strong bias of the human mind, even in the present advanced stage of experimental knowledge, to grasp at general maxims, without a careful examination of the grounds on which they rest; and of that less frequent, but not less unfortunate bias, which has led some of our most eminent mathematicians to transfer to sciences, resting ultimately on an appeal to facts, those habits of thinking which have been formed amidst the hypothetical abstractions of pure geometry: Lastly, Of the light they throw on the mighty influence which the name and authority of Leibnitz has, for more than a century past, exercised over the strongest and acutest understandings in the most enlightened countries of Europe.

It would be improper to close these reflections on the philosophical speculations of Leibnitz, without taking some notice of his very ingenious and original thoughts on the etymological study of languages, considered as a guide to our conclusions concerning the origin and migrations of different tribes of our species. These thoughts were published in 1710, in the *Memoirs* of the Berlin Academy; and from the first article of the first

¹ Locke has fallen into a train of thought very similar to that of Bonnet, concerning the *Scale of Beings*; but has expressed himself with far greater caution;—stating it modestly as an inference deduced from an induction of particulars, not as the result of any abstract or metaphysical principle. (See *Locke's Works*, Vol. III. p. 101.) In one instance, indeed, he avails himself of an allusion, which, at first sight, may appear to favour the extension of the mathematical *Law of Continuity* to the works of creation; but it is evident, from the context, that he means this allusion merely as a popular illustration of a fact in Natural History; not as the rigorous enunciation of a theorem applicable alike to all truths, mathematical, physical, and moral. “It is a hard matter to say where sensible and rational begin, and where insensible and irrational end; and who is there quick-sighted enough to determine precisely, which is the lowest species of living things, and which is the first of those who have no life? Things, as far as we can observe, lessen and augment, as the quantity does in a *regular cone*, where, though there be a manifest odds betwixt the bigness of the diameter at a remote distance, yet the difference between the upper and under, where they touch one another, is hardly discernible.” (*Ibid.*)

See some Reflections on this speculation of Locke's in the *Spectator*, No. 519.

volume of that justly celebrated collection. I do not recollect any author of an earlier date, who seems to have been completely aware of the important consequences to which the prosecution of this inquiry is likely to lead; nor, indeed, was much progress made in it by any of Leibnitz's successors, till towards the end of the last century; when it became a favourite object of pursuit to some very learned and ingenious men, both in France, Germany, and England. Now, however, when our knowledge of the globe, and of its inhabitants, is so wonderfully enlarged by commerce, and by conquest; and when so great advances have been made in the acquisition of languages, the names of which, till very lately, were unheard of in this quarter of the world;—there is every reason to hope for a series of farther discoveries, strengthening progressively, by the multiplication of their mutual points of contact, the common evidence of their joint results; and tending more and more to dissipate the darkness in which the primeval history of our race is involved. It is a field, of which only detached corners have hitherto been explored; and in which, it may be confidently presumed, that unthought of treasures still lie hid, to reward sooner or later the researches of our posterity.¹

My present subject does not lead me to speak of the mathematical and physical researches, which have associated so closely the name of Leibnitz with that of Newton, in the history of modern science; of the inexhaustible treasures of his erudition, both classical and scholastic; of his vast and manifold contributions towards the elucidation of German antiquities and of Roman jurisprudence; or of those theological controversies, in which, while he combated with one hand the enemies of revelation, he defended, with the other, the orthodoxy of his own dogmas against the profoundest and most learned divines of Europe. Nor would I have digressed so far as to allude here to these particulars, were it not for the unparalleled example they display, of what a vigorous and versatile genius, seconded by habits of persevering industry, may accomplish, within the short span of human life. Even the relaxations with which he was accustomed to fill up his moments of leisure, partook of the general character of his more serious engagements. By early and long habit, he had acquired a singular facility in the composition of Latin verses; and he seems to have delighted in loading his muse with new fetters of his own contrivance, in addition to those imposed by the laws of classical prosody.² The number, besides, of his literary correspondents

¹ See Note (M.)

² A remarkable instance of this is mentioned by himself in one of his letters. “*Annos natus tredecim una die trecentos versus hexametros effudi, sine elisione omnes, quod hoc fieri facile posse fortè affirmassem.*” (Leib. *Op.* Tom. V. p. 304.) He also amused himself occasionally with writing verses in German and in French.

was immense; including all that was most illustrious in Europe: and the rich materials everywhere scattered over his letters are sufficient of themselves to show, that his amusements consisted rather in a change of objects, than in a suspension of his mental activity. Yet while we admire these stupendous monuments of his intellectual energy, we must not forget (if I may borrow the language of Gibbon) that “even the powers of Leibnitz were dissipated by the multiplicity of his pursuits. He attempted more than he could finish; he designed more than he could execute; his imagination was too easily satisfied with a bold and rapid glance on the subject which he was impatient to leave; and he may be compared to those heroes whose empire has been lost in the ambition of universal conquest.”¹

From some expressions which Leibnitz has occasionally dropped, I think it probable, that he himself became sensible, as he advanced in life, that his time might have been more profitably employed, had his studies been more confined in their aim. “If the whole earth (he has observed on one occasion) had continued to be of one language and of one speech, human life might be considered as extended beyond its present term, by the addition of all that part of it which is devoted to the acquisition of dead and foreign tongues. Many other branches of knowledge, too, may, in this respect, be classed with the languages; such as Positive Laws, Ceremonies, the Styles of Courts, and a great proportion of what is called *critical erudition*. The utility of all these arises merely from opinion; nor is there to be found, in the innumerable volumes that have been written to illustrate them, a hundredth part, which contains anything subservient to the happiness or improvement of mankind.”

The most instructive lesson, however, to be drawn from the history of Leibnitz, is the incompetency of the most splendid gifts of the understanding, to advance essentially the interests either of metaphysical or of Ethical Science, unless accompanied with that rare devotion to truth, which may be regarded, if not as the basis, at least as one of the most indispensable elements, of moral genius. The chief attraction to the study of philosophy, in *his mind*, seems to have been (what many French critics have considered as a chief source of the charms of the imitative arts) the pride of *conquering difficulties*: a feature of his character which he had probably in his own eye, when he remarked (not without some degree of conscious vanity), as a peculiarity in the turn or cast of his intellect, that to *him* “all difficult

¹ May I presume to remark farther, that the native powers of Leibnitz's mind, astonishing and preternatural as they certainly were, seem sometimes oppressed and overlaid under the weight of his still more astonishing erudition? The influence of his scholastic reading is more peculiarly apparent in warping his judgment, and clouding his reason, on all questions connected with Metaphysical Theology.

things were easy, and all easy things difficult.”¹ Hence the disregard manifested in his writings to the simple and obvious conclusions of experience and common sense; and the perpetual effort to unriddle mysteries over which an impenetrable veil is drawn. “*Scilicet sublime et erectum ingenium pulchritudinem ac speciem excelsæ magnæque gloriæ vehementius quam caute appetebat.*” It is to be regretted that the sequel of this fine eulogy does not equally apply to him. “*Mox mitigavit ratio et ætas; retinuitque, quod est difficillimum, et in sapientia modum.*”² How happily does this last expression characterize the temperate wisdom of Locke, when contrasted with that towering, but impotent ambition, which, in the Theories of Optimism and of Pre-established Harmony, seemed to realize the fabled revolt of the giants against the sovereignty of the gods!

After all, a similarity may be traced between these two great men in *one* intellectual weakness common to both; a facility in the admission of facts, stamped sufficiently (as we should *now* think) by their own intrinsic evidence, with the marks of incredibility. The observation has been often made with respect to Locke; but it would be difficult to find in Locke’s writings, any thing so absurd as an account gravely transmitted by Leibnitz to the Abbé de St Pierre, and by him communicated to the Royal Academy of Sciences at Paris, of a dog who spoke.³ No person liberally educated could, I believe, be found at present in any *Protestant* country of Christendom, capable of such credulity. By what causes so extraordinary a revolution in the minds of men has been effected, within the short space of a hundred years, I must not here stop to inquire. Much, I apprehend, must be ascribed to our enlarged knowledge of nature, and more particularly to those scientific voyages and travels which have annihilated so many of the prodigies which exercised the wonder and subdued the reason of our ancestors. But, in whatever manner the revolution is to be explained, there can be no doubt that this growing disposition to weigh scrupulously the *probability* of alleged *facts* against the faith due to the testimonies brought to attest them, and, even in some cases, against the apparent evidence of our own senses, enters largely and essentially into the composition of that philosophical *spirit* or temper, which so strongly distinguishes the eighteenth century from all those which preceded it.⁴ It is no small consolation to reflect, that some important maxims of good sense have been thus familiarized to the most ordinary understandings, which, at so very recent a period, failed in producing their due effect on two of the most powerful minds in Europe.

¹ “*Sentio paucos esse mei characteris, et omnia facilia mihi difficilia, omnia contra difficilia mihi facilia esse.*” —Leib. *Op.* Tom. VI. p. 302.

² Tacitus, *Agric.*

³ See Note (N.)

⁴ See Note (O.)

On reviewing the foregoing paragraphs, I am almost tempted to retract part of what I have written, when I reflect on the benefits which the world has derived even from the *errors* of Leibnitz. It has been well and justly said, "that every *desideratum* is an imperfect discovery;" to which it may be added, that every new problem which is started, and still more every attempt, however abortive, towards its solution, strikes out a new path, which must sooner or later lead to the truth. If the problem be solvable, a solution will in due time be obtained: If insoluble, it will soon be abandoned as hopeless by general consent; and the legitimate field of scientific research will become more fertile, in proportion as a more accurate survey of its boundaries adapts it better to the limited resources of the cultivators.

In this point of view, what individual in modern times can be compared to Leibnitz! To how many of those researches, which still usefully employ the talents and industry of the learned, did he not point out and open the way! From how many more did he not warn the wise to withhold their curiosity, by his bold and fruitless attempts to burst the barriers of the invisible world!

The best *éloge* of Leibnitz is furnished by the literary history of the eighteenth century;—a history which, whoever takes the pains to compare with his works, and with his epistolary correspondence, will find reason to doubt whether, at the singular era when he appeared, he could have more accelerated the advancement of knowledge by the concentration of his studies, than he has actually done by the universality of his aims; and whether he does not afford one of the few instances to which the words of the poet may literally be applied:

"Si non errasset, fecerat ille minus."¹

SECTION III.

Of the Metaphysical Speculations of Newton and Clarke.—Digression with respect to the System of Spinoza.—Collins and Jonathan Edwards.—Anxiety of both to reconcile the Scheme of Necessity with Man's Moral Agency.—Departure of some later Necessitarians from their views.²

THE foregoing review of the philosophical writings of Locke and of Leibnitz naturally leads our attention, in the next place, to those of our illustrious countrymen Newton and

¹ See Note (P.)

² In conformity to the plan announced in the preface to this *Dissertation*, I confine myself to those authors whose opinions have had a marked and general influence on the subsequent history of philosophy;

Clarke; the former of whom has exhibited, in his *Principia* and *Optics*, the most perfect exemplifications which have yet appeared, of the cautious logic recommended by Bacon and Locke; while the other, in defending against the assaults of Leibnitz the metaphysical principles on which the Newtonian philosophy proceeds, has been led, at the same time, to vindicate the authority of various other truths, of still higher importance, and more general interest.

The chief subjects of dispute between Leibnitz and Clarke, so far as the principles of the Newtonian philosophy are concerned, have been long ago settled, to the entire satisfaction of the learned world. The *monads*, and the *plenum*, and the *pre-established harmony* of Leibnitz, already rank, in the public estimation, with the vortices of Descartes, and the plastic nature of Cudworth; while the theory of gravitation prevails everywhere over all opposition; and (as Mr. Smith remarks) “has advanced to the acquisition of the most universal empire that was ever established in philosophy.” On these points, therefore, I have only to refer my readers to the collection published by Dr Clarke, in 1717, of the controversial papers which passed between him and Leibnitz during the two preceding years; a correspondence equally curious and instructive; and which, it is to be lamented, that the death of Leibnitz in 1716 prevented from being longer continued.¹

passing over a multitude of other names well worthy to be recorded in the annals of metaphysical science. Among these, I shall only mention the name of Boyle, to whom the world is indebted, beside some very acute remarks and many fine illustrations of his own upon metaphysical questions of the highest moment, for the philosophical arguments in defence of religion, which have added so much lustre to the names of Derham and Bentley; and far above both, to that of Clarke.* The *remarks* and *illustrations*, which I here refer to, are to be found in his *Inquiry into the Vulgar Notion of Nature*, and in his *Essay, inquiring whether, and how, a Naturalist should consider Final Causes*. Both of these tracts display powers which might have placed their author on a level with Descartes and Locke, had not his taste and inclination determined him more strongly to other pursuits. I am inclined to think, that neither of them is so well known as were to be wished. I do not even recollect to have seen it anywhere noticed, that some of the most striking and beautiful instances of design in the order of the material world, which occur in the Sermons preached at Boyle's *Lecture*, are borrowed from the works of the founder.†

Notwithstanding, however, these great merits, he has written too little on such abstract subjects to entitle him to a place among English metaphysicians; nor has he, like Newton, started any leading thoughts which have since given a new direction to the studies of metaphysical inquirers. From the slight specimens he has left, there is reason to conclude, that his mind was still more happily turned than that of Newton, for the prosecution of that branch of science to which their contemporary Locke was then beginning to invite the attention of the public.

¹ From a letter of Leibnitz to M. Remond de Montmort, it appears that he considered Newton, and not

* To the English reader it is unnecessary to observe, that I allude to the Sermons preached at the Lecture founded by the Honourable Robert Boyle.

† Those instances, more especially, which are drawn from the anatomical structure of animals, and the adaptation of their perceptive organs to the habits of life for which they are destined.

Although Newton does not appear to have devoted much of his time to Metaphysical researches, yet the general spirit of his physical investigations has had a great, though indirect, influence on the metaphysical studies of his successors. It is justly and profoundly remarked by Mr Hume, that "while Newton *seemed* to draw off the veil from some of the mysteries of nature, he showed, at the same time, the imperfections of the mechanical philosophy, and thereby restored her ultimate secrets to that obscurity in which they ever did, and ever will remain." In this way, his discoveries have co-operated powerfully with the reasonings of Locke in producing a general conviction of the inadequacy of our faculties to unriddle those sublime enigmas on which Descartes, Malebranche, and Leibnitz, had so recently wasted their strength, and which, in the ancient world, were regarded as the only fit objects of philosophical curiosity. It is chiefly too since the time of Newton that the ontology and pneumatology of the dark ages have been abandoned for inquiries resting on the solid basis of experience and analogy; and that philosophers have felt themselves emboldened by his astonishing discoveries concerning the more distant parts of the material universe, to argue from the known to the unknown parts of the moral world. So completely has the prediction been verified which he himself hazarded, in the form of a query, at the end of his *Optics*, that "if natural philosophy should continue to be improved in its various branches, the bounds of moral philosophy would be enlarged also."

How far the peculiar cast of Newton's genius qualified him for prosecuting successfully the study of Mind, he has not afforded us sufficient *data* for judging; but such was the admiration with which his transcendent powers as a Mathematician and Natural Philosopher were universally regarded, that the slightest of his hints on other subjects have been eagerly seized upon as indisputable axioms, though sometimes with little other evidence in their favour but the supposed sanction of his authority.¹ The part of his works, however, which chiefly led me to connect his name with that of Clarke, is a passage in the

Clarke, as his real antagonist in this controversy. "M. Clarke, ou plutôt M. Newton, dont M. Clarke soutient les dogmes, est en dispute avec moi sur la philosophie." (Leib. *Op.* Tom. V. p. 33.) From another letter to the same correspondent we learn, that Leibnitz aimed at nothing less than the complete overthrow of the Newtonian philosophy; and that it was chiefly to his grand principle of the *sufficient reason* that he trusted for the accomplishment of this object. "J'ai réduit l'état de notre dispute à ce grand axiome, que rien n'existe ou n'arrive sans qu'il y ait une raison suffisante, pourquoi il en est plutôt ainsi qu'autrement. S'il continue à me le nier, où en sera sa sincérité? S'il me l'accorde, adieu le vuide, les atomes, et toute la philosophie de M. Newton." (Ibid.) See also a letter from Leibnitz to M. des Maizeaux in the same volume of his works, p. 39.

¹ Witness Hartley's *Physiological Theory of the Mind*, founded on a query in Newton's *Optics*; and a long list of theories in medicine, grafted on a hint thrown out in the same query, in the form of a modest conjecture.

Scholium annexed to his *Principia*,¹ which may be considered as the germ of the celebrated argument *a priori* for the existence of God, which is commonly, though, I apprehend, not justly, regarded as the most important of all Clarke's contributions to Metaphysical Philosophy. I shall quote the passage in Newton's own words, to the oracular conciseness of which no English version can do justice.

"Æternus est et infinitus, omnipotens et omnisciens; id est, durat ab æterno in æternum, et adest ab infinito in infinitum.... Non est æternitas et infinitas, sed æternus et infinitus; non est duratio et spatium, sed durat et adest. Durat semper et adest ubique, et existendo semper et ubique durationem et spatium constituit."² Proceeding on these

¹ This *scholium*, it is to be observed, first appeared at the end of the second edition of the *Principia*, printed at Cambridge in 1713. The former edition, published at London in 1687, has no *scholium* annexed to it. From a passage, however, in a letter of Newton's to Dr Bentley (dated 1692), it seems probable, that as far back, at least, as that period, he had thoughts of attempting a proof *a priori* of the existence of God. After some new illustrations, drawn from his own discoveries, of the common argument from *final causes*, he thus concludes. "There is yet another argument for a Deity, which I take to be a very strong one; but, till the principles on which it is grounded are better received, I think it more advisable to let it sleep." (*Four Letters from Sir I. Newton to Dr Bentley*, p. 11. London, Dodsley, 1756.)

It appears from this passage, that Newton had no intention, like his predecessor Descartes, to supersede, by any new argument of his own for the existence of God, the common one drawn from the consideration of *final causes*; and, therefore, nothing could be more uncandid than the following sarcasm pointed by Pope at the laudable attempts of his two countrymen to add to the evidence of this conclusion, by deducing it from *other* principles:

"Let others creep by timid steps and slow,
On plain experience lay foundations low,
By common sense to common knowledge bred,
And last to Nature's cause thro' Nature led:
We nobly take the high *priori*-road,
And reason downwards till we doubt of God."

That Pope had Clarke in his eye when he wrote these lines, will not be doubted by those who recollect the various other occasions in which he has stepped out of his way, to vent an impotent spleen against this excellent person.

"Let Clarke live half his life the poor's support,
But let him live the other half at court."

And again:

"Even in an ornament its place remark;
Nor in a hermitage set Dr Clarke:"

in which last couplet there is a manifest allusion to the bust of Clarke, placed in a hermitage by Queen Caroline, together with those of New ~~B.~~ Boyle, Locke, and Wollaston. See some fine verses on these busts in a poem called the *Grotto*, by Matthew Green.

² Thus translated by Dr Clarke, "God is eternal and infinite, omnipotent and omniscient; that is, he endures from everlasting to everlasting, and is present from infinity to infinity. He is not eternity or infinity, but eternal and infinite. He is not duration or space, but he endures and is present. He endures always, and is present everywhere, and by existing always and everywhere, constitutes duration and space." (See Clarke's *Fourth Reply to Leibnitz*.)

principles, Dr Clarke argued, that, as immensity and eternity (which force themselves irresistibly on our belief as *necessary* existences, or, in other words, as existences of which the annihilation is impossible) are not *substances*, but *attributes*, the immense and eternal Being, whose attributes they are, must exist of necessity also. The existence of God, therefore, according to Clarke, is a truth that follows with demonstrative evidence from those conceptions of space and time which are inseparable from the human mind. . . . “ These (says Dr Reid) are the speculations of men of superior genius; but whether they be as solid as they are sublime, or whether they be the wanderings of imagination in a region beyond the limits of the human understanding, I am at a loss to determine.” After this candid acknowledgment from Dr Reid, I need not be ashamed to confess my own doubts and difficulties on the same question.¹

But although the argument, as stated by Clarke, does not carry complete satisfaction to my mind, I think it must be granted that there is something peculiarly wonderful and overwhelming in those conceptions of immensity and eternity, which it is not less impossible to banish from our thoughts, than the consciousness of our own existence. Nay, further, I think that these conceptions are very intimately connected with the fundamental principles of Natural Religion. For when once we have established, from the evidences of design everywhere manifested around us, the existence of an intelligent and powerful *cause*, we are unavoidably led to apply to this *cause* our conceptions of *immensity* and *eternity*, and to conceive Him as filling the infinite extent of both with his presence and with his power. Hence we associate with the idea of God those awful impressions which are naturally produced by the idea of infinite space, and perhaps still more by the idea of endless duration. Nor is this all. It is from the immensity of space that the notion of infinity is originally derived; and it is hence that we transfer the expression, by a sort of metaphor, to other subjects. When we speak, therefore, of *infinite* power, wisdom, and goodness, our notions, if not wholly borrowed from space, are at least greatly aided by this analogy; so that the conceptions of Immensity and Eternity, if they do not of themselves *demonstrate* the existence of God, yet necessarily enter into the ideas we form of his nature and attributes.

To these various considerations it may be added, that the notion of *necessary existence* which we derive from the contemplation of Space and of Time, renders the same notion,

¹ An argument substantially the same with this for the existence of God, is hinted at very distinctly by Cudworth, *Intellect. System*, Chap. V. sect. 3, 4. Also by Dr Henry More, *Enchir. Metaph.* Cap. 8. sect. 8. See Mosheim's *Trans. of Cudworth*, Tom. II. p. 356.

when applied to the Supreme Being, much more easy to be apprehended than it would otherwise be.

It is not, therefore, surprising, that Newton and Clarke should have fallen into that train of thought which encouraged them to attempt a demonstration of the being of God from our conceptions of Immensity and Eternity; and still less is it to be wondered at, that, in pursuing this lofty argument, they should have soared into regions where they were lost in the clouds.

I have said above, that Clarke's demonstration seems to have been suggested to him by a passage in Newton's *Scholium*. It is, however, more than probable that he had himself struck into a path very nearly approaching to it, at a much earlier period of his life. The following anecdote of his childhood, related, upon his own authority, by his learned and authentic, though, in many respects, weak and visionary biographer (Whiston), exhibits an interesting example of an anomalous developement of the powers of reflection and abstraction, at an age when, in ordinary cases, the attention is wholly engrossed with sensible objects. Such an inversion of the common process of nature in unfolding our different faculties, is perhaps one of the rarest phenomena in the intellectual world; and, wherever it occurs, may be regarded as strongly symptomatic of something peculiar and decided in the philosophical character of the individual:

"One of his parents," says Whiston, "asked him when he was very young, Whether God could do every thing? He answered, Yes! He was asked again, Whether God could tell a lie? He answered, No! And he understood the question to suppose, that this was the only thing that God could not do; nor durst he say, so young was he then, that he thought there was any thing else which God could not do; while yet, well he remembered, that he had, *even then, a clear conviction in his own mind, that there was one thing which God could not do;—that he could not annihilate that space which was in the room where they were.*"¹

¹ The question concerning the necessary existence of Space and of Time formed one of the principal subjects of discussion between Clarke and Leibnitz. According to the former, space and time are, both of them, infinite, immutable, and indestructible. According to his antagonist, "space is nothing but the order of things co-existing," and "time nothing but the order of things successive!" The notion of real absolute Space, in particular, he pronounces to be *a mere chimera and superficial imagination*; classing it with those prejudices which Bacon called *idola tribus*. (See his 4th Paper, § 14.)

It has always appeared to me a thing quite inexplicable, that the great majority of philosophers, both in Germany and in France, have, on the above question, decided in favour of Leibnitz. Even D'Alembert himself, who, on most metaphysical points, reasons so justly and so profoundly, has, in this instance, been carried along by the prevailing opinion (or, perhaps, it would be more correct to say, by the fashionable phraseology) among his

With this early and deep impression on his mind, it is easy to conceive how Newton's *Scholium* should have encouraged him to resume the musings of his *boyish days*, concerning the necessary existence of space; and to trace, as far as he could, its connection with the principles of natural theology. But the above anecdote affords a proof how strongly his habits of thought had long before predisposed him for the prosecution of a metaphysical idea, precisely the same with that on which this scholium proceeds.

It would be superfluous to dwell longer on the history of these speculations, which, whatever value they may possess in the opinion of persons accustomed to deep and abstract reasoning, are certainly not well adapted to ordinary or to uncultivated understandings. This consideration furnishes, of itself, no slight presumption, that they were not intended to be the *media* by which the bulk of mankind were to be led to the knowledge of truths so essential to human happiness; and, accordingly, it was on this very ground, that Bishop Butler, and Dr Francis Hutcheson, were induced to strike into a different and more popular path for establishing the fundamental principles of religion and morality. Both of these writers appear to have communicated, in very early youth, their doubts and objections to Dr Clarke; and to have had, even then, a glimpse of those inquiries by which they were afterwards to give so new and so fortunate a direction to the ethical studies of their countrymen. It is sufficient here to remark this circumstance as an important step

countrymen. "Y'auroit-il un espace, s'il n'y avoit point de corps, et une durée s'il n'y avoit rien? Ces questions viennent, ce me semble, de ce qu'on suppose au temps et à l'espace plus de réalité qu'ils n'en ont. . . . Les enfants, qui disent que le vuide n'est rien, ont raison parce qu'ils s'en tiennent au simples notions du sens commun;* et les philosophes, que veulent réaliser le vuide se perdent dans leurs spéculations: le vuide a été enfanté par les abstractions, et voilà l'abus d'une méthode si utile à bien des égards. *S'il n'y avoit point de corps et de succession, l'espace et le temps seroient possibles, mais ils n'existeroient pas.*" (*Mélanges*, &c. T. V. § xvi.) Bailly, a writer by no means partial to D'Alembert, quotes, with entire approbation, the foregoing observations; subjoining to them, in the following terms, his own judgment on the merits of this branch of the controversy between Clarke and Leibnitz: "La notion du temps et de l'espace, est un des points sur lesquels Leibnitz a combattu contre Clarke; mais il nous semble que l'Anglois n'a rien opposé de satisfaisant aux raisons de Leibnitz." (*Éloge de Leibnitz*.)

As for the point here in dispute, I must own, that it does not seem to me a fit subject for argument: inasmuch as I cannot even form a conception of the proposition contended for by Leibnitz. The light in which the question struck Clarke in his childhood, is the same in which I am still disposed to view it; or rather, I should say, is the light in which I must ever view it, while the frame of my understanding continues unaltered. Of what *data* is human reason possessed, from which it is entitled to argue in opposition to truths, the contrary of which it is impossible not only to prove, but to express in terms comprehensible by our faculties?

For some remarks on the scholastic controversies concerning *space* and *time*, see the First Part of this *Dissertation*, Note I. See also Locke's *Essay*, Book ii. Chap. 13. § § 16, 17, 18.

* I quote the sequel of this passage on the authority of Bailly (see his *Éloge on Leibnitz*), for it is not to be found in the copy of the *Mélanges* before me, printed at Amsterdam in 1767.

in the progress of moral philosophy. The farther illustration of it properly belongs to another part of this discourse.

The chief glory of Clarke, as a metaphysical author, is due to the boldness and ability with which he placed himself in the breach against the Necessitarians and Fatalists of his times. With a mind far inferior to that of Locke, in comprehensiveness, in originality, and in fertility of invention, he was nevertheless the more wary and skilful disputant of the two, possessing, in a singular degree, that reach of thought in grasping remote consequences, which effectually saved him from those rash concessions into which Locke was frequently betrayed by the greater warmth of his temperament, and vivacity of his fancy. This logical foresight (the natural result of his habits of mathematical study) rendered him peculiarly fit to contend with adversaries, eager and qualified to take advantage of every vulnerable point in his doctrines; but it gave, at the same time, to his style a tameness, and monotony, and want of colouring, which never appear in the easy and spirited, though often unfinished and unequal, sketches of Locke. Voltaire has somewhere said of him, that he was a mere reasoning machine (*un moulin à raisonnement*), and the expression (though doubtless much too unqualified) possesses a merit, in point of just discrimination, of which Voltaire was probably not fully aware.¹

¹ In the extent of his learning, the correctness of his taste, and the depth of his scientific acquirements, Clarke possessed indisputable advantages over Locke; with which advantages he combined another not less important, the systematical steadiness with which his easy fortune and unbroken leisure enabled him to pursue his favourite speculations through the whole course of his life.

On the subject of Free-will, Locke is more indistinct, undecided, and inconsistent, than might have been expected from his powerful mind, when directed to so important a question. This was probably owing to his own strong feelings in favour of man's moral liberty, struggling with the deep impression left on his philosophical creed by the writings of Hobbes, and with his deference for the talents of his own intimate friend, Anthony Collins.* That Locke conceived himself to be an advocate for *free-will*, appears indisputably from many expressions in his Chapter on *Power*; and yet, in that very chapter, he has made various concessions to his adversaries, in which he seems to yield all that was contended for by Hobbes and Collins: And, accordingly, he is ranked, with some appearance of truth, by Priestley, with those who, while they opposed verbally the scheme of necessity, have adopted it substantially, without being aware of their mistake.

In one of Locke's letters to Mr Molyneux, he has stated, in the strongest possible terms, his conviction of man's free agency; resting this conviction entirely on our indisputable consciousness of the *fact*. This declaration of Locke I consider as well worthy of attention in the argument about Free-will; for, although in questions of pure speculation, the authority of great names is entitled to no weight, excepting in so far as it is supported by solid reasoning, the case is otherwise with *facts* relating to the phenomena of the human mind. The patient attention with which Mr Locke had studied these very nice phenomena during the course of a long life, gives to the results of his metaphysical experience a value of the same sort, but much greater in degree, with that which we attach to a delicate experiment in chemistry, when vouched by a Black or a Davy. The ultimate

* See Note (Q.)

I have already taken notice of Clarke's defence of moral liberty in opposition to Leibnitz; but soon after this controversy was brought to a conclusion by the death of his antagonist, he had to resume the same argument, in reply to his countryman, Anthony Collins; who, following the footsteps of Hobbes, with logical talents not inferior to those of his master, and with a weight of personal character in his favour, to which his master had no pretensions;¹ gave to the cause which he so warmly espoused, a degree of credit among sober and serious inquirers, which it had never before possessed in England. I have reserved, therefore, for this place, the few general reflections which I have to offer on this endless subject of controversy. In stating these, I shall be the less anxious to condense my thoughts, as I do not mean to return to the discussion in the sequel of this historical sketch. Indeed, I do not know of anything that has been advanced by later writers, in support of the scheme of necessity, of which the germ is not to be found in the inquiry of Collins.

In order to enter completely into the motives which induced Clarke to take so zealous and so prominent a part in the dispute about Free Will, it is necessary to look back to the system of Spinoza; an author, with whose peculiar opinions I have hitherto avoided to distract my readers' attention. At the time when he wrote, he does not appear to have made

appeal, after all, must be made by every person to his own consciousness; but when we have the experience of Locke on the one hand, and that of Priestley and Belsham on the other, the contrast is surely sufficient to induce every cautious inquirer to re-examine his feelings before he allows himself to listen to the statements of the latter in preference to that of the former.

For the information of some of my readers, it may be proper to mention that it has of late become fashionable among a certain class of metaphysicians, boldly to assert, that the evidence of *their* consciousness is decidedly in favour of the scheme of necessity.

But to return to Mr Locke. The only consideration on this subject which seems to have staggered him, was the difficulty of reconciling this opinion with the prescience of God. As to this theological difficulty, I have nothing to say at present. The only question which I consider as of any consequence, is the matter of fact; and, on this point, nothing can be more explicit and satisfactory than the words of Locke. In examining these, the attentive reader will be satisfied, that Locke's declaration is not (as Priestley asserts) in favour of the Liberty of Spontaneity, but in favour of the Liberty of Indifference, for, as to the former, there seems to be no difficulty in reconciling it with the prescience of God. "I own (says Mr Locke) freely to you the weakness of my understanding, that though it be unquestionable that there is omnipotence and omniscience in God our Maker, and though *I cannot have a clearer perception of anything than that I am free*; yet I cannot make freedom in man consistent with omnipotence and omniscience in God, though I am as fully persuaded of both as of any truth I most firmly assent to; and therefore I have long since given off the consideration of that question; resolving all into this short conclusion, that, *if it be possible for God to make a free agent, then man is free, though I see not the way of it.*"

¹ In speaking disrespectfully of the personal character of Hobbes, I allude to the base servility of his political principles, and to the suppleness with which he adapted them to the opposite interests of the three successive governments under which his literary life was spent. To his private virtues the most honourable testimony has been borne, both by his friends and by his enemies.

many proselytes; the extravagant and alarming consequences in which his system terminated, serving with most persons as a sufficient antidote against it. Clarke was probably the first who perceived distinctly the logical accuracy of his reasoning; and that, if the principles were admitted, it was impossible to resist the conclusions deduced from them.¹ It seems to have been the object both of Leibnitz and of Collins, to obviate the force of this indirect argument against the scheme of necessity, by attempting to reconcile it with the moral agency of man; a task which, I think, it must be allowed, was much less ably and plausibly executed by the former than by the latter. Convinced, on the other hand, that Spinoza had reasoned from his premises much more rigorously than either Collins or Leibnitz, Clarke bent the whole force of his mind to demonstrate that these premises were false; and, at the same time, to put incautious reasoners on their guard against the seducing sophistry of his antagonists, by showing, that there was no medium between admitting the free-agency of man, and of acquiescing in all the monstrous absurdities which the creed of Spinoza involves.

Spinoza,² it may be proper to mention, was an Amsterdam Jew of Portuguese extraction, who (with a view probably to gain a more favourable reception to his philosophical dogmas) withdrew himself from the sect in which he had been educated, and afterwards appears to have lived chiefly in the society of Christians;³ without, however, making any public profession of the Christian faith, or even submitting to the ceremony of baptism. In his philosophical creed, he at first embraced the system of Descartes, and began his literary career with

¹ Dr Reid's opinion on this point coincides exactly with that of Clarke. See his *Essays on the Active Powers of Man* (p. 289, 4to Edition), where he pronounces the system of Spinoza to be "the genuine, and the most tenable system of necessity."

² Born 1632, died 1677. It is observed by Bayle, that "although Spinoza was the first who reduced Atheism to a system, and formed it into a body of doctrine, connected according to the method of geometricians, yet, in other respects, his opinion is not new, the substance of it being the same with that of several other philosophers, both ancient and modern, European and Eastern." See his *Dict. art. Spinoza*, and the authorities in Note (A.)

It is asserted by a late German writer, that "Spinoza has been little heard of in England, and not at all in France, and that he has been zealously defended and attacked by Germans alone." The same writer informs us, that "the philosophy of Leibnitz has been little studied in France, and not at all in England." (*Lectures on the History of Literature*, by Fred. Schlegel. English trans. published at Edin. 1818. Vol. II. p. 243.)

Is it possible that an author who pronounces so dogmatically upon the philosophy of England, should never have heard the name of Dr Clarke?

³ The Synagogue were so indignant at his apostacy, that they pronounced against him their highest sentence of excommunication called *Schammata*. The form of the sentence may be found in the Treatise of Selden, *De Jure Naturæ et Gentium*, Lib. IV. c. 7. It is a document of some curiosity, and will scarcely suffer by a comparison with the Popish form of excommunication recorded by Sterne. For some farther particulars with respect to Spinoza see Note (R.) °

a work entitled, *Renati Descartes Principiorum Philosophiæ, Pars Prima et Secunda, More Geometrico Demonstratæ*, 1663. It was, however, in little else than his physical principles that he agreed with Descartes; for no two philosophers ever differed more widely in their metaphysical and theological tenets. *Fontenelle* characterizes his system as a “Cartesianism pushed to extravagance” (*une Cartesianisme outrée*): an expression which, although far from conveying a just or adequate idea of the whole spirit of his doctrines, applies very happily to his boldness and pertinacity in following out his avowed principles to the philosophical consequences which he conceived them to involve. The reputation of his writings, accordingly, has not entirely (excepting perhaps in Germany and the Netherlands) with the philosophy on which they were grafted: although some of the most odious opinions contained in them are still, like the *Platon* that obtruded on the world, under the disguise of a new form, and of a philosophy less revolting to modern taste.

In no part of Spinoza's works has he avowed himself a Deist; but it will not be disputed, by those who comprehend the drift of his reasonings, that, in point of practical tendency, Atheism and Spinozism are one and the same. In this respect, we may apply to Spinoza what I may add to Vanini also) what Cicero has said of Epicurus: *Verbis reliquit, sed sententiâ*.—a remark which coincides exactly with an expression of Newton's in the *Scholium* at the end of the *Principia*: “*DEUS sine dominio, providentia, et causis finibus, nihil aliud est quam FATUM et NATURA.*”

Among other doctrines of natural and revealed religion which Spinoza affected to embrace, was that of the Divine Omnipresence; a doctrine which, combined with the Plenum of Descartes, led him, by a short and plausible process of reasoning, to the revival of the old theory which represented God as *the soul of the world*: or rather to that identification of God and of the material universe, which I take to be still more agreeable to the idea of Spinoza.² I am particularly anxious to direct the attention of my readers to this part of

¹ One of the most elaborate and acute refutations of Spinozism which has yet appeared is to be found in Bayle's Dictionary, where it is described as “the most monstrous scheme imaginable, and the most diametrically opposite to the clearest notions of the mind.” The same author affirms, that “it has been only overthrown even by the weakest of its adversaries.”—“It does not, indeed, appear possible” (as Mr Maclaurin has observed) “to invent another system equally absurd; amounting (as it does in fact) to this proposition, that there is but one substance in the universe, endowed with infinite attributes (particularly infinite extension and cogitation), which produces all other things necessarily as its own modifications, and which alone is, in all events, both physical and moral, at once cause and effect, agent and patient.”—*View of Newton's Discoveries*, Book I. Chap. 4.

² Spinoza supposes that there are in God two eternal properties, thought and extension; and as he held, with Descartes, that extension is the essence of matter, he must necessarily have conceived *materiality* to be

his system, as I conceive it to be at present very generally misrepresented, or, at least, very generally misunderstood; a thing not to be wondered at, considering the total neglect

an essential attribute of God. "Per Corpus intelligo modum, qui Dei essentiam quatenus ut res extensa consideratur, certo et determinato modo exprimit." (*Ethica ordine Geometrico Demonstrata*. Pars 2. Defin. 1. See also *Ethic.* Pars 1. Prop. 14.) With respect to the other attributes of God, he held, that God is the cause of all things; but that he acts, not from choice, but from necessity; and, of consequence, that he is the involuntary author of all the good and evil, virtue and vice, which are exhibited in human life. "Res nullo alio modo, neque alio ordine a Deo produci potuerunt, quam productæ sunt." (*Ibid.* Pars 1. Prop. 33.) In one of his letters to Mr Oldenburgh (Letter 21), he acknowledges, that his ideas of God and of nature were very different from those entertained by modern Christians; adding by way of explanation, "Deum rerum omnium causam immanentem, non vero transeuntem statuo;"—an expression to which I can annex no other meaning but this, that God is inseparably and essentially united with his works, and that they form together but one being.

The diversity of opinions entertained concerning the nature of Spinozism has been chiefly owing to this, that some have formed their notions of it from the books which Spinoza published during his life, and others from his posthumous remains. It is in the last alone (particularly in his *Ethics*) that his system is to be seen completely unveiled and undisguised. In the former, and also in the letters addressed to his friends, he occasionally accommodates himself, with a very temporizing spirit, to what he considered as the prejudices of the world. In proof of this, see his *Tractatus Theologico-Politicus*, and his epistolary correspondence, *passim*; above all, his letter to a young friend who had apostatized from Protestantism to the Catholic Church. The letter is addressed, Nobilissimo Juveni, Alberto Burgh. (*Spin. Op.* T. II. p. 695.)

The edition of Spinoza's works, to which my references are made, is the complete and very accurate one published at Jena in 1802, by Henr. Eberh. Gottlob Paulus, who styles himself Doctor and Professor of Theology.

This learned divine is at no pains to conceal his admiration of the character as well as talents of his author; nor does he seem to have much to object to the system of Spinozism, as explained in his posthumous work upon *Ethics*; a work which, the editor admits, contains the only genuine exposition of Spinoza's creed. "Sedes systematicæ quod sibi condidit in ethica est." (*Pref. Iteratæ Editionis*, p. ix.) In what manner all this was reconciled in his theological lectures with the doctrines either of natural or of revealed religion, it is not very easy to imagine. Perhaps he only affords a new example of what Dr Clarke long ago remarked, that "Believing too much and too little have commonly the luck to meet together, like two things moving contrary ways in the same circle." (*Third Letter to Dodwell*.)

A late German writer, who, in his own opinions, has certainly no leaning towards Spinozism, has yet spoken of the moral tendency of Spinoza's writings, in terms of the warmest praise. "The morality of Spinoza (says M. Fred. Schlegel) is not indeed that of the Bible, for he himself was no Christian, but it is still a pure and noble morality, resembling that of the ancient Stoics, perhaps possessing considerable advantages over that system. That which makes him strong when opposed to adversaries, who do not understand or feel his depth, or who ungenerously have fallen into errors not much different from his, is not merely the scientific clearness and decision of his intellect, but in a much higher degree the openheartedness, strong feeling, and conviction, with which all that he says seems to gush from his heart and soul." (*Lect. of Fred. Schlegel*, Eng. Trans. Vol. II. p. 244.) The rest of the passage, which contains a sort of apology for the system of Spinoza, is still more curious.

Although it is with the metaphysical tenets of Spinoza alone that we are immediately concerned at pre-

into which his works have long fallen. It is only in this way I can account for the frequent use which has most unfairly been made of the term *Spinozism* to stigmatise and discredit some doctrines, or rather some modes of speaking, which have been sanctioned, not only by the wisest of the ancients, but by the highest names in English philosophy and literature; and which, whether right or wrong, will be found, on a careful examination and comparison, not to have the most distant affinity to the absurd creed with which they have been confounded. I am afraid that Pope, in the following lines of the *Dunciad*, suffered himself so far to be misled by the malignity of Warburton, as to aim a secret stab at Newton and Clarke, by associating their figurative, and not altogether unexceptionable language,

sent, it is not altogether foreign to my purpose to observe, that he had also speculated much about the principles of government; and that the coincidence of his opinions with those of Hobbes, on this last subject, was not less remarkable than the similarity of their views on the most important questions of metaphysics and ethics. Unconnected as these different branches of knowledge may at first appear, the theories of Spinoza and of Hobbes concerning *all* of them, formed parts of one and the same system; the whole terminating ultimately in the maxim with which (according to Plutarch) Anaxarchus consoled Alexander after the murder of Clytus: *Παν το πράχθιν απο τη κρατύντος δικαίον είναι*. Even in discussing the question about Liberty and Necessity, Hobbes cannot help glancing at this political corollary. "The power of God alone is a sufficient justification of any action he doth." . . . "That which he doth is made just by his doing it." . . . "Power irresistible justifies all actions really and properly, in whomsoever it be found." (*Of Liberty and Necessity*, addressed to the Lord Marquis of Newcastle.) Spinoza has expressed himself exactly to the same purpose. (See his *Tractatus Politicus*, Cap. 2. §§ 3, 4.) So steadily, indeed, is this practical application of their abstract principles kept in view by both these writers, that not one generous feeling is ever suffered to escape the pen of either in favour of the rights, the liberties, or the improvement of their species.

The close affinity between those abstract theories which tend to degrade human nature, and that accommodating morality which prepares the minds of men for receiving passively the yoke of slavery, although too little attended to by the writers of literary history, has not been overlooked by those deeper politicians who are disposed (as has been alleged of the first of the Cæsars) to have considered their fellow-creatures "but as rubbish in the way of their ambition, or tools to be employed in removing it." This practical tendency of the Epicurean philosophy is remarked by one of the wisest of the Roman statesmen; and we learn from the same high authority, how fashionable this philosophy was in the higher circles of his countrymen, at that disastrous period which immediately preceded the ruin of the Republic. "Nunquam audiui in Epicuri schola, Lycurgum, Solonem, Miltiadem, Themistoclem, Epaminondam nominari; qui in ore sunt ceterorum omnium philosophorum." (*De Fin. Lib. ii. c. 21.*) "Nec tamen Epicuri licet oblivisci, si cupiam; cujus imaginem non modo in tabulis nostri familiares, sed etiam in poculis, et annulis habent." (*Ibid. Lib. v. c. 1.*)

The prevalence of Hobbism at the court of Charles II. (a fact acknowledged by Clarendon himself) is but one of the many instances which might be quoted from modern times in confirmation of these remarks.

The practical tendency of such doctrines, as would pave the way to universal scepticism, by holding up to ridicule the extravagancies and inconsistencies of the learned, is precisely similar. We are told by Tacitus (*Annal. Lib. 14*), that Nero was accustomed, at the close of a banquet, to summon a party of philosophers, that he might amuse himself with listening to the endless diversity and discordancy of their respective systems; nor were there wanting philosophers at Rome, the same historian adds, who were flattered to be thus exhibited as a

concerning *space* (when they called it the *sensorium* of the Deity), with the opinion of Spinoza, as I have just explained it.¹

"Thrust some Mechanic Cause into His place,
Or bind in matter, or diffuse in space."

How little was it suspected by the poet, when this sarcasm escaped him, that the charge of Spinozism and Pantheism was afterwards to be brought against himself for the sublimest passage to be found in his writings!

"All are but parts of one stupendous whole,
Whose body Nature is, and God the soul
Lives through all Life, extends through all extent,
Spreads undivided, operates unspent."²

Bayle was, I think, the writer who first led the way to this misapplication of the term *Spinozism*; and his object in doing so, was plainly to destroy the effect of the most refined and philosophical conceptions of the Deity which were ever formed by the unassisted power of human reason.

spectacle at the table of the Emperor. What a deep and instructive moral is conveyed by this anecdote¹ and what a contrast does it afford to the sentiment of one of Nero's successors, who was himself a philosopher in the best sense of the word, and whose reign furnishes some of the fairest pages in the annals of the human race!

"I search for truth (says Marcus Antoninus), by which no person has ever been injured" *Ζητῶ γὰρ τὴν ἀλήθειαν, ὑφ' ἧς οὐδὲς πῶποτε βλάβηται.*

¹ Warburton, indeed, always professes great respect for Newton, but of his hostility to Clarke it is unnecessary to produce any other proof than his note on the following line of the Dunciad

"Where Tindal dictates, and Silenus snores."

B. iv. l. 492.

May I venture to add, that the noted line of the *Essay on Man*,

"And showed a Newton as we show an ape,"

could not possibly have been written by any person impressed with a due veneration for this glory of his species?

² This passage (as Warburton has remarked)¹ bears a very striking analogy to a noble one in the old Orphic verses quoted in the treatise *Περὶ κόσμου*, ascribed to Aristotle, and it is not a little curious, that the same ideas occur in some specimens of H. loo poetry, translated by Sir W. Jones, more particularly in the *Hymn to Narayana*, or the Spirit of God, taken, as he informs us, from the writings of their ancient authors;

Omniscient Spirit, whose all-ruling power
Bids from each sense bright emanations beam;
Glow in the rainbow sparkles in the stream,
&c. &c.

" *Estne Dei sedes nisi terra, et pontus, et aer,
Et oelum, et virtus? Superos quid quaerimus ultra?
Jupiter est quodcumque vides, quocumque moveris.*"

" *Is there a place that God would choose to love
Beyond this earth, the seas, yon Heaven above
And virtuous minds, the noblest throne for Jove?
Why seek we farther then? Behold around,
How all thou seest does with the God abound,
Jove is alike to all, and always to be found.*"

Rowe's *Lucan*.

Who, but Bayle, could have thought of extracting anything like Spinozism from such versés as these!

On a subject so infinitely disproportioned to our faculties, it is vain to expect language which will bear a logical and captious examination. Even the Sacred Writers themselves are forced to adapt their phraseology to the comprehension of those to whom it is addressed, and frequently borrow the figurative diction of poetry to convey ideas which must be interpreted, not according to the letter, but the spirit of the passage. It is thus that thunder is called the voice of God; the wind, His breath; and the tempest, the blast of His nostrils. Not attending to this circumstance, or rather not choosing to direct to it the attention of his readers, Spinoza has laid hold of the well known expression of St Paul, that "in God we live, and move, and have our being," as a proof that the ideas of the apostle, concerning the Divine Nature, were pretty much the same with his own; a consideration which, if duly weighed, might have protected some of the passages above quoted from the uncharitable criticisms to which they have frequently been exposed.¹

¹ Mr Gibbon, in commenting upon the celebrated lines of Virgil,

" *Spiritus intus alit, totumque refusa per artus,
Mens agitat molem, et magno se corpore miscet,*"

observes, that "the mind which is infused into the different parts of matter, and which mingles itself with the mighty mass, scarcely retains any property of a spiritual substance, and bears too near an affinity to the principles which the impious Spinoza revived rather than invented." He adds, however, that "the poverty of human language, and the obscurity of human ideas, make it difficult to speak worthily of the GREAT FIRST CAUSE, and that our most religious poets (particularly Pope and Thomson), in striving to express the presence and energy of the Deity in every part of the universe, deviate unwarily into images which require a favourable construction. But these writers (he candidly remarks) deserve that favour, by the sublime manner in which they celebrate the Great Father of the universe, and by those effusions of love and gratitude which are inconsistent with the materialist's system." (*Misc. Works*, Vol. II. pp. 509, 510.)

May I be permitted here to remark, that it is not only difficult but impossible to speak of the omnipresence and omnipotence of God, without deviating into such images?

With the doctrine of the *Anima Mundi*, some philosophers, both ancient and modern, have connected

To return, however, to Collins, from whose controversy with Clarke I was insensibly led aside into this short digression about Spinoza: I have already said, that it seems to have been the aim of Collins to vindicate the doctrine of Necessity from the reproach brought on it by its supposed alliance with Spinozism; and to retort upon the partizans of free-will the charges of favouring atheism and immorality. In proof of this I have only to quote the account, given by the author himself, of the plan of his work:

"Too much care cannot be taken to prevent being misunderstood and prejudged, in handling questions of such nice speculation as those of Liberty and Necessity; and, therefore, though I might in justice expect to be read before any judgment be passed on me, I think it proper to premise the following observations:

"1. *First*, Though I deny *liberty* in a certain meaning of that word, yet I contend for *liberty*, as it signifies *a power in man to do as he wills or pleases*.

"2. *Secondly*, When I affirm *necessity*, I contend only for *moral necessity*; meaning thereby, that man, who is an intelligent and sensible being, is determined by his reason and his senses; and I deny man to be subject to such necessity, as is in clocks, watches, and such other beings, which, for want of sensation and intelligence, are subject to an absolute, physical, or mechanical necessity.

"3. *Thirdly*, I have undertaken to show, that the notions I advance are so far from being inconsistent with, that they are the sole foundations of morality and laws, and of rewards and punishments in society; and that the notions I explode are subversive of them."¹

In the prosecution of his argument on this question, Collins endeavours to show, that man is a necessary agent, 1. From our experience. (By *experience* he means our own

another theory, according to which the souls of men are portions of the Supreme Being, with whom they are reunited at death, and in whom they are finally absorbed and lost. To assist the imagination in conceiving this theory, death has been compared to the breaking of a phial of water, immersed in the ocean. It is needless to say, that this incomprehensible jargon has no necessary connection with the doctrine which represents God as the soul of the world, and that it would have been loudly disclaimed, not only by Pope and Thomson, but by Epictetus, Antisthenes, and all the wisest and soberest of the Stoical school. Whatever objections, therefore, may be made to this doctrine, let not its supposed consequences be charged upon any but those who may expressly avow them. On such a subject (as Gibbon has well remarked), "we should be slow to suspect, and still slower to condemn." (*Ibid* p. 510.)

Sir William Jones mentions a very curious modification of this theory of *absorption*, as one of the doctrines of the *Vedanta* school. "The *Vedanta* school represents *Elysian* happiness as a total absorption, though not such as to destroy consciousness, in the Divine Essence." (*Dissertation on the Gods of Greece, Italy, and India*)

¹ *A Philosophical Inquiry concerning Human Liberty*, 3d Edit. Lond. 1735.

consciousness that we *are* necessary agents.) 3. From the impossibility of liberty.¹ 3. From the consideration of the Divine prescience. 4. From the nature and use of rewards and punishments; and, 5. From the nature of morality.²

In this view of the subject, and, indeed, in the very selection of his premises, it is remarkable how completely Collins has anticipated Dr Jonathan Edwards, the most celebrated and indisputably the ablest champion of the scheme of Necessity who has since appeared. The coincidence is so perfect, that the outline given by the former, of the plan of his work, might have served with equal propriety as a preface to that of the latter.

From the above summary, and still more from the whole tenor of the *Philosophical Inquiry*, it is evident, that Collins (one of the most obnoxious writers of his day to divines of all denominations) was not less solicitious than his successor Edwards to reconcile his metaphysical notions with man's accountableness and moral agency. The remarks, accordingly, of Clarke upon Collins's work, are equally applicable to that of Edwards. It is to be regretted that they seem never to have fallen into the hands of this very acute and honest reasoner. As for Collins, it is a remarkable circumstance, that he attempted no reply to this tract of Clarke's, although he lived twelve years after its publication. The reasonings contained in it, together with those on the same subject in his correspondence with Leibnitz, and in his *Demonstration of the Being and Attributes of God*, form, in my humble opinion, the most important as well as powerful of all his metaphysical arguments.³ The adversaries with whom he had to contend were, both of them, eminently distinguished by ingenuity and subtlety, and he seems to have put forth to the utmost his logical strength, in contending with such antagonists. "The liberty or moral agency of man (says his friend Bishop Hoadly) was a darling point to him. He excelled always, and showed a superiority to all, whenever it came into private discourse or public debate. But he never more excelled than when he was pressed with the strength Leibnitz was master of; which made him exert all his talents to set it once again in a clear light, to guard it against the evil of metaphysical obscurities, and to give the finishing stroke to a subject which must ever be the foundation of morality in man, and is the ground of the accountableness of intelligent creatures for all their actions."⁴

¹ See Note (S.)

² See Note (T.)

³ Voltaire, who, in all probability, never read either Clarke or Collins, has said that the former replied to the latter only by *Theological* reasonings: "*Clarke n'a répondu à Collins qu'en Théologie.*" (*Quatrième de l'Encyclopédie, Art. Liberté*.) Nothing can be more remote from the truth. The argument of Clarke is wholly *Metaphysical*; whereas, his antagonist, in various instances, has attempted to wrest to his own purposes the words of Scripture.

⁴ Preface to the Folio Ed. of Clarke's *Works*.—The vital importance which Clarke attached to this ques-

It is needless to say, that neither Leibnitz nor Collins admitted the fairness of the inference which Clarke conceived to follow from the scheme of necessity: But almost every page in the subsequent history of this controversy may be regarded as an additional illustration of the soundness of Clarke's reasonings, and of the sagacity with which he anticipated the fatal errors likely to issue from the system which he opposed.

"Thus (says a very learned disciple of Leibnitz, who made his first appearance as an author about thirty years after the death of his master)¹—Thus, the same chain embraces the physical and moral worlds, binds the past to the present, the present to the future, the future to eternity.

"That wisdom which has ordained the existence of this chain, has doubtless willed that of every link of which it is composed. A CALIGULA is one of those links, and this link is of iron: A MARCUS AURELIUS is another link, and this link is of gold. Both are necessary parts of one whole, which could not but exist. Shall God then be angry at the sight of the iron link? What absurdity! God esteems this link at its proper value: He sees it in its cause, and he approves this cause, for it is good. God beholds moral monsters as he beholds physical monsters. Happy is the link of gold! Still more happy if he know that he is *only fortunate*.² He has attained the highest degree of moral perfection, and is nevertheless without pride, knowing that what he is, is the necessary result of the place which he must occupy in the chain."

"The gospel is the allegorical exposition of this system; the simile of the potter is its summary."³ (Bonnet, T. VIII. pp. 237, 238.)

In what essential respect does this system differ from that of Spinoza? Is it not even more dangerous in its practical tendency, in consequence of the high strain of mystical devotion by which it is exalted?⁴

tion, has given to the concluding paragraphs of his remarks on Collins, an earnestness and a solemnity of which there are not many instances in his writings. These paragraphs cannot be too strongly recommended to the attention of those well-meaning persons, who, in our own times, have come forward as the apostles of Dr Priestley's "great and glorious Doctrine of Philosophical Necessity"

¹ Charles Bonnet, born 1720, died 1793.

² The words in the original are, "Heureux le chaînon d'or! plus heureux encore, s'il sait qu'il n'est qu'heureux" The double meaning of *heureux*, if it render the expression less logically precise, gives it at least an epigrammatic turn, which cannot be served in our language.

³ See Note (U.)

⁴ Among the various forms which religious enthusiasm assumes, there is a certain prostration of the mind, which, under the specious disguise of a deep humility, aims at exalting the Divine perfections, by annihilating all the powers which belong to Human Nature. "Nothing is more usual for fervent devotion (says Sir James Mackintosh, in speaking of some theories current among the Hindoos), than to dwell so

This objection, however, does not apply to the quotations which follow. They exhibit, without any colourings of imagination or of enthusiasm, the scheme of necessity pushed to the remotest and most alarming conclusions which it appeared to Clarke to involve; and as they express the serious and avowed creed of two of our contemporaries (both of them men of distinguished talents), may be regarded as a proof, that the zeal displayed by Clarke against the metaphysical principles which led ultimately to such results, was not so unfounded as some worthy and able inquirers have supposed.

May I be permitted to observe farther on this head, that, as one of these writers spent his life in the pay of a German prince, and as the other was the favourite philosopher of another sovereign, still more illustrious, the sentiments which they were so anxious to proclaim to the world, may be presumed to have been not very offensive (in their judgments) to the ears of their protectors?

"All that is must be (says the Baron de Grimm, addressing himself to the Duke of Saxe-Gotha), All that is must be, even because it is; this is the only sound philosophy; as long as we do not know this universe *a priori* (as they say in the schools), ALL IS NECESSITY.¹ Liberty is a word without meaning, as you shall see in the letter of M. Diderot."

The following passage is extracted from Diderot's letter here referred to:

"I am now, my dear friend, going to quit the tone of a preacher, to take, if I can, that of a philosopher. Examine it narrowly, and you will see that the word *Liberty* is a word devoid of meaning;² that there are not, and that there cannot be free beings; that we

long and so warmly on the meanness and worthlessness of created things, and on the all-sufficiency of the Supreme Being, that it slides insensibly from comparative to absolute language, and in the eagerness of its zeal to magnify the Deity, seems to annihilate everything else." (See *Philosophy of the Human Mind*, Vol. II. p. 529, 2d Ed.)

This excellent observation may serve to account for the zeal displayed by Bonnet, and many other devout men, in favour of the scheme of Necessity. "We have nothing (they frequently and justly remind us) but what we have received."—But the question here is simply a matter of fact, whether we have or have not received from God the gift of Free-Will; and the only argument, it must be remembered, which they have yet been able to advance for the negative proposition, is, that this gift was impossible, even for the power of God; nay, the same argument which annihilates the power of Man, annihilates that of God also, and subjects him, as well as all his creatures, to the control of causes which he is unable to resist. So completely does this scheme defeat the pious views in which it has sometimes originated.—I say *sometimes*; for the very same argument against the liberty of the Will is employed by Spinoza, according to whom the free-agency of man involves the absurd supposition of an *imperium in imperio* in the universe. (*Tractat. Polit. Cap. II. § 6.*)

¹ The logical inference ought undoubtedly to have been, "As long as we know nothing of the universe *a priori*, we are not entitled to say of anything that it either is, or is not, necessary."

² Does not this remark of Diderot apply with infinitely greater force to the word *necessity*, as employed in this controversy?

are only what accords with the general order, with our organization, our education, and the chain of events. These dispose of us invincibly. We can no more conceive a being acting without a motive, than we can one of the arms of a balance acting without a weight. The motive is always exterior and foreign, fastened upon us by some cause distinct from ourselves. What deceives us, is the prodigious variety of our actions, joined to the habit which we catch at our birth, of confounding the voluntary and the free. We have been so often praised and blamed, and have so often praised and blamed others, that we contract an inveterate prejudice of believing that we and they will and act freely. But if there is no liberty, there is no action that merits either praise or blame; neither vice nor virtue, nothing that ought either to be rewarded or punished. What then is the distinction among men? The doing of good and the doing of ill! The doer of ill is one who must be destroyed, not punished. The doer of good is lucky, not virtuous. But though neither the doer of good or of ill be free, man is nevertheless a being to be modified; it is for this reason the doer of ill should be destroyed upon the scaffold. From thence the good effects of education, of pleasure, of grief, of grandeur, of poverty, &c.; from thence a philosophy full of pity, strongly attached to the good, nor more angry with the wicked, than with the whirlwind which fills one's eyes with dust. Strictly speaking, there is but one sort of causes, that is, physical causes. There is but one sort of necessity, which is the same for all beings. This is what reconciles me to humankind: it is for this reason I exhorted you to philanthropy. Adopt these principles if you think them good, or show me that they are bad. If you adopt them, they will reconcile *you* too with others and with yourself: you will neither be pleased nor angry with yourself for being what you are. Reproach others for nothing, and repent of nothing; this is the first step to wisdom. Besides this, all is prejudice and false philosophy."¹

The prevalence of the principles here so earnestly inculcated among the higher orders in France, at a period somewhat later in the history of the monarchy, may be judged of from the occasional allusions to them in the dramatic pieces then chiefly in request at Paris. In the *Mariage de Figaro* (the popularity of which was quite unexampled), the hero of

¹ Nearly to the same purpose, we are told by Mr. Belsham, that "the fallacious feeling of remorse is superseded by the doctrine of necessity." (*Edm.* p. 284.) And, again, "Remorse supposes free-will. It is of little or no use in moral discipline. In a degree, it is even pernicious." (*Ibid.* p. 406.)

Nor does the opinion of Hartley seem to have been different. "The doctrine of necessity has a tendency to abate all resentment against men. Since all they do against us is by the appointment of God, it is rebellion against him to be offended with them."

For the originals of the quotations from Grimm and Diderot, see Note (X.)

the piece, an intriguing valet in the service of a Spanish courtier, is introduced as, thus moralizing, in a soliloquy on his own free-agency and personal identity. Such an exhibition upon the English stage would have been universally censured as out of character and extravagant, or rather, would have been completely unintelligible to the crowds by which our theatres are filled.

“ Oh bizarre suite d'événemens ! Comment cela m'a-t-il arrivé ? Pourquoi ces choses et non pas d'autres ? Qui les a fixées sur ma tête ? Forcé de parcourir la route où je suis entré sans le savoir, comme j'en sortirai sans le vouloir, je l'ai jonchée d'autant de fleurs que ma gaieté me la permit ; encore je dis *ma* gaieté, sans savoir si elle est à moi plus que le reste, ni même qui est ce *moi* dont je m'occupe.”

That this soliloquy, though put into the mouth of Figaro, was meant as a picture of the philosophical jargon at that time affected by courtiers and men of the world, will not be doubted by those, who have attended to the importance of the *roles* commonly assigned to confidential valets in French comedies ; and to the habits of familiarity in which they are always represented as living with their masters. The sentiments which they are made to utter may, accordingly, be safely considered as but an echo of the lessons which they have learned from their superiors.¹

My anxiety to state, without any interruption, my remarks on some of the most important questions to which the attention of the public was called by the speculations of Locke, of Leibnitz, of Newton, and of Clarke, has led me, in various instances, to depart from the strict order of chronology. It is time for me, however, now to pause, and, before I proceed farther, to supply a few chasms in the foregoing sketch.

¹ A reflection of Voltaire's on the writings of Spinoza may, I think, be here quoted without impropriety. “ Vous êtes très confus Baruc Spinoza, mais êtes vous aussi dangereux qu'on le dit ? Je soutiens que non, et ma raison c'est que vous êtes confus, que vous avez écrit en mauvais Latin, et qu'il n'y a pas dix personnes en Europe qui vous lisent d'un bout à l'autre. Quel est l'auteur dangereux ? C'est celui qui est lu par les Oisifs de la Cour, et par les Dames.” (*Quest. sur l'Encyclop. Art. Dieu.*)

Had Voltaire kept this last remark steadily in view in his own writings, how many of those pages would he have cancelled which he has given to the world !

SECTION IV.

Of some Authors who have contributed, by their Critical or Historical Writings, to diffuse a Taste for Metaphysical Studies—Bayle—Fontenelle—Addison. Metaphysical Works of Berkeley.

AMONG the many eminent persons who were either driven from France, or who went into voluntary exile, in consequence of the revocation of the edict of Nantz, the most illustrious by far was Bayle;¹ who, fixing his residence in Holland, and availing himself, to the utmost extent, of the religious toleration then enjoyed in that country, diffused from thence, over Europe, a greater mass of accurate and curious information, accompanied by a more splendid display of acute and lively criticism, than had ever before come from the pen of a single individual.² Happy! if he had been able to restrain within due bounds his passion for sceptical and licentious discussion, and to respect the feelings of the wise and good, on topics connected with religion and morality. But, in the peculiar circumstances in which he was educated, combined with the seducing profession of a literary adventurer, to which his hard fortune condemned him, such a spirit of moderation was rather to be wished than expected.

When Bayle first appeared as an author, the opinions of the learned still continued to be divided between Aristotle and Descartes. A considerable number leaned, in secret, to the metaphysical creed of Spinoza and of Hobbes; while the clergy of the Roman Catholic and the Protestant churches, instead of uniting their efforts in defence of those truths which they professed in common, wasted their strength against each other in fruitless disputes and recriminations.

In the midst of these controversies, Bayle, keeping aloof as far as possible from all the parties, indulged his sceptical and ironical humour at the common expence of the various combatants. Unattached himself to any system, or, to speak more correctly, unfixed in his opinions on the most fundamental questions, he did not prosecute any particular study

¹ Born in 1647, died 1705.

² The erudition of Bayle is greatly undervalued by his antagonist Le Clerc. "Toutes les lumieres philosophiques de M. Bayle consistoient en quelque peu de Péripatétisme, qu'il avoit appris des Jésuites de Toulouse, et un peu de Cartésianisme, qu'il n'avoit jamais approfondi." (*Bibl. Choise, Tom. XII p. 106.*)

In the judgment of Gibbon, "Bayle's learning was chiefly confined to the Latin authors, and he had more of a certain multifarious reading than of real erudition. Le Clerc, his great antagonist, was as superior to him in that respect as inferior in every other" (*Extraits Raisonnés de mes Lectures, p. 62.*)

with sufficient perseverance to add materially to the stock of useful knowledge. The influence, however, of his writings on the taste and views of speculative men of all persuasions, has been so great, as to mark him out as one of the most conspicuous characters of his age; and I shall accordingly devote to him a larger space than may, at first sight, appear due to an author who has distinguished himself only by the extent of his historical researches, and by the sagacity and subtilty of his critical disquisitions.

We are informed by Bayle himself, that his favourite authors, during his youth, were Plutarch and Montaigne; and from *them*, it has been alleged by some of his biographers, he imbibed his first lessons of scepticism. In what manner the first of these writers should have contributed to inspire him with this temper of mind, is not very obvious. There is certainly no heathen philosopher or historian whose morality is more pure or elevated; and none who has drawn the line between superstition and religion with a nicer hand.¹ Pope has with perfect truth said of him, that "he abounds more in strokes of good nature than any other author;" to which it may be added, that he abounds also in touches of simple and exquisite *pathos*, seldom to be met with among the greatest painters of antiquity. In all these respects what a contrast does Bayle present to Plutarch!

Considering the share which Bayle ascribes to Montaigne's *Essays* in forming his literary taste, it is curious, that there is no separate article allotted to Montaigne in the *Historical and Critical Dictionary*. What is still more curious, there is more than one reference to this article, as if it actually existed; without any explanation of the omission (as far as I recollect) from the author or the publisher of the work. Some very interesting particulars, however, concerning Montaigne's life and writings, are scattered over the Dictionary, in the notices of other persons, with whom his name appeared to Bayle to have a sufficient connection to furnish an apology for a short episode.

It does not seem to me a very improbable conjecture, that Bayle had intended, and perhaps attempted, to write an account of Montaigne; and that he had experienced greater

¹ See, in particular, his account of the effects produced on the character of Pericles, by the sublime lessons of Anaxagoras.

Plutarch, it is true, had said before Bayle, that atheism is less pernicious than superstition; but how wide the difference between this paradox, as explained and qualified by the Greek philosopher, and as interpreted and applied in the *Reflections on the Comet*! Mr Addison himself seems to give his sanction to Plutarch's maxim in one of his papers on Cheerfulness. "An eminent Pagan writer has made a discourse to show, that the atheist who denies a God, does him less dishonour than the man who owns his being, but, at the same time, believes him to be cruel, hard to please, and terrible to human nature. For my own part, says he, I would rather it should be said of me, that there was never any such man as Plutarch, than that Plutarch was ill-natured, capricious, and inhuman" (*Spectator*, No. 494.)

difficulties than he was aware of, in the execution of his design. Notwithstanding their common tendency to Scepticism, no two characters were ever more strongly discriminated in their most prominent features; the doubts of the one resulting from the singular coldness of his moral temperament, combined with a subtlety and over-refinement in his habits of thinking, which rendered his ingenuity, acuteness, and erudition, more than a match for his good sense and sagacity;—the indecision of the other partaking more of the shrewd and soldier-like *étourderie* of Henry IV. when he exclaimed, after hearing two lawyers plead on opposite sides of the same question, “*Ventre St Gris! il me semble que tous les deux ont raison.*”

Independently of Bayle's constitutional bias towards Scepticism, some other motives, it is probable, conspired to induce him, in the composition of his *Dictionary*, to copy the spirit and tone of the old academic school. On these collateral motives a strong and not very favourable light is thrown by his own candid avowal in one of his letters. “In truth (says he to his correspondent Minutoli), it ought not to be thought strange, that so many persons should have inclined to Pyrrhonism; for of all things in the world it is the most convenient. You may dispute with impunity against every body you meet, without any dread of that vexatious argument which is addressed *ad hominem*. You are never afraid of a retort; for as you announce no opinion of your own, you are always ready to abandon those of others to the attacks of sophists of every description. In a word, you may dispute and jest on all subjects, without incurring any danger from the *lex talionis*.” It is amusing to think that the Pyrrhonism which Bayle himself has here so ingenuously accounted for, from motives of expediency and of literary cowardice, should have been mistaken by so many of his disciples for the sportive triumph of a superior intellect over the weaknesses and errors of human reason.*

* “En vérité, il ne faut pas trouver étrange que tant des gens aient donné dans le Pyrrhonisme. Car c'est la chose du monde la plus commode. Vous pouvez impunément disputer contre tous venans, et sans craindre ces argumens *ad hominem*, qui font quelquefois tant de peine. Vous ne craignez point la rétorsion; puisque ne soutenant rien, vous abandonnez de bon cœur à tous les sophismes et à tous les raisonnemens de la terre quelque opinion qu'elle soit. Vous n'êtes jamais obligé d'en venir à la défensive. En un mot vous contestez et vous daubez sur toutes choses tout votre saoul, sans craindre la peine du talion.” (*Oeuv. Div. de Bayle*, “IV” p. 537.)

* The estimate formed by Warburton of Bayle's character, both intellectual and moral, is candid and temperate. “A writer whose strength and clearness of reasoning can only be equalled by the gaiety, easiness, and delicacy, of his wit; who, pervading human nature with a glance, struck into the province of paradox, as an exercise for the restless vigour of his mind: who, with a soul superior to the sharpest attacks of fortune, and a heart practised to the best philosophy, had not yet enough of real greatness, to overcome that last foible of superior geniuses, the temptation of honour, which the academical exercise of wit is supposed to bring to its professors.” (*Divine Legation*.)

If there be anything objectionable in this panegyric, it is the unqualified praise bestowed on Bayle's wit,

The profession of Bayle, which made it an object to him to turn to account even the sweepings of his study, affords an additional explanation of the indigested mass of heterogeneous and inconsistent materials contained in his Dictionary. Had he adopted any one system exclusively, his work would have shrunk in its dimensions into a comparatively narrow compass.¹

When these different considerations are maturely weighed, the omission by Bayle of the article *Montaigne* will not be much regretted by the admirers of the Essays. It is extremely doubtful if Bayle would have been able to seize the true spirit of Montaigne's character; and, at any rate, it is not in the delineation of character that Bayle excels. His critical acumen, indeed, in the examination of opinions and arguments, is unrivalled; but his portraits of persons commonly exhibit only the coarser lineaments which obtrude themselves on the senses of ordinary observers; and seldom, if ever, evince that discriminating and divining eye, or that sympathetic penetration into the retirements of the heart, which lend to every touch of a master artist, the never to be mistaken expression of truth and nature.

which, though it seldom fails in copiousness, in poignancy, or in that grave argumentative irony, by which it is still more characteristically marked, is commonly as deficient in *gaiety* and *delicacy* as that of Warburton himself.

Leibnitz seems perfectly to have entered into the peculiar temper of his adversary Bayle, when he said of him, that "the only way to make Bayle write usefully, would be to attack him when he advances propositions that are sound and true; and to abstain from attacking him, when he says anything false or pernicious."

"Le vrai moyen de faire écrire utilement M. Bayle, ce seroit de l'attaquer, lorsqu'il écrit des bonnes choses et vraies, car ce seroit le moyen de le piquer pour continuer. Au lieu qu'il ne faudroit point l'attaquer quand il en dit de mauvaises, car cela l'engagera à en dire d'autres aussi mauvaises pour soutenir les premières." (Tom. VI. p. 273.)

Leibnitz elsewhere says of him: *Ubi bene, nemo melius.* (Tom. I. p. 257.)

¹ "The inequality of Bayle's voluminous works (says Gibbon) is explained by his alternately writing for himself, for the bookseller, and for posterity; and if a severe critic would reduce him to a single folio, that relic, like the books of the sybils, would become still more valuable." (Gibbon's *Mem.* p. 50.)

Mr Gibbon observes in another place, that, "if Bayle wrote his *Dictionary* to empty the various collections he had made, without any particular design, he could not have chosen a better plan. It permitted him everything, and obliged him to nothing. By the double freedom of a *Dictionary* and of Notes, he could pitch on what articles he pleased, and say what he pleased on those articles. (*Extraits Raisonnés de mes Lectures*, p. 64.)

"How could such a genius as Bayle," says the same author, "employ three or four pages, and a great apparatus of learning, to examine whether Achilles was fed with marrow only; whether it was the marrow of lions and stags, or that of lions only," &c. ? (*Ibid.* p. 66.)

For a long and interesting passage with respect to Bayle's history and character, see Gibbon's *Memoirs*, &c. Vol. I. pp. 49, 50, 51.

It furnishes some apology for the unsettled state of Bayle's opinions, that his habits of thinking were formed prior to the discoveries of the Newtonian School. Neither the vortices of Descartes, nor the monads and pre-established harmony of Leibnitz, were well calculated to inspire him with confidence in the powers of the human understanding; nor does he seem to have been led, either by taste or by genius, to the study of those exacter sciences in which Kepler, Galileo, and others, had, in the preceding age, made such splendid advances. In Geometry, he never proceeded beyond a few of the elementary propositions; and it is even said (although I apprehend with little probability) that his farther progress was stopped by some defect in his intellectual powers, which disqualified him for the successful prosecution of the study.

It is not unworthy of notice, that Bayle was the son of a Calvinist minister, and was destined by his father for his own profession; that during the course of his education in a college of Jesuits, he was converted to the Roman Catholic persuasion: and that finally he went to Geneva, where, if he was not recalled to the Protestant faith, he was at least most thoroughly reclaimed from the errors of popery.²

To these early fluctuations in his religious creed, may be ascribed his singularly accurate knowledge of controversial theology, and of the lives and tenets of the most distinguished divines of both churches,—a knowledge much more minute than a person of his talents could well be supposed to accumulate from the mere impulse of literary curiosity. In these respects he exhibits a striking resemblance to the historian of the *Decline and Fall of*

¹ For the benefit of education, the Protestants were tempted to risk their children in the Catholic Universities; and in the 22d year of his age young Bayle was seduced by the arts and arguments of the Jesuits of Toulouse. He remained about seventeen months in their hands a voluntary captive." (Gibson's *Misc. Works*, Vol. I. p. 49.)

² According to Gibbon, "the piety of Bayle was offended by the excessive worship of creatures; and the study of physics convinced him of the impossibility of transubstantiation, which is abundantly refuted by the testimony of our senses." (*Ibid.* p. 49.)

The same author, speaking of his own conversion from popery, observes (after allowing to his preceptor Mr Pavillard "a handsome share" of the honour), "that it was principally effected by his private reflections;" adding the following very curious acknowledgment: "I still remember my solitary transport at the discovery of a philosophical argument against the doctrine of Transubstantiation; that the text of Scripture, which seems to inculcate the real presence, is attested only by a single sense—our sight; while the real presence itself is disproved by three of our senses—the sight, the touch, and the taste." (*Ibid.* p. 58.) That this "philosophical argument" should have had any influence on the mind of Gibbon, even at the early period of life when he made "the discovery," would appear highly improbable, if the fact were not attested by himself; but as for Bayle, whose logical acumen was of a far harder and keener edge, it seems quite impossible to conceive, "that the study of physics" was at all necessary to open his eyes to the absurdity of the real presence; or that he would not at once have perceived the futility of appealing to our senses or to our reason, against an article of faith which professedly disclaims the authority of both.

the Roman Empire: Nor is the parallel between them less exact in the similar effects produced on their minds, by the polemical cast of their juvenile studies. Their common propensity to indulge in indecency is not so easily explicable. In neither does it seem to have originated in the habits of a dissolute youth; but in the wantonness of a polluted and distempered imagination. Bayle, it is well known, led the life of an anchorite;¹ and the licentiousness of his pen is, on that very account, the more reprehensible. But (everything considered) the grossness of Gibbon is certainly the more unaccountable, and perhaps the more unpardonable of the two.²

On the mischievous tendency of Bayle's work to unsettle the principles of superficial readers, and (what is worse) to damp the moral enthusiasm of youth, by shaking their faith in the reality of virtue, it would be superfluous to enlarge. The fact is indisputable, and is admitted even by his most partial admirers. It may not be equally useless to remark the benefits which (whether foreseen or not by the author, is of little consequence) have actually resulted to literature from his indefatigable labours. One thing will, I apprehend, be very generally granted in his favour, that, if he has taught men to suspend their judgment, he has taught them also to think and to reason for themselves; a lesson which appeared to a late philosophical divine of so great importance, as to suggest to him a doubt, whether it would not be better for authors to state nothing but *premises*, and to leave to their readers the task of forming their own *conclusions*.³ Nor can Bayle be candidly accused of often discovering a partiality for any particular sect of philosophers. He opposes Spinoza and Hobbes with the same spirit and ability, and apparently with the same good faith, with which he controverts the doctrines of Anaxagoras and of Plato. Even the ancient sceptics, for whose mode of philosophizing he might be supposed to have felt some degree of tenderness, are treated with as little ceremony as the most extravagant of the dogmatists. He has been often accused of a leaning to the most absurd of all systems,

¹ "Chaste dans ses mœurs, grave dans ses discours, sobre dans ses alimens, austère dans son genre de vie." (Portrait de Bayle par M. Saurin, dans son Sermon sur l'accord de la religion avec la politique.)

² In justice to Bayle, and also to Gibbon, it should be remembered, that over the most offensive passages in their works they have drawn the veil of the learned languages. It was reserved for the translators of the *Historical and Critical Dictionary* to tear this veil asunder, and to expose the indelicacy of their author to every curious eye. It is impossible to observe the patient industry and fidelity with which they have executed this part of their task without feelings of indignation and disgust. For such an outrage on taste and decorum, their tedious and feeble attacks on the Manicheism of Bayle offer but a poor compensation. Of all Bayle's suspected heresies, it was perhaps that which stood the least in need of a serious refutation; and, if the case had been otherwise, their incompetency to contend with such an adversary would have only injured the cause which they professed to defend.

³ See the preface to Bishop Butler's Sermons.

that of the Manicheans; and it must be owned, that there is none in defence of which he has so often and so ably¹ exerted his talents; but it is easy to perceive, that, when he does so, it is not from any serious faith which he attaches to it (perhaps the contrary supposition would be nearer the truth), but from the peculiarly ample field which it opened for the display of his controversial subtlety, and of his inexhaustible stores of miscellaneous information.² In one passage he has pronounced with a tone of decision which he seldom assumes, that "it is absurd, indefensible, and inconsistent with the regularity and order of the universe; that the arguments in favour of it are liable to be retorted; and that, granting it to be true, it would afford no solution of the difficulties in question."³ The apparent zeal with which, on various occasions, he has taken up its defence, may, I think, be reasonably accounted for, by the favourable opportunity it afforded him of measuring his logical powers with those of Leibnitz.⁴

To these considerations it may be added, that, in consequence of the progress of the sciences since Bayle's time, the unlimited scepticism commonly, and perhaps justly imputed to him, is much less likely to mislead than it was a century ago; while the value of his researches, and of his critical reflections, becomes every day more conspicuous, in proportion as more enlarged views of nature, and of human affairs, enable us to combine together that mass of

¹ Particularly in the article entitled *Paulicians*.

² One of the earliest as well as the ablest of those who undertook a reply to the passages in Bayle which seem to favour Manichæism, candidly acquits him of any serious design to recommend that system to his readers. "En répondant aux objections Manichéennes, je ne prétends faire aucun tort à M. Bayle: qui je ne soupçonne nullement de les favoriser. Je suis persuadé qu'il n'a pris la liberté philosophique de dire, en bien des rencontres, le pour et le contre, sans rien dissimuler, que pour donner de l'exercice à ceux que entendent les matières qu'il traite, et non pour favoriser ceux dont il explique les raisons." (*Parrhasiana, ou Pensées Diverses*, p. 302, par M. Le Clerc, Amsterdam, 1699.)

³ See the illustration upon the Sceptics at the end of the Dictionary.

⁴ This supposition may be thought inconsistent with the well known fact, that the Theodicée of Leibnitz was not published till after the death of Bayle. But it must be recollected, that Bayle had previously entered the lists with Leibnitz in the article *Rorarius*, where he had urged some very acute and forcible objections against the scheme of *pre-established harmony*; a scheme which leads so naturally and obviously to that of optimism, that it was not difficult to foresee what ground Leibnitz was likely to take in defending his principles. The great aim of Bayle seems to have been to provoke Leibnitz to unfold the whole of his system and of its necessary consequences; well knowing what advantages in the management of such a controversy would be on the side of the assailant.

The tribute paid by Leibnitz to the memory of his illustrious antagonist deserves to be quoted. "Sperandum est, Bælium luminibus illis nunc circumdari, quod terris negatum est: cum credibile sit, bonam voluntatem ei nequaquam defuisse."

"Candidus insuetum miratur limen Olympi,

* Sub pedibusque videt nubes et sidera Daphnia."

rich but indigested materials, in the compilation of which his own opinions and principles seem to have been totally lost. Neither comprehension, indeed, nor generalization, nor metaphysical depth,¹ are to be numbered among the characteristical attributes of his genius. Far less does he ever anticipate, by the moral lights of the soul, the slow and hesitating decisions of the understanding; or touch with a privileged hand those mysterious chords to which all the social sympathies of our frame are responsive. Had his ambition, however, been more exalted, or his philanthropy more warm and diffusive, he would probably have attempted less than he actually accomplished; nor would he have stooped to enjoy that undisputed pre-eminence which the public voice has now unanimously assigned him, among those inestimable though often ill requited authors, whom Johnson has called "the pioneers of literature."

The suspense of judgment which Bayle's *Dictionary* inspires with respect to *facts*, is, perhaps, still more useful than that which it encourages in matters of abstract reasoning. Fontenelle certainly went much too far, when he said of history, that it was only a collection of *Fables Convencues*;—a most significant and happy phrase, to which I am sorry that I cannot do justice in an English version. But, though Fontenelle pushed his maxim to an extreme, there is yet a great deal of important truth in the remark; and of this I believe every person's conviction will be stronger, in proportion as his knowledge of men and of books is profound and extensive.

Of the various lessons of historical scepticism to be learned from Bayle, there is none more practically valuable (more especially in such revolutionary times as we have witnessed) than that which relates to the biographical portraits of distinguished persons, when drawn by their theological and political opponents. In illustration of this, I have only to refer to the copious and instructive extracts which he has produced from Roman Catholic writers, concerning the lives, and still more concerning the deaths, of Luther, Knox,² Buchanan, and various other leaders or partizans of the Reformation. It would be impossible for any well-informed Protestant to read these extracts, without indulging a smile at their incredible absurdity, if every feeling of levity were not lost in a sentiment of deep indignation at the effrontery and falsehood of their authors. In stating this observation, I have taken my examples from Roman Catholic libellers, without any illiberal prejudices against the members of that church. The injustice done by Pro-

¹ I speak of that metaphysical *depth* which is the exclusive result of what Newton called *Patient Thinking*. In logical quickness, and metaphysical subtlety, Bayle has never been surpassed.

² See Note (Y.)

testants to some of the conscientious defenders of the old faith has been, in all probability, equally great; but this we have no opportunity of ascertaining here, by the same direct evidence to which we can fortunately appeal, in vindication of the three characters mentioned above. With the history of *two* of them every person in this country is fully acquainted; and I have purposely selected them in preference to others, as their *names* alone are sufficient to cover with disgrace the memory of their calumniators.¹

A few years before the death of Bayle, Fontenelle began to attract the notice of Europe.² I class them together on account of the mighty influence of both on the literary taste of their contemporaries; an influence in neither case founded on any claims to original genius, or to important improvements; but on the attractions which they possessed in common (though in very different ways) as popular writers; and on the easy and agreeable access which their works opened to the opinions and speculations of the learned. Nor do I depart so far, as might at first be supposed, from the order of chronology, in passing from the one to the other. For though Fontenelle survived almost to our own times (having very nearly completed a century at the time of his death), the interval between his birth and that of Bayle was only ten years, and he had actually published several volumes, both in prose and verse, before the *Dictionary* of Bayle appeared.

But my chief reason for connecting Fontenelle rather with the contemporaries of his youth than with those of his old age is, that, during the latter part of his life, he was left far behind in his philosophical creed (for he never renounced his faith as a Cartesian³) by

¹ Of all Bayle's works, "the most useful and the least sceptical," according to Gibbon, "is his *Commentaire Philosophique* on these words of the Gospel, *Compel them to come in.*"

The great object of this commentary is to establish the general principles of Toleration, and to remonstrate with the members of Protestant churches on the inconsistency of their refusing to those they esteem heretics, the same indulgence which they claim for themselves in Catholic countries. The work is diffuse and rambling, like all Bayle's compositions; but the matter is excellent, and well deserves the praise which Gibbon has bestowed on it.

² Bayle died in 1706. Fontenelle's first work in prose (the *Dialogues of the Dead*) was published as early as 1683, and was quickly followed by his *Conversations on the Plurality of Worlds*.

³ Excepting on a few metaphysical points. The chief of these were, the question concerning the origin of our ideas, and that relating to the nature of the lower animals. On the former of these subject he has said explicitly: "L'Ancienne Philosophie n'a pas toujours eu tort. Elle a soutenu que tout ce qui étoit dans l'esprit avoit passé par les sens, et nous n'avons pas mal fait de conserver cela d'elle." (*Fragment of an intended Treatise on the Human Mind.*) On another occasion, he states his own opinion on this point, in language coinciding exactly with that of Gassendi. "A force d'opérer sur les premières idées formées par les sens, d'y ajouter, d'en retrancher, de les rendre de particulières universelles, d'universelles plus universelles encore, l'esprit les rend si différentes de ce qu'elles étoit d'abord qu'on a quelquefois peine à reconnaître leur origine. Cependant qui voudra

those very pupils to whose minds he had given so powerful an impulse, and whom he had so long taught by his example, the art (till then unknown in modern times) of blending the truths of the severer sciences with the lights and graces of eloquence. Even this *eloquence*, once so much admired, had ceased, before his death, to be regarded as a model, and was fast giving way to the purer and more manly taste in writing, recommended by the precepts, and exemplified in the historical compositions of Voltaire.

Fontenelle was a nephew of the great Corneille; but his genius was, in many respects, very strongly contrasted with that of the author of the *Cid*. Of this he has himself enabled us to judge by the feeble and unsuccessful attempts in dramatic poetry, by which he was first known to the world. In these, indeed, as in all his productions, there is an abundance of ingenuity, of elegance, and of courtly refinement; but not the faintest vestige of the *mens divinator*, or that of sympathy with the higher and nobler passions which enabled Corneille to reanimate and to reproduce on the stage the heroes of ancient Rome. The circumstance, however, which more peculiarly marks and distinguishes his writings, is the *French mould* in which education and habit seem to have recast all the original features of his mind;—identifying, at the same time, so perfectly the impressions of art with the workmanship of nature, that one would think the *PARISIAN*, as well as the *MAN*, had started fresh and finished from her creative hand. Even in his *Conversations on the Plurality of Worlds*, the dry discussions with the Marchioness about the now forgotten vortices of Descartes are enlivened throughout by a never-failing spirit of light and national gallantry, which will for ever render them an amusing picture of the manners of the times, and of the character of the author. The gallantry, it must be owned, is often strained and affected; but the affectation sits so well on Fontenelle, that he would appear less easy and graceful without it.

The only other production of Fontenelle's youth which deserves to be noticed is his *History of Oracles*; a work of which the aim was, to combat the popular belief that the oracles of antiquity were uttered by evil spirits, and that all these spirits became dumb at the moment of the Christian era. To this work Fontenelle contributed little more than the agreeable and lively form in which he gave it to the world; the chief materials being derived from a dull and prolix dissertation on the same subject, by a learned Dutchman. The publication excited a keen opposition among divines, both Catholic and Protestant; and, in particular, gave occasion to a very angry, and (it is said) not contemptible criticism,

prendre le fil et le suivre exactement, retournera toujours de l'idée la plus sublime et la plus élevée, à quelque idée sensible et grossière."

from a member of the Society of Jesuits.¹ It is mentioned by La Harpe, as an illustration of the rapid change in men's opinions which took place during Fontenelle's life, that a book which, in his youth, was censured for its impiety, was regarded before his death as a proof of his respect for religion.

The most solid basis of Fontenelle's fame is his *History of the Academy of Sciences*, and his *Eloges of the Academicians*. Both of these works, but more especially the latter, possess, in an eminent degree, all the charms of his former publications, and are written in a much simpler and better taste than any of the others. The materials, besides, are of inestimable value, as succinct and authentic records of one of the most memorable periods in the history of the human mind; and are distinguished by a rare impartiality towards the illustrious dead, of all countries, and of all persuasions. The philosophical reflections, too, which the author has most skilfully interwoven with his literary details, discover a depth and justness of understanding far beyond the promise of his juvenile Essays; and afford many proofs of the soundness of his logical views,² as well as of his acute and fine discrimination of the varieties and shades of character, both intellectual and moral.

The chief and distinguishing merit of Fontenelle, as the historian of the Academy, is the happy facility with which he adapts the most abstruse and refined speculations to the comprehension of ordinary readers. Nor is this excellence purchased by any sacrifice of scientific precision. What he aims at is nothing more than an outline; but this outline is always executed with the firm and exact hand of a master. "When employed in com-

¹ To this criticism, the only reply made by Fontenelle was a single sentence, which he addressed to a *Journalist* who had urged him to take up arms in his own defence. "Je laisserai mon censeur jouir en paix de son triomphe; je consens que le diable ait été prophète, puisque le Jesuite le veut, et qu'il croit cela plus orthodoxe." (D'Alembert, *Eloge de la Motte*.) We are told by D'Alembert, that the silence of Fontenelle, on this occasion, was owing to the advice of La Motte. "Fontenelle bien tenté de terrasser son adversaire par la facilité qu'il y trouvoit, fut retenu par les avis prudens de la Motte; cet ami lui fit craindre de s'aliéner par sa réponse une société qui s'appeloit *Légion*, quand on avoit affaire au dernier de ses membres." The advice merits the attention of philosophers in all countries, for the spirit of Jesuitism is not confined to the Church of Rome.

² An instance of this which happens at present to recur to my memory, may serve to illustrate and to confirm the above remark. It is unnecessary to point out its coincidence with the views which gave birth to the new nomenclature in chemistry.

"If languages had been the work of philosophers, they might certainly be more easily learned. Philosophers would have established everywhere a systematical uniformity, which would have proved a safe and infallible guide; and the manner of forming a derivative word, would, as a necessary consequence, have suggested its signification. The uncivilized nations, who are the first authors of languages, fell naturally into that notion with respect to certain terminations, all of which have some common property or virtue; but that advantage, unknown to those who had it in their hands, was not carried to a sufficient extent."

position (he has somewhere said) my first concern is to be certain that I myself understand what I am about to write;" and on the utility of this practice every page of his *Historical Memoirs* may serve as a comment.¹

As a writer of *Eloges*, he has not been equalled (if I may be allowed to hazard my own opinion) by any of his countrymen. Some of those, indeed, by D'Alembert and by Condorcet, manifest powers of a far higher order than belonged to Fontenelle; but neither of these writers possessed Fontenelle's incommunicable art of interesting the curiosity and the feelings of his readers in the fortunes of every individual whom he honoured by his notice. In this art it is not improbable that they might have succeeded better had they imitated Fontenelle's self-denial in sacrificing the fleeting praise of brilliant colouring, to the fidelity and lasting effect of their portraits; a self-denial which in *him* was the more meritorious, as his great ambition plainly was to unite the reputation of a *bel-esprit* with that of a philosopher. A justly celebrated academician of the present times (M. Cuvier), who has evidently adopted Fontenelle as his model, has accordingly given an interest and truth to his *Eloges* which the public had long ceased to expect in that species of composition.²

But the principal charm of Fontenelle's *Eloges* arises from the pleasing pictures which they everywhere present of genius and learning in the scenes of domestic life. In this respect, it has been justly said of them by M. Suard,³ that "they form the noblest monument ever raised to the glory of the sciences and of letters." Fontenelle himself, in his

¹ From this praise, however, must be excepted, the mysterious jargon in which (after the example of some of his contemporaries) he has indulged himself in speaking of the geometry and calculus of infinites. "Nous le disons avec peine (says D'Alembert), et sans vouloir, outrager les manes d'un homme célèbre qui n'est plus, il n'y a peut-être point d'ouvrage où l'on trouve des preuves plus fréquentes de l'abus de la métaphysique, que dans l'ouvrage très connu de M. Fontenelle, qui a pour titre *Elémens de la Géométrie de l'infini*; ouvrage dont la lecture est d'autant plus dangereuse aux jeunes géomètres que l'auteur y présente les sophismes avec une sorte d'élégance et de grace, dont le sujet ne paroissoit pas susceptible." (*Mélanges*, &c. Tom. V. p. 264.)

² D'Alembert, in his ingenious parallel of Fontenelle and La Motte, has made a remark on Fontenelle's style when he aims at simplicity, of the justness of which *French* critics alone are competent judges. "L'un et l'autre ont écrit en prose avec beaucoup de clarté, d'élégance, de simplicité même; mais La Motte avec une simplicité plus naturelle, et Fontenelle avec une simplicité plus étudiée: Car la simplicité peut l'être, et dès lors elle devient manière, et cesse d'être modèle." An idea very similar to this is happily expressed by Congreve, in his portrait of *Amoret*:

Coquet and Coy at once her air,
Both studied, though both seem neglected;
Careless she is with artful care,
Affecting to seem unaffected.

³ *Notice sur la Vie et les Ecrits du Docteur Robertson.* (Paris, 1817.)

Eloge of Varignon, after remarking, that in *him* the simplicity of his character was only equalled by the superiority of his talents, finely adds, "I have already bestowed so often the same praise on other members of this Academy, that it may be doubted whether it is not less due to the individuals, than to the sciences which they cultivated in common." What a proud reply does this reflection afford to the Machiavellian calumniators of philosophy!

The influence of these two works of Fontenelle on the studies of the rising generation all over Europe, can be conceived by those alone who have compared them with similar productions of an earlier date. Sciences which had long been immured in colleges and cloisters, began at length to breathe the ventilated and wholesome air of social life. The union of philosophy and the fine arts, so much boasted of in the schools of ancient Greece, seemed to promise a speedy and invigorated revival. Geometry, Mechanics, Physics, Metaphysics, and Morals, became objects of pursuit in courts and in camps; the accomplishments of a scholar grew more and more into repute among the other characteristics of a gentleman: and (what was of still greater importance to the world) the learned discovered the secret of cultivating the graces of writing, as a necessary passport to truth, in a refined but dissipated age.

Nor was this change of manners confined to one of the sexes. The other sex, to whom nature has entrusted the first developement of our intellectual and moral powers, and who may, therefore, be regarded as the chief *medium* through which the progress of the mind is continued from generation to generation, shared also largely in the general improvement. Fontenelle aspired above all things to be the philosopher of the Parisian circles; and certainly contributed not a little to diffuse a taste for useful knowledge among women of all conditions in France, by bringing it into vogue among the higher classes. A reformation so great and so sudden could not possibly take place, without giving birth to much affectation, extravagance, and folly; but the whole analogy of human affairs encourages us to hope, that the inconveniencies and evils connected with it will be partial and temporary, and its beneficial results permanent and progressive.¹

¹ Among the various other respects in which Fontenelle contributed to the intellectual improvement of his countrymen, it ought to be mentioned, that he was one of the first writers in France who diverted the attention of metaphysicians from the old topics of scholastic discussion, to a philosophical investigation of the principles of the fine arts. Various original hints upon these subjects are scattered over his works; but the most favourable specimen of his talents for this very delicate species of analysis are to be found in his *Dissertation on Pastorals*, and in his *Theory concerning the Delight we derive from Tragedy*.^{*} His

^{*} In the judgment of Mr. Hume, "there is not a finer piece of criticism than Fontenelle's *Dissertation on Pastorals*; in which, by a number of reflections and philosophical reasonings, he endeavours to fix the just medium between Simplicity and Refinement, which is suitable to that species of poetry."

Among the various moral defects imputed to Fontenelle, that of a complete apathy and insensibility to all concerns but his own is by far the most prominent. A letter of the Baron de Grimm, written immediately after Fontenelle's death, but not published till lately, has given a new circulation in this country to some anecdotes injurious to his memory, which had long ago fallen into oblivion or contempt in France. The authority, however, of this adventurer, who earned his subsistence by collecting and retailing, for the amusement of a German Prince, the literary scandal of Paris, is not much to be relied on in estimating a character with which he does not appear to have had any opportunity of becoming personally acquainted; more especially as, during Fontenelle's long decline, the great majority of men of letters in France were disposed to throw his merits into the shade, as an acceptable homage to the rising and more dazzling glories of Voltaire.¹ It is in the

speculations, indeed, are not always just and satisfactory; but they are seldom deficient in novelty or refinement. Their principal fault, perhaps, arises from the author's disposition to carry his refinements too far; in consequence of which, his theories become chargeable with that sort of sublimated ingenuity which the French without *Alambiqué* expresses more precisely and forcibly than any word in our language.

Something of the same philosophical spirit may be traced in Fenelon's *Dialogues on Eloquence*, and in his *Lettre on Rhetoric and Poetry*. The former of these treatises, besides its merits as a speculative discussion, contains various practical hints, well entitled to the attention of those who aspire to eminence as public speakers; and of which the most apparently trifling claim some regard, as the results of the author's reflections upon an art which few ever practised with greater success.

Let me add, that both of these eminent men (who may be regarded as the fathers of philosophical criticism in France) were zealous partizans and admirers of the Cartesian metaphysics. It is this critical branch of metaphysical science which, in my opinion, has been most successfully cultivated by French writers; although too many of them have been infected (after the example of Fontenelle) with the disease of sickly and of hyper-metaphysical subtlety.

From this censure, however, must be excepted the Abbé Dubos, whose *Critical Reflections on Poetry and Painting* is one of the most agreeable and instructive works that can be put into the hands of youth. Few books are better calculated for leading their minds gradually from literature to philosophy. The author's theories, if not always profound or just, are in general marked with good sense as well as with ingenuity; and the subjects to which they relate are so peculiarly attractive, as to fix the attention even of those readers who have but little relish for speculative discussions. "Ce qui fait la bonté de cet ouvrage (says Voltaire) c'est qu'il n'y a que peu d'erreurs, et beaucoup de réflexions vraies, nouvelles, et profondes. Il manque cependant d'ordre et sur-tout de précision; il auroit pu être écrit avec plus de feu, de grace et d'élégance; mais l'écrivain pense et fait penser." (*Siccle de Louis XIV.*)

¹ As to Voltaire himself, it must be mentioned, to his honour, that though there seems never to have been much cordiality between him and Fontenelle, he had yet the magnanimity to give a place to this Nestor of French literature in his catalogue of the eminent persons who adorned the reign of Louis XIV.; a tribute of respect the more flattering, as it is the single instance in which he has departed from his general rule of excluding from his list the names of all his living contemporaries. Even Fontenelle's most devoted admirers ought to be satisfied with the liberality of Voltaire's eulogy, in which, after pronouncing Fontenelle "the most universal genius which the age of Louis XIV. had produced," he thus sums up his merits as author: "Enfin on l'a re-

Academical Memoirs of D'Alembert and Condorcet (neither of whom can be suspected of any unjust prejudice against Voltaire, but who were both too candid to sacrifice truth to party feelings) that we ought to search for Fontenelle's real portrait:¹ Or rather (if it be true, as Dr Hutcheson has somewhere remarked, that "men have commonly the good or bad qualities which they ascribe to mankind") the most faithful *Eloge* on Fontenelle himself is to be found in those which he has pronounced upon others.

That the character of Fontenelle would have been more amiable and interesting, had his virtues been less the result of cold and prudent calculation, it is impossible to dispute. But his conduct through life was pure and blameless; and the happy serenity of his temper, which prolonged his life till he had almost completed his hundredth year, served as the best comment on the spirit of that mild and benevolent philosophy, of which he had laboured so long to extend the empire.

It is a circumstance almost singular in his history, that, since the period of his death, his reputation, both as a man and as an author, has been gradually rising. The fact has been as remarkably the reverse with most of those who have calumniated his memory.

While the circle of mental cultivation was thus rapidly widening in France, a similar progress was taking place, upon a larger scale, and under still more favourable circumstances, in England. To this progress nothing contributed more powerfully than the periodical papers published under various titles by Addison² and his associates. The

gardé comme le premier des hommes dans l'art nouveau de repandre de la lumiere et des graces sur les sciences abstraites, et il a eu du merite dans tous les autres genres qu'il a traités. Tant de talens ont été soutenus par la connoissance des langues et de l'histoire, et il a été sans contredit au-dessus de tous les savans qui n'ont pas eu le don de l'invention."

¹ Condorcet has said expressly, that his apathy was confined entirely to what regarded himself, and that he was always an active, though frequently a concealed friend, where his good offices could be useful to those who deserved them. "On a cru Fontenelle insensible, parce que sachant maîtriser les mouvemens de son ame il se conduisoit d'après son esprit, toujours juste et toujours sage. D'ailleurs, il avoit consenti sans peine à conserver cette réputation d'insensibilité; il avoit souffert les plaisanteries de ses sociétés sur sa froideur, sans chercher à les détromper, parce que, bien sur que les vraies amis n'en seroit pas la dupe, il voyoit dans cette réputation un moyen commode de se délivrer des indifferens sans blesser leur amour propre." (*Eloge de Fontenelle, par Condorcet.*)

Many of Fontenelle's sayings, the import of which must have depended entirely on circumstances of time and place unknown to us, have been absurdly quoted to his disadvantage, in their literal and most obvious acceptance. "I hate war (said he), for it spoils conversation." Can any just inference be drawn from the levity of this convivial sally, against the humanity of the person who uttered it? Or rather, when connected with the characteristic *finesse* of Fontenelle's wit, does it not lead to a conclusion precisely opposite?

² Born in 1672, died in 1719.

effect of these in reclaiming the public taste from the licentiousness and grossness introduced into England at the period of the Restoration; in recommending the most serious and important truths by the united attractions of wit, humour, imagination, and eloquence; and, above all, in counteracting those superstitious terrors which the weak and ignorant are so apt to mistake for religious and moral impressions—has been remarked by numberless critics, and is acknowledged even by those who felt no undue partiality in favour of the authors.¹ Some of the papers of Addison, however, are of an order still higher, and bear marks of a mind which, if early and steadily turned to philosophical pursuits, might have accomplished much more than it ventured to undertake. His frequent references to the *Essay on Human Understanding*, and the high encomiums with which they are always accompanied, show how successfully he had entered into the spirit of that work; and how completely he was aware of the importance of its object. The popular nature of his publications, indeed, which rendered it necessary for him to avoid everything that might savour of scholastic or of metaphysical discussion, has left us no means of estimating his philosophical depth, but what are afforded by the *results* of his thoughts on the particular topics which he has occasion to allude to, and by some of his incidental comments on the scientific merits of preceding authors. But these means are sufficiently ample to justify a very high opinion of his sound and unprejudiced judgment, as well as of the extent and correctness of his literary information. Of his powers as a logical reasoner he has not enabled us to form an estimate; but none of his contemporaries seem to have been more completely tinctured with all that is most valuable in the metaphysical and ethical systems of his time.²

But what chiefly entitles the name of Addison to a place in this Discourse, is his *Essays on the Pleasures of Imagination*; the first attempt in England to investigate the principles of the fine arts; and an attempt which, notwithstanding many defects in the

¹ See Pope's *Imitations of Horace*, Book II. Epistle I. "Unhappy Dryden," &c. &c.

² I quote the following passage from Addison, *not* as a specimen of his metaphysical acumen, but as a proof of his good sense in divining and obviating a difficulty which I believe most persons will acknowledge occurred to themselves when they first entered on metaphysical studies:—

"Although we divide the soul into several powers and faculties, there is no such division in the soul itself, since it is the *whole soul* that remembers, understands, wills, or imagines. Our manner of considering the memory, understanding, will, imagination, and the like faculties, is for the better enabling us to express ourselves in such abstracted subjects of speculation, not that there is any such division in the soul itself." In another part of the same paper, Addison observes, that "what we call the faculties of the soul are only the different ways or modes in which the soul can exert herself." (*Spectator*, No. 600.)

For some important remarks on the words *Powers* and *Faculties*, as applied to the Mind, see Locke, B. II. Ch. xxi. § 20.

execution, is entitled to the praise of having struck out a new avenue to the study of the human mind, more alluring than any which had been opened before. In this respect, it forms a most important supplement to Locke's *Survey of the Intellectual Powers*; and it has, accordingly, served as a text, on which the greater part of Locke's disciples have been eager to offer their comments and their corrections. The progress made by some of these in exploring this interesting region has been great; but let not Addison be defrauded of his claims as a discoverer.

Similar remarks may be extended to the hints suggested by Addison on Wit, on Humour, and on the Causes of Laughter. It cannot, indeed, be said of him, that he exhausted any one of these subjects; but he had at least the merit of starting them as Problems for the consideration of philosophers; nor would it be easy to name among his successors, a single writer who has made so important a step towards their solution, as the original proposer.

The philosophy of the papers to which the foregoing observations refer, has been pronounced to be slight and superficial, by a crowd of modern metaphysicians who were but ill entitled to erect themselves into judges on such a question.¹ The singular simplicity and perspicuity of Addison's style have contributed much to the prevalence of this prejudice. Eager for the instruction, and unambitious of the admiration of the multitude, he everywhere studies to bring himself down to their level; and even when he thinks with the greatest originality, and writes with the most inimitable felicity, so easily do we enter into the train of his ideas, that we can hardly persuade ourselves that we could not have thought and written in the same manner. He has somewhere said of "fine writing," that it "consists of sentiments which are natural, without being obvious:" and his definition has been applauded by Hume, as at once concise and just. Of the thing defined, his own periodical essays exhibit the most perfect examples.

To this simplicity and perspicuity, the wide circulation which his works have so long maintained among all classes of readers, is in a great measure to be ascribed. His periods are not constructed, like those of Johnson, to "elevate and surprise," by filling the ear and dazzling the fancy; but we close his volumes with greater reluctance, and return to the perusal of them with far greater alacrity. Franklin, whose fugitive publications on political topics have had so extraordinary an influence on public opinion, both in the Old and New Worlds, tells us that his style in writing was formed upon the model of Ad-

¹ See Note (Z.)

dison: Nor do I know anything in the history of his life which does more honour to his shrewdness and sagacity. The copyist, indeed, did not possess the gifted hand of his master,—*Museo contingens cuncta lepore*;—but such is the effect of his plain and seemingly artless manner, that the most profound conclusions of political economy assume, in his hands, the appearance of indisputable truths; and some of them, which had been formerly confined to the speculative few, are already current in every country of Europe, as proverbial maxims.¹

To touch (however slightly) on Addison's other merits, as a critic, as a wit, as a speculative politician, and, above all, as a moralist, would lead me completely astray from my present object. It will not be equally foreign to it to quote the two following short passages, which, though not strictly *metaphysical*, are, both of them, the result of metaphysical habits of thinking, and bear a stronger resemblance than anything I recollect among the wits of Queen Anne's reign, to the best philosophy of the present age. They approach, indeed, very nearly to the philosophy of Turgot and of Smith.

"Among other excellent arguments for the immortality of the soul, there is one drawn from the perpetual progress of the soul to its perfection, without a possibility of ever arriving at it; which is a hint that I do not remember to have seen opened and improved by others who have written on this subject, though it seems to me to carry a great weight with it. A brute arrives at a point of perfection that he can never pass. In a few years he has all the endowments he is capable of; and were he to live ten thousand more, would be the same thing he is at present. Were a human soul thus at a stand in her accomplishments, were her faculties to be full-blown, and incapable of farther enlargement, I would imagine it might fall away insensibly, and drop at once into a state of annihilation. But can we believe a thinking being, that is in a perpetual progress of improvement, and travelling on from perfection to perfection, after having just looked abroad into the works of its Creator, and made a few discoveries of his infinite goodness, wisdom, and power, must perish at her first setting out, and in the very beginning of her inquiries?"²

The philosophy of the other passage is not unworthy of the author of the *Wealth of Nations*. The *thought* may be traced to earlier writers, but certainly it was never before

¹ The expressions "*Laissez nous faire*," and "*pas trop gouverner*," which comprise, in a few words, two of the most important lessons of Political wisdom, are indebted chiefly for their extensive circulation to the short and luminous comments of Franklin. (See his *Political Fragments*, § 4.)

² This argument has been prosecuted with great ingenuity and force of reasoning (blended, however, with some of the peculiarities of his Berkeleian metaphysics) by the late Dr. James Hutton. (See his *Investigation of the Principles of Knowledge*, Vol. III. p. 195, et seq. Edin. 1794.)

presented with the same fulness and liveliness of illustration; nor do I know, in all Addison's works, a finer instance of his solicitude for the improvement of his fair readers, than the address with which he here insinuates one of the sublimest moral lessons, while apparently aiming only to amuse them with the geographical history of the muff and the tippet.

"Nature seems to have taken a particular care to disseminate her blessings among the different regions of the world, with an eye to the mutual intercourse and traffic among mankind; that the natives of the several parts of the globe might have a kind of dependence upon one another, and be united together by their common interest. Almost every *degree* produces something peculiar to it. The food often grows in one country, and the sauce in another. The fruits of Portugal are corrected by the products of Barbadoes; the infusion of a China plant, sweetened with the pith of an Indian cane. The Philippine Islands give a flavour to our European bowls. The single dress of a woman of quality is often the product of a hundred climates. The muff and the fan come together from the opposite ends of the earth. The scarf is sent from the torrid zone, and the tippet from beneath the pole. The brocade petticoat rises out of the mines of Peru, and the diamond necklace out of the bowels of Indostan."

But I must not dwell longer on the fascinating pages of Addison. Allow me only, before I close them, to contrast the last extract with a remark of Voltaire, which, shallow and contemptible as it is, occurs more than once, both in verse and in prose, in his voluminous writings.

Il murt a Moka, dans le sable Arabique,
Ce Caffé nécessaire aux pays des frimats;
Il met la Fièvre en nos climats,
Et le remède en Amérique.

(*Épître au Roi du Prusse*, 1750.)

And yet Voltaire is admired as a philosopher by many who will smile to hear this title bestowed upon Addison!

It is observed by Akenside, in one of the notes to the *Pleasures of Imagination*, that "Philosophy and the Fine Arts can hardly be conceived at a greater distance from each other than at the Revolution, when Locke stood at the head of one party, and Dryden of the other." He observes, also, that "a very great progress towards their re-union had been made within these few years." To this progress the chief impulse was undoubtedly given by Addison and Shaftesbury.

Notwithstanding, however, my strong partiality for the former of these writers, I should be truly sorry to think, with Mr. Hume, that "Addison will be read with plea-

sure when Locke shall be *entirely forgotten*." (*Essay on the Different Species of Philosophy*.)

A few years before the commencement of these periodical works, a memorable accession was made to metaphysical science, by the publication of Berkeley's *New Theory of Vision*; and of his *Principles of Human Knowledge*. Possessed of a mind which, however inferior to that of Locke in depth of reflection and in soundness of judgment, was fully its equal in logical acuteness and invention, and in learning, fancy, and taste, far its superior, —Berkeley was singularly fitted to promote that re-union of Philosophy and of the Fine Arts which is so essential to the prosperity of both. Locke, we are told, despised poetry; and we know from one of his own letters, that, among our English poets, his favourite author was Sir Richard Blackmore. Berkeley, on the other hand, courted the society of all, from whose conversation and manners he could hope to add to the embellishments of his genius; and although himself a decided and High Church Tory,¹ lived in the habits of friendship with Steele and Addison, as well as with Pope and Swift. Pope's admiration of him seems to have risen to a sort of enthusiasm. He yielded to Berkeley's decision on a very delicate question relating to the exordium of the *Essay on Man*; and on his moral qualities he has bestowed the highest and most unqualified eulogy to be found in his writings.

" Even in a Bishop I can spy desert,
Secker is decent; Rundle has a heart;
Manners with candour are to Benson given,
To Berkeley every virtue under Heaven."

With these intellectual and moral endowments, admired and blazoned as they were by the most distinguished wits of his age, it is not surprising that Berkeley should have given a popularity and fashion to metaphysical pursuits, which they had never before acquired in England. Nor was this popularity diminished by the boldness of some of his paradoxes: on the contrary, it was in no small degree the *effect* of them; the great bulk of mankind being always prone to mistake a singularity or eccentricity of thinking, for the originality of a creative genius.

¹ See a volume of Sermons, preached in the chapel of Trinity College, Dublin. See also a Discourse addressed to Magistrates, &c. printed in 1736. In both of these publications, the author carries his Tory principles so far, as to represent the doctrine of passive obedience and non-resistance as an essential article of the Christian faith. "The Christian religion makes every legal constitution sacred, by commanding our submission thereto. Let every soul be subject to the higher powers saith St Paul, for the powers that be are ordained of God."

The solid additions, however, made by Berkeley to the stock of human knowledge were important and brilliant. Among these, the first place is unquestionably due to his *New Theory of Vision*; a work abounding with ideas so different from those commonly received, and, at the same time, so profound and refined, that it was regarded by all but a few accustomed to deep metaphysical reflection, rather in the light of a philosophical romance, than of a sober inquiry after truth. Such, however, has been since the progress and diffusion of this sort of knowledge, that the leading and most abstracted doctrines contained in it, form now an essential part of every elementary treatise of optics, and are adopted by the most superficial smatterers in science as fundamental articles of their faith.

Of a theory, the outlines of which cannot fail to be familiar to a great majority of my readers, it would be wholly superfluous to attempt any explanation here, even if it were consistent with the limits within which I am circumscribed. Suffice it to observe, that its chief aim is to distinguish the immediate and natural objects of sight from the *seemingly instantaneous* conclusions which experience and habit teach us to draw from them in our earliest infancy; or (in the more concise metaphysical language of a later period) to draw the line between the *original* and the *acquired perceptions* of the eye. They who wish to study it in detail, will find ample satisfaction, and, (if they have any relish for such studies) an inexhaustible fund of entertainment, in Berkeley's own short but masterly exposition of his principles, and in the excellent comments upon it by Smith of Cambridge; by Porterfield; by Reid; and, still more lately, by the author of the *Wealth of Nations*.¹

That this doctrine, with respect to the *acquired perceptions* of sight, was quite unknown to the best metaphysicians of antiquity, we have direct evidence in a passage of Aristotle's *Nicomachian Ethics*, where he states the distinction between these endowments which are the immediate gift of nature, and those which are the fruit of custom and habit. In the former class, he ranks the perceptions of sense, mentioning particularly the senses of seeing and of hearing. The passage (which I have transcribed in a *Note*) is curious, and seems to me decisive on the subject.²

¹ By this excellent judge, Berkeley's *New Theory of Vision* is pronounced to be "one of the finest examples of Philosophical Analysis that is to be found in our own, or any other language. (*Essays on Philosophical Subjects*. Lond. 1795, p. 215.)

² Οὐ γὰρ ἢ τε πολλὰκις ἰδεῖν, ἢ πολλὰκις ἀκούειν, τὰς αἰσθήσεις λαμβάνειν, ἀλλ' ἀναπαύειν, ἔχοντες ἐχρησασθαι, καὶ χρῆσασθαι ἐχόμεν. (*Ethic. Nicomach. Lib. ii. cap. 1.*)

"For it is not from seeing often, or from hearing often, that we get these senses; but, on the contrary,

The misapprehensions of the ancients on this very obscure question will not appear surprising, when it is considered, that *forty* years after the publication of Berkeley's *Theory of Vision*, and *sixty* years after the date of Locke's *Essay*, the subject was so imperfectly understood in France, that Condillac (who is, to this day, very generally regarded by his countrymen as the father of genuine logic and metaphysics) combated at great length the conclusions of the English philosophers concerning the *acquired* perceptions of sight; affirming that "the eye judges *naturally* of figures, of magnitudes, of situations, and of distances." His argument in support of this opinion is to be found in the sixth section of his *Essay on the Origin of Human Knowledge*.

It is difficult to suppose, that a person of mature years, who had read and studied Locke and Berkeley with as much care and attention as Condillac appears to have bestowed on them, should have reverted to this ancient and vulgar prejudice; without suspecting that his metaphysical depth has been somewhat overrated by the world.¹ It is but justice, however, to Condillac to add, that, in a subsequent work, he had the candour to acknowledge and to retract his error;—a rare example of that disinterested love of truth, which is so becoming in a philosopher. I quote the passage (in a literal, though somewhat abridged version), not only to show, that, in the above statement, I have not misrepresented his opinion, but because I consider this remarkable circumstance in his literary history as a peculiarly amiable and honourable *trait* in his character.

"We cannot recall to our memory the ignorance in which we were born: It is a state

instead of getting them by using them, we use them because we have got them."

Had Aristotle been at all aware of the distinction so finely illustrated by Berkeley, instead of appealing to the perceptions of these two senses, as instances of endowments coeval with our birth, he would have quoted them as the most striking of all examples, of the effects of Custom in apparently identifying our acquired powers with our original faculties.

¹ Voltaire, at an earlier period, had seized completely the scope of Berkeley's theory; and had explained it with equal brevity and precision, in the following passage of his *Elements of the Newtonian Philosophy*:

"Il faut absolument conclure, que les distances, les grandeurs, les situations ne sont pas, à proprement parler, des choses visibles, c'est à dire, ne sont pas les objets propres et immédiats de la vue. L'objet propre et immédiat de la vue n'est autre chose que la lumière colorée: tout le reste, nous ne le sentons qu'à la longue et par expérience. Nous apprenons à voir, précisément comme nous apprenons à parler et à lire. La différence est, que l'art de voir est plus facile, et que la nature est également à tous notre maître.

"Les jugemens soudains, presque uniformes, que toutes nos âmes à un certain âge portent des distances des grandeurs, des situations, nous font penser, qu'il n'y a qu'à ouvrir les yeux pour voir la manière dont nous voyons. On se trompe, il y faut le secours des autres sens. Si les hommes n'avoient que le sens de la vue, ils n'auroient aucun moyen pour connoître l'étendue en longueur, largeur et profondeur, et un pur esprit ne la connoitroit peut être, à moins que Dieu ne la lui révélât."—*Phys. Newton*, Chap. 7.

which leaves no trace behind it. We only recollect our ignorance of those things, the knowledge of which we recollect to have acquired; and to remark what we acquire, some previous knowledge is necessary. That memory which now renders us so sensible of the step from one acquisition to another, cannot remount to the first steps of the progress; on the contrary, it supposes them already made; and hence the origin of our disposition to believe them connate with ourselves. To say that we have learnt to see, to hear, to taste, to smell, to touch, appears a most extraordinary paradox. It seems to us that nature gave us the complete use of our senses the moment she formed them, and that we have always made use of them without study, because we are no longer obliged to study in order to use them. I retained these prejudices at the time I published my *Essay on the Origin of Human Knowledge*; the reasonings of Locke on a man born blind, to whom the sense of sight was afterwards given, did not undeceive me; and I maintained against this philosopher that the eye judges naturally of figures, of sizes, of situations, and of distances."—Nothing short of his own explicit avowal could have convinced me, that a writer of so high pretensions and of such unquestionable ingenuity as Condillac, had really commenced his metaphysical career under so gross and unaccountable a delusion.

In bestowing the praise of originality on Berkeley's *Theory of Vision*, I do not mean to say, that the whole merit of this Theory is exclusively his own. In this, as in most other cases, it may be presumed, that the progress of the human mind has been gradual: And, in point of fact, it will, on examination, be found, that Berkeley only took up the inquiry where Locke dropped it; following out his principles to their remoter consequences, and placing them in so great a variety of strong and happy lights, as to bring a doctrine till then understood but by a few, within the reach of every intelligent and attentive reader. For my own part, on comparing these two philosophers together, I am at a loss whether most to admire the powerful and penetrating sagacity of the one, or the fertility of invention displayed in the illustrations of the other. What can be more clear and forcible than the statement of Locke quoted in the Note below; and what an idea does it convey of his superiority to Condillac, when it is considered, that he anticipated *à priori* the same doctrine which was afterwards confirmed by the fine analysis of Berkeley, and demonstrated by the judicious experiments of Cheselden; while the French metaphysician, with all this accumulation of evidence before him, relapsed into a prejudice transmitted to modern times, from the very infancy of optical science!

1 "We are farther to consider (says Locke), concerning perception, that the ideas we receive by sense-

I believe it would be difficult to produce from any writer prior to Locke, an equal number of important facts relating to the intellectual phenomena, as well observed, and as unexceptionably described, as those which I have here brought under my reader's eye. It must appear evident, besides, to all who have studied the subject, that Locke has, in this passage, enunciated, in terms the most precise and decided, the same general conclusion

tion are often in grown people altered by the judgment, without our taking notice of it. When we set before our eyes a round globe, of any uniform colour, *v. g.* gold, alabaster, or jet, it is certain that the idea thereby imprinted in our mind is of a flat circle, variously shadowed, with several degrees of light and brightness coming to our eyes. But we having by use been accustomed to perceive what kind of appearance convex bodies are wont to make in us, what alterations are made in the reflections of light by the difference of the sensible figure of bodies; the judgment presently, by an habitual custom, alters the appearances into their causes, so that, from what truly is variety of shadow or colour, collecting the figure it makes it pass for a mark of figure, and frames to itself the perception of a convex figure, and an uniform colour; when the idea we receive from thence is only a plane variously coloured, as is evident in painting. * * * *

"But this is not, I think, usual in any of our ideas, but those received by sight; * because sight, the most comprehensive of all our senses, conveying to our minds the ideas of lights and colours, which are peculiar only to that sense; and also the far different ideas of space, figure, or motion, the several varieties whereof change the appearances of its proper objects, *viz.* light and colours, we bring ourselves by use to judge of the one by the other. This, in many cases, by a settled habit in things whereof we have frequent experience, is performed so constantly and so quick, that we take *that* for the perception of our sensation, which is an idea formed by our judgment; so that one, *viz.* that of sensation, serves only to excite the other, and is scarce taken notice of itself; as a man who reads or hears with attention or understanding, takes little notice of the characters or sounds, but of the ideas that are excited in him by them.

"Nor need we wonder that is done with so little notice, if we consider how very *quick* the actions of the mind are performed, for as itself is thought to take up no space, to have no extension; so its actions seem to require no time, but many of them seem to be crowded into an instant. I speak this in comparison to the actions of the body. Any one may easily observe this in his own thoughts, who will take the pains to reflect on them. How, as it were in an instant, do our minds with one glance see all the parts of a demonstration, which may very well be called a long one, if we consider the time it will require to put it into words, and step by step show it to another? Secondly, we shall not be so much surprised, that this is done in us with so little notice, if we consider how the facility which we get of doing things by a custom of doing makes them often pass in us without our notice. *Habits*, especially such as are begun very early, come at last to produce actions in us, which often escape our observations. How frequently do we in a day cover our eyes with our eye-lids, without perceiving that we are at all in the dark? Men that have by custom got the use of a bye-word, do almost in every sentence pronounce sounds, which, though taken notice of by others, they themselves neither hear nor observe; and, therefore, it is not so strange, that our mind should often change the idea of its *sensation* into that of its *judgment*, and make one serve only to excite the other, without taking notice of it." (Locke's *Works*, Vol. I. p. 123, *et seq.*)

* Mr Locke might, however, have remarked something very *similar* to it in the perceptions of the ear; a very large proportion of its appropriate objects being rather *judged of* than *actually perceived*. In the rapidity (for example) of common conversation, how many syllables, and even words, escape the notice of the most attentive hearer; which syllables and words are so quickly supplied from the relation which they bear to the rest of the sentence, that it is quite impossible to distinguish between the audible and the inaudible sounds! A very palpable instance of this occurs in the difficulty experienced by the most acute ear in catching *proper names* or arithmetical sums, or words borrowed from unknown tongues, the first time they are pronounced.

concerning the effect of constant and early *habits*, which it was the great object of Berkeley's *Theory of Vision* to establish, and which, indeed, gives to that work its chief value, when considered in connection with the Philosophy of the Human Mind.

Berkeley himself, it is to be observed, by no means lay claims to that complete novelty in his *Theory of Vision*, which has been ascribed to it by many who, in all probability, derived their whole information concerning it from the traditional and inexact transcripts of book-making historians. In the introductory sentences of his Essay, he states very clearly and candidly the conclusions of his immediate predecessors on this class of our perceptions; and explains, with the greatest precision, in what particulars his own opinion differs from theirs. "It is, I think, *agreed by all*, that distance, of itself, cannot be seen. For distance being a line directed end-wise to the eye, it projects only one point in the fund of the eye, which point remains invariably the same, whether the distance be longer or shorter.

"I find it also acknowledged, that the estimate we make of the distance of objects *considerably remote*, is rather an act of judgment grounded on *experience*, than of sense. For example, when I perceive a great number of intermediate objects, such as houses, fields, rivers, and the like, which I have experienced to take up a considerable space, I thence form a judgment or conclusion, that the object I see beyond them is at a great distance. Again, when an object appears faint and small, which, at a near distance, I have experienced to make a vigorous and large appearance, I instantly conclude it to be far off. And this, 'tis evident, is the result of *experience*; without which, from the faintness and littleness, I should not have inferred anything concerning the distance of objects.

"But when an object is placed at *so near a distance*, as that the interval between the eyes bears any sensible proportion to it, it is the received opinion that the two optic axes, concurring at the object, do there make an angle, by means of which, according as it is greater or less, the object is perceived to be nearer or farther off.

"There is another way mentioned by the optic writers, whereby they will have us judge of those distances, in respect of which the breadth of the pupil hath any sensible bigness; and that is, the greater or less divergency of the rays, which, issuing from the visible point, do fall on the pupil; that point being judged nearest, which is seen by most diverging rays, and that remotest, which is seen by less diverging rays."

These, (according to Berkeley) are the "common and current accounts" given by *mathematicians* of our perceiving *near distances* by sight. He then proceeds to show, that they are unsatisfactory; and that it is necessary, for the solution of this problem, to avail

ourselves of principles borrowed from a higher philosophy: After which, he explains, in detail, his own theory concerning the *ideas* (*sensations*) which, by experience, become *signs* of distance;¹ or (to use his own phraseology) “by which distance is *suggested*² to the mind.” The result of the whole is, that, “a man born blind, being made to see, would not at first have any idea of distance by sight. *The sun and stars, the remotest objects as well as the nearest, would all seem to be in his Eye, or rather in his Mind.*”³

From this quotation it appears, that, before Berkeley's time, philosophers had advanced greatly beyond the point at which Aristotle stopped, and towards which Condillac, in his first publication, made a retrograde movement. Of this progress some of the chief steps may be traced as early as the twelfth century in the Optics of Alhazen; ⁴ and they may be

¹ For assisting persons unaccustomed to metaphysical studies to enter into the spirit and scope of Berkeley's *Theory*, the best illustration I know of is furnished by the phenomena of the *Phantasmagoria*. It is sufficient to hint at this application of these phenomena, to those who know anything of the subject.

² The word *suggest* is much used by Berkeley in this appropriate and technical sense, not only in his *Theory of Vision*, but in his *Principles of Human Knowledge*, and in his *Minute Philosopher*. It expresses, indeed, the cardinal principle on which his *Theory of Vision* hinges; and is now so incorporated with some of our best metaphysical speculations, that one cannot easily conceive how the use of it was so long dispensed with. Locke (in the passage quoted in the Note, p. 107) uses the word *excite* for the same purpose: but it seems to imply an hypothesis concerning the *mechanism* of the mind, and by no means expresses the fact in question with the same force and precision.

It is remarkable, that Dr Reid should have thought it incumbent on him to apologize for introducing into philosophy a word so familiar to every person conversant with Berkeley's works. “I beg leave to make use of the word *suggestion*, because I know not one more proper to express a power of the mind, which seems entirely to have escaped the notice of philosophers, and to which we owe many of our simple notions which are neither impressions nor ideas, as well as many original principles of belief. I shall endeavour to explain, by an example, what I understand by this word. We all know that a certain kind of sound *suggests* immediately to the mind a coach passing in the street; and not only produces the imagination, but the belief, that a coach is passing. Yet there is no comparing of ideas, no perception of agreements or disagreements to produce this belief; nor is there the least similitude between the sound we hear, and the coach we imagine and believe to be passing.”

So far Dr Reid's use of the word coincides exactly with that of Berkeley; but the former will be found to annex to it a meaning more extensive than the latter, by employing it to comprehend not only those *intimations* which are the result of experience and habit; but another class of *intimations* (quite overlooked by Berkeley), those which result from the original frame of the human mind. (See Reid's *Inquiry*, Chap. ii. sec. 7.)

³ I request the attention of my readers to this last sentence, as I have little doubt that the fact here stated gave rise to the theory which Berkeley afterwards adopted, concerning the non-existence of the material world. It is not, indeed, surprising that a conclusion, so very curious with respect to the objects of sight, should have been, in the first ardour of discovery, too hastily extended to those qualities also which are the appropriate objects of touch.

⁴ Alhazen, Lib. ii. NN. 10, 12, 39.

perceived still more clearly and distinctly in various optical writers since the revival of letters; particularly in the *Optica Promota* of James Gregory.¹ Father Malebranche went still farther, and even anticipated some of the *metaphysical* reasonings of Berkeley concerning the means by which experience enables us to judge of the distances of *near* objects. In proof of this, it is sufficient to mention the explanation he gives of the manner in which a comparison of the perceptions of sight and of touch teaches us gradually to estimate by the eye the distances of all those objects which are within reach of our hands, or of which we are accustomed to measure the distance, by walking over the intermediate ground.

In rendering this justice to earlier writers, I have no wish to detract from the originality of Berkeley. With the single exception, indeed, of the passage in Malebranche which I have just referred to, and which it is more than probable was unknown to Berkeley when his theory first occurred to him,² I have ascribed to his predecessors nothing more than what he has himself explicitly acknowledged to belong to them. All that I wished to do was, to supply some links in the historical chain, which he has omitted.

The influence which this justly celebrated work has had, not only in perfecting the theory of optics, but in illustrating the astonishing effects of early habit on the mental phenomena in general, will sufficiently account to my intelligent readers for the length to which the foregoing observations upon it have extended.

Next in point of importance to Berkeley's New Theory of Vision, which I regard as by far the most solid basis of his philosophical fame, may be ranked his speculations concerning the Objects of General Terms and his celebrated argument against the existence of the Material World. On both of these questions I have elsewhere explained my own ideas so fully, that it would be quite superfluous for me to resume the consideration of them here.³ In neither instance are his reasonings so entirely original as has been commonly supposed. In the former, they coincide in substance, although with immense improvements in the form, with those of the scholastic nominalists, as revived and modified by Hobbes and Leibnitz. In the latter instance, they amount to little more than an ingenious and elegant developement of some principles of Malebranche, pushed to certain paradoxical but obvious consequences, of which Malebranche, though unwilling to avow them, appears to have been fully aware. These consequences, too, had been previously pointed out by

¹ See the end of Prop. 28.

² Berkeley's *Theory* was published when he was only twenty-five; an age when it can scarcely be supposed that his metaphysical reading had been very extensive.

³ See *Philosophical Essays*.

Mr Norris, a very learned divine of the Church of England, whose name has unaccountably failed in obtaining that distinction to which his acuteness as a logician, and his boldness as a theorist, justly entitled him.¹

The great object of Berkeley in maintaining his system of idealism, it may be proper to remark in passing, was to cut up by the roots the scheme of materialism. "Matter (he tells us himself) being once *expelled out of nature*, drags with it so many sceptical and impious notions. * * * Without it, your Epicureans, Hobbists, and 'the like, have not even the shadow of a pretence, but become the most cheap and easy triumph in the world."

Not satisfied with addressing these abstract speculations to the learned, Berkeley conceived them to be of such moment to human happiness, that he resolved to bring them, if possible, within the reach of a wider circle of readers, by throwing them into the more popular and amusing form of dialogues.² The skill with which he has executed this very difficult and unpromising task cannot be too much admired. The characters of his speakers are strongly marked and happily contrasted; the illustrations exhibit a singular combination of logical subtilty and of poetical invention; and the style, while it everywhere abounds with the rich, yet sober colourings of the author's fancy, is perhaps superior, in point of purity and of grammatical correctness, to any English composition of an earlier date.³

¹ Another very acute metaphysician of the same church (Arthur Collier, author of a *Demonstration of the Non-existence and Impossibility of an External World*) has met with still greater injustice. His name is not to be found in any of our Biographical Dictionaries. In point of date, his publication is some years posterior to that of Norris, and therefore it does not possess the same claims to originality; but it is far superior to it in logical closeness and precision, and is not obscured to the same degree with the mystical theology which Norris (after the example of Malebranche) connected with the scheme of Idealism. Indeed, when compared with the writings of Berkeley himself, it yields to them less in force of argument, than in composition and variety of illustration. The title of Collier's book is *Clavis Universalis, or a New Inquiry after Truth, being a Demonstration, &c. &c.* By Arthur Collier, Rector of Langford Magna, near Sarum. (Lond. printed for Robert Gosling, at the Mitre and Crown, against St Dunstan's Church, Fleet Street, 1713.) The motto prefixed by Collier to his work is from Malebranche, and is strongly characteristical both of the English and French *Inquirer after Truth*. "Vulgi assensus et approbatio circa materiam difficilem est certum argumentum falsitatis istius opinionis cui assentitur." (*Maleb. De Inquir. Verit. Lib. iii. p. 194.*) See Note (AA.)

² I allude here chiefly to *Alciphron, or the Minute Philosopher*; for as to the dialogues between *Hylas* and *Philonous*, they aspire to no higher merit than that of the common dialogues between A. and B.; being merely a compendious way of stating and of obviating the principal objections which the author anticipated to his opinions.

³ Dr Warton, after bestowing high praise on the *Minute Philosopher*, excepts from his encomium "those passages in the fourth dialogue, where the author has introduced his fanciful and whimsical opinions about

The impression produced in England by Berkeley's Idealism was not so great as might have been expected; but the novelty of his paradoxes attracted very powerfully the attention of a set of young men who were then prosecuting their studies at Edinburgh, and who formed themselves into a Society for the express purpose of soliciting from the author an explanation of some parts of his theory which seemed to them obscurely or equivocally expressed. To this correspondence the amiable and excellent prelate appears to have given every encouragement; and I have been told by the best authority, that he was accustomed to say, that his reasonings had been nowhere better understood than by this club of young Scotsmen.¹ The ingenious Dr Wallace, author of the *Discourse on the Numbers of Mankind*, was one of the leading members; and with him were associated several other individuals, whose names are now well known and honourably distinguished in the learned world. Mr Hume's *Treatise of Human Nature*, which was published in 1739, affords sufficient evidence of the deep impression which Berkeley's writings had left upon his mind; and to this juvenile essay of Mr Hume's may be traced the origin of the most important metaphysical works which Scotland has since produced.

It is not, however, my intention to prosecute farther, at present, the history of Scottish philosophy. The subject may be more conveniently, and I hope advantageously resumed, after a slight review of the speculations of some English and French writers, who, while they professed a general acquiescence in the doctrines of Locke, have attempted to modify his fundamental principles in a manner totally inconsistent with the views of their master. The remarks which I mean to offer on the modern French school will afford me, at the same time, a convenient opportunity of introducing some strictures on the metaphysical systems which have of late prevailed in other parts of the Continent.

vision."—(*Essay on the Writings and Genius of Pope*, Vol. II. p. 264.)—If I were called on to point out the most ingenious and original part of the whole work, it would be the argument contained in the passages here so contemptuously alluded to, by this learned and (on all questions of taste) most respectable critic.

¹ The authority I here allude to is that of my old friend and preceptor, Dr John Stevenson, who was himself a member of the Rankenian Club, and who was accustomed for many years to mention this fact in his *Academatic Prelections*.

SECTION V.

Hartleian School.

THE English writers to whom I have alluded in the last paragraph, I shall distinguish by the title of Dr Hartley's School; for although I by no means consider this person as the first author of any of the theories commonly ascribed to him (the seeds of all of them having been previously sown in the university where he was educated), it was nevertheless reserved for him to combine them together, and to exhibit them to the world in the imposing form of a system.

Among the immediate predecessors of Hartley, Dr Law, afterwards Bishop of Carlisle, seems to have been chiefly instrumental in preparing the way for a schism among Locke's disciples. The name of Law was first known to the public by an excellent translation, accompanied by many learned, and some very judicious notes, of Archbishop King's work on the Origin of Evil; a work of which the great object was to combat the Optimism of Leibnitz, and the Manicheism imputed to Bayle. In making this work more generally known, the translator certainly rendered a most acceptable and important service to the world, and, indeed, it is upon this ground that his best claim to literary distinction is still founded.¹ In his own original speculations, he is weak, paradoxical, and oracular;² af-

¹ King's argument in proof of the prevalence in this world, both of Natural and Moral Good, over the corresponding Evils, has been much and deservedly admired; nor are Law's Notes, upon this head entitled to less praise. Indeed, it is in this part of the work that both the author and his commentator appear, in my opinion, to the greatest advantage.

² As instances of this I need only refer to the *first* and *third* of his Notes on King: the former of which relates to the word *substance*; and the latter to the dispute between Clarke and Leibnitz concerning *space*. His reasonings on both subjects are obscured by an affected use of hard and unmeaning words, ill becoming so devoted an admirer of Locke. The same remark may be extended to an *Inquiry into the Ideas of Space and Time*, published by Dr Law in 1734.

The result of Law's speculations on Space and Time is thus stated by himself: "That our ideas of them do not imply any external *ideatum* or *objective* reality; that these ideas (as well as those of *infinity* and *number*) are *universal* or *abstract* ideas, existing under that *formality* no where but in the mind; nor affording a proof of any thing, but of the power which the mind has to form them." (Law's *Trans. of King*, p. 7. 4th edit.) This language, as we shall afterwards see, approaches very nearly to that lately introduced by Kant. Dr Law's favourite author might have cautioned him against such jargon. (See *Essay on the Human Understanding*, Book II. Chap. xiii. § 17, 18.)

The absurd application of the scholastic word *substance* to empty space; an absurdity in which the powerful

fecting, on all occasions, the most profound veneration for the opinions of Locke, but much more apt to attach himself to the errors and oversights of that great man, than to enter into the general spirit of his metaphysical philosophy.

To this translation, Dr. Law prefixed a Dissertation concerning the Fundamental Principle of Virtue, by the Reverend Mr Gay; a performance of considerable ingenuity, but which would now be entitled to little notice, were it not for the influence it appears to have had in suggesting to Dr Hartley the possibility of accounting for all our intellectual pleasures and pains, by the single principle of the Association of Ideas. We are informed by Dr Hartley himself, that it was in consequence of hearing some account of the contents of this dissertation, he was first led to engage in those inquiries which produced his celebrated *Theory of Human Nature*.

The other principle on which this theory proceeds (that of the vibrations and vibrations in the medullary substance of the brain) is also of Cambridge origin. It occurs in the form of a query in Sir Isaac Newton's *Optics*; and a distinct allusion to it, as a principle likely to throw new light on the phenomena of mind, is to be found in the concluding sentence of Smith's *Harmonics*.

Very nearly about the time when Hartley's *Theory* appeared, Charles Bonnet of Geneva published some speculations of his own, proceeding almost exactly on the same assumptions. Both writers speak of vibrations (*ébranlemens*) in the nerves; and both of them have recourse to a subtile and elastic ether, co-operating with the nerves in carrying on the communication between soul and body.¹ This fluid Bonnet conceived to be contained in the nerves, in a manner analogous to that in which the electric fluid is contained in the solid bodies which conduct it; differing in this respect from the Cartesians as well as from the ancient physiologists, who considered the nerves as hollow tubes, or pipes, within which the animal spirits were included. It is to this elastic ether that Bonnet ascribes the vibrations of which he supposes the nerves to be susceptible; for the nerves themselves (he justly observes) have no resemblance to the stretched cords of a musical instrument.²

mind of Gravesande acquiesced many years after the publication of the *Essay on Human Understanding*, has probably contributed not a little to force some authors into the opposite extreme of maintaining, with Leibnitz and Dr Law, that our idea of space does not imply any external *ideatum* or objective reality. Gravesande's words are these: "Substantiæ sunt aut cogitantes, aut non cogitantes; cogitantes duas novimus, Deum et Mentem nostram: præter has et alias de quibus in dubium non revocamus. Dux etiam substantiæ, quæ non cogitant, nobis notæ sunt Spatium et Corpus."—Gravesande, *Introd. ad Philosophiam*, § 19.

¹ *Essai Analytique de l'Ame*, Chap. v. See also the additional notes on the first chapter of the seventh part of the *Contemplation de la Nature*.

² "Mais les nerfs sont mols, ils ne sont point tendus comme les cordes d'un instrument; les objets y

Hartley's *Theory* differs in one respect from this, as he speaks of vibrations and vibrations in the medullary substance of the brain and nerves. He agrees, however, with Bonnet in thinking, that to these vibrations in the nerves the co-operation of the ether is essentially necessary; and, therefore, at bottom the two hypothesis may be regarded as in substance the same. As to the trifling shade of difference between them, the advantage seems to me to be in favour of Bonnet.

Nor was it only in their Physiological Theories concerning the nature of the union between soul and body, that these two philosophers agreed. On all the great articles of metaphysical theology, the coincidence between their conclusions is truly astonishing. Both held the doctrine of Necessity in its fullest extent; and both combined with it a vein of mystical devotion, setting at defiance the creeds of all established churches. The intentions of both are allowed, by those who best knew them, to have been eminently pure and worthy; but it cannot be said of either, that his metaphysical writings have contributed much to the instruction or to the improvement of the public. On the contrary, they have been instrumental in spreading a set of speculative tenets very nearly allied to that sentimental and fanatical modification of Spinozism, which, for many years past, has prevailed so much, and produced such mischievous effects in some parts of Germany.

exciteroient-ils donc les vibrations analogues à celle d'une corde pincée? Ces vibrations se communiqueroient-elles à l'instant au siège de l'ame? La chose paroît difficile à concevoir. Mais si l'on admet dans les nerfs un fluide dont la subtilité et l'élasticité approche de celle de la lumière ou de l'éther, on expliquera facilement par le secours de ce fluide, et la célérité avec laquelle les impressions se communiquent à l'ame, et celle avec laquelle l'ame exécute tant d'opérations différentes." (*Essai Anal.* Chap. v.)

"Au reste, les physiologistes qui avoient cru que les filets nerveux étoient solides, avoient cédé à des apparences trompeuses. Ils vouloient d'ailleurs faire osciller les nerfs pour rendre raison des sensations, et les nerfs ne peuvent osciller. Ils sont mous, et nullement élastiques. Un nerf coupé ne se retire point. C'est le fluide invisible que les nerfs renferment, qui est doué de cette élasticité qu'on leur attribuoit, et d'une plus grande élasticité encore." (*Contemp. de la Nature*, VII. Partie, Chap. i. Note at the end of the chapter.)

M. Quesnai, the celebrated author of the *Economical System*, has expressed himself to the same purpose concerning the supposed vibrations of the nerves: "Plusieurs physiciens ont pensé que le seul ébranlement des nerfs, causé par les objets qui touchent les organes des corps, suffit pour occasioner le mouvement et le sentiment dans les parties où les nerfs sont ébranlés. Ils se représentent les nerfs comme des cordes fort tendues, qu'un léger contact met en vibration dans toute leur étendue. Des philosophes, peu instruits en anatomie, ont pu se former une telle idée. . . . Mais cette tension qu'on suppose dans les nerfs, et qui les rend si susceptibles, d'ébranlement et de vibration, est si grossièrement imaginée qu'il seroit ridicule de s'occuper sérieusement à la refuter." (*Econ. Animale*, sect. 3. c. 13.)

As this passage from Quesnai is quoted by Condillac, and sanctioned by his authority (*Traité des Animaux*, Chap. iii.), it would appear that the hypothesis which supposes the nerves to perform their functions by means of vibrations was going fast into discredit, both among the metaphysicians and the physiologists of France, at the very time when it was beginning to attract notice in England, in consequence of the visionary speculations of Hartley.

But it is chiefly by his application of the associating principle to account for all the mental phenomena that Hartley is known to the world; and upon this I have nothing to add to what I have already stated in another work. (*Phil. Essays*, Essay IV.) His Theory seems to be already fast passing into oblivion; the temporary popularity which it enjoyed in this country having, in a great measure, ceased with the life of its zealous and indefatigable apostle Dr Priestley.¹

It would be unfair, however, to the translator of Archbishop King, to identify his opinions with those of Hartley and Priestley. The zeal with which he contends for man's free agency is sufficient, of itself, to draw a strong line of distinction between his Ethical System and their's. (See his Notes on King, *passim*.) But I must be allowed to say of him, that the general scope of his writings tends, in common with that of the two other metaphysicians, to depreciate the evidences of Natural Religion, and more especially to depreciate the evidences which the light of nature affords of a life to come; "a doctrine equally necessary to comfort the weakness, and to support our lofty ideas of the grandeur of human nature;"² and of which it seems hard to confine exclusively the knowledge to that portion of mankind who have been favoured with the light of Revelation. The influence of the same fundamental error, arising, too, from the same mistaken idea, of thus strengthening the cause of Christianity, may be traced in various passages of the posthumous work of the late Bishop of Llandaff. It is wonderful that the reasonings of Clarke and of Butler did not teach these eminent men a sounder and more consistent logic; or, at least, open their eyes to the inevitable consequences of the rash concessions which they made to their adversaries.³

Among the disciples of Law, one illustrious exception to these remarks occurs in Dr

¹ Dr Priestley's opinion of the merits of Hartley's work is thus stated by himself: "Something was done in this field of knowledge by Descartes, very much by Mr Locke, but most of all by Dr Hartley, who has thrown more useful light upon the theory of the mind, than Newton did upon the theory of the natural world." (*Remarks on Reid, Beattie, and Oswald*, p. 2. London, 1774.)

² Smith's *Theory of Moral Sentiments*, 6th Ed. Vol. I. pp. 325, 326.

Dr Law's doctrine of the sleep of the soul, to which his high station in the church could not fail to add much weight in the judgment of many, is, I believe, now universally adopted by the followers of Hartley and Priestley; the theory of vibrations being evidently inconsistent with the supposition of the soul's being able to exercise her powers in a separate state from the body.

³ Without entering at all into the argument with Dr Law or his followers, it is sufficient here to mention, as an historical fact, their wide departure from the older lights of the English church, from Hooker downwards. "All religion (says Archbishop Tillotson, whom I select as an unexceptionable organ of their common sentiments) is founded on right notions of God and his perfections, insomuch that Divine Revelation

Paley, whose treatise on Natural Theology is unquestionably the most instructive as well as interesting publication on that subject which has appeared in our times. As the book was intended for popular use, the author has wisely avoided, as much as possible, all metaphysical discussions; but I do not know that there exists any other work where the argument from *final causes* is placed in so great a variety of pleasing and striking points of view.

SECTION VI.

Condillac, and other French Metaphysicians of a later date.

WHILE Hartley and Bonnet were indulging their imagination in theorizing concerning the nature of the union between soul and body, Condillac was attempting to draw the attention of his countrymen to the method of studying the phenomena of Mind recommended and exemplified by Locke.¹ Of the vanity of expecting to illustrate, by physiolo-

itself does suppose these for its foundations; and can signify nothing to us unless they be first known and believed; so that the principles of natural religion are the foundation of that which is revealed." (Sermon 41.) "There is an intrinsical good and evil in things, and the reasons and respects of moral good and evil are fixed and immutable, eternal and indispensable. Nor do they speak safely who make the Divine will the rule of moral good and evil, as if there were nothing good or evil in its own nature antecedently to the will of God; but, that all things are therefore good and evil because God wills them to be so." (Sermon 88.) "Natural religion is obedience to the natural law, and the performance of such duties as natural light, without any express and supernatural revelation, doth dictate to men. These lie at the bottom of all religion, and are the great fundamental duties which God requires of all mankind. These are the surest and most sacred of all other laws; those which God hath rivetted in our souls and written upon our hearts; and these are what we call moral duties, and most valued by God, which are of eternal and perpetual obligation, because they do naturally oblige, without any particular and express revelation from God; and these are the foundation of revealed and instituted religion; and all revealed religion does suppose them and build upon them." Sermons 48, 49.

¹ It may appear to some unaccountable, that no notice should have been taken, in this Dissertation, of any French metaphysician during the long interval between Malebranche and Condillac. As an apology for this apparent omission, I beg leave to quote the words of an author intimately acquainted with the history of French literature and philosophy, and eminently qualified to appreciate the merits of those who have contributed to their progress. "If we except (says Mr. Adam Smith, in a *Memoir* published in 1755) the *Meditations* of Descartes, I know of nothing in the works of French writers which aspires at originality in morals or metaphysics; for the philosophy of Regius and that of Malebranche are nothing more than the meditations of Descartes, unfolded with more art and refinement. But Hobbes, Locke, Dr Mandeville, Lord Shaftesbury, Dr Butler, Dr Clarke, and Mr Hutcheson, each in his own system, all different and all incompatible, have tried to be original, at least in some points. They have attempted to add something to the fund of observations collected by their

gical conjectures, the manner in which the intercourse between the thinking principle and the external world is carried on, no philosopher seems ever to have been more completely aware; and, accordingly, he confines himself strictly, in all his researches concerning this intercourse, to an examination of the general laws by which it is regulated. There is, at the same time, a remarkable coincidence between some of his views and those of the other two writers. All of the three, while they profess the highest veneration for Locke, have abandoned his account of the origin of our ideas for that of Gassendi; and, by doing so, have, with the best intentions, furnished arms against those principles which it was their common aim to establish in the world.¹ It is much to be regretted, that by far the greater part of those French writers who have since speculated about the human mind, have acquired the whole of their knowledge of Locke's philosophy through this mistaken comment upon its fundamental principle. On this subject I have already exhausted all that I have to offer on the effect of Condillac's writings; and I flatter myself have sufficiently shown how widely his commentary differs from the text of his author. It is this commentary, however, which is now almost universally received on the Continent as the doctrine of Locke, and which may justly be regarded as the sheet-anchor of those systems which are commonly stigmatised in England with the appellation of French philosophy. Had Condillac been sufficiently aware of the consequences which have been deduced (and I must add *logically* deduced) from his account of the origin of our knowledge, I am per-

predecessors, and already the common property of mankind. This branch of science, which the English themselves neglect at present, appears to have been recently transported into France. I discovered some traces of it not only in the *Encyclopédie*, but in the *Theory of Agreeable Sensations*, by M. de Pouilly, and much more in the late discourse of M. Rousseau, *On the Origin and Foundation of the Inequality of Ranks among Men.*"

Although I perfectly agree with Mr Smith in his general remark on the sterility of invention among the French metaphysicians posterior to Descartes, when compared to those of England, I cannot pass over the foregoing quotation without expressing my surprise, 1st, To find the name of Malebranche (one of the highest in modern philosophy) degraded to a level with that of Regius; and, 2dly, To observe Mr Smith's silence with respect to Buffier and Condillac, while he mentions the author of the *Theory of Agreeable Sensations* as a metaphysician of original genius. Of the merits of Condillac, whose most important works were published several years before this paper of Mr Smith's, I am about to speak in the text; and those of Buffier I shall have occasion to mention in a subsequent part of this discourse. In the mean time, I shall only say of him, that I regard him as one of the most original as well as sound philosophers of whom the eighteenth century has to boast.

¹ Condillac's earliest work appeared three years before the publication of Hartley's *Theory*. It is entitled, "*Essai sur l'Origine des Connoissances Humaines. Ouvrage on l'on réduit d'un seul principe tout ce qui concerne l'entendement humain.*" This *seul principe* is the association of ideas. The account which both authors give of the transformation of sensations into ideas is substantially the same.

suaded, from his known candour and love of truth, that he would have been eager to acknowledge and to retract his error.

In this apparent simplification and generalization of Locke's doctrine, there is, it must be acknowledged, something, at first sight, extremely seducing. It relieves the mind from the painful exercise of abstracted reflection, and amuses it with analogy and metaphor when it looked only for the severity of logical discussion. The clearness and simplicity of Condillac's style add to the force of this illusion, and flatter the reader with an agreeable idea of the powers of his own understanding, when he finds himself so easily conducted through the darkest labyrinths of metaphysical sciences. It is to this cause I would chiefly ascribe the great popularity of his works. They may be read with as little exertion of thought as a history or a novel; and it is only when we shut the book, and attempt to express in our own words, the substance of what we have gained, that we have the mortification to see our supposed acquisitions vanish into air.

The philosophy of Condillac was, in a more peculiar manner, suited to the taste of his own country, where (according to Mad. de Stael) "few read a book but with a view to talk of it."¹ Among such a people, speculations which are addressed to the power of reflection can never expect to acquire the same popularity with theories expressed in a metaphorical language, and constantly recalling to the fancy the impressions of the external senses. The state of society in France, accordingly, is singularly unfavourable to the inductive philosophy of the human mind; and of this truth no proof more decisive can be produced, than the admiration with which the metaphysical writings of Condillac have been so long regarded.

On the other hand, it cannot be denied that Condillac has, in many instances, been eminently successful, both in observing and describing the mental phenomena; but, in such cases, he commonly follows Locke as his guide; and, wherever he trusts to his own judgment, he seldom fails to wander from his way. The best part of his works relates to the action and reaction of thought and language on each other, a subject which had been previously very profoundly treated by Locke, but which Condillac has had the merit of placing in many new and happy points of view. In various cases, his conclusions are pushed too far; and in others are expressed without due precision; but, on the whole, they form a most valuable accession to this important branch of logic; and (what not a

¹ "En France, on ne lit guère un ouvrage que pour en parler." (*Allemagne*, Tom. I. p. 292.) The same remark, I am much afraid, is becoming daily more and more applicable to our own island.

little enhances their value) they have been instrumental in recommending the subject to the attention of other inquirers, still better qualified than their author to do it justice.

In the speculation, too, concerning the origin and the theoretical history of language, Condillac was one of the first who made any considerable advances; nor does it reflect any discredit on his ingenuity, that he has left some of the principal difficulties connected with the inquiry very imperfectly explained. The same subject was soon after taken up by Mr Smith, who, I think, it must be owned, has rather slurred over these difficulties, than attempted to remove them; an omission on his part the more remarkable, as a very specious and puzzling objection had been recently stated by Rousseau, not only to the theory of Condillac, but to all speculations which have for their object the solution of the same problem. "If language" (says Rousseau) "be the result of human convention, and if words be essential to the exercise of thought, language would appear to be necessary for the invention of language."¹—"But" (continues the same author) "when, by means *which I cannot conceive*, our new grammarians began to extend their ideas, and to generalize their words, their ignorance must have confined them within very narrow bounds. How, for example, could they imagine or comprehend such words as matter, mind, substance, mode, figure, motion, since our philosophers, who have so long made use of them, scarcely understand them, and since the ideas attached to them, being purely metaphysical, can have no model in nature?"

"I stop at these first steps" (continues Rousseau), "and entreat my judges to pause, and consider the distance between the easiest part of language, the invention of physical substantives, and the power of expressing all the thoughts of man, so as to speak in public, and influence society. I entreat them to reflect upon the time and knowledge it must have required to discover numbers, abstract words, aorists, and all the tenses of verbs, particles, syntax, the art of connecting propositions and arguments, and how to form the whole logic of discourse. As for myself, alarmed at these multiplying difficulties, and convinced of the almost demonstrable impossibility of language having been formed and established by means merely human, I leave to others the discussion of the problem, "Whether a so-

¹ That men could never have invented an artificial language, if they had not possessed a natural language, is an observation of Dr Reid's; and it is this indisputable and self-evident truth which gives to Rousseau's remark that imposing plausibility, which, at first sight, dazzles and perplexes the judgment. I by no means say, that the former proposition affords a key to all the difficulties suggested by the latter; but it advances us at least one important step towards their solution.

ciety already formed was more necessary for the institution of language, or a language, already invented for the establishment of society?"¹

Of the various difficulties here enumerated, *that* mentioned by Rousseau, in the last sentence, was plainly considered by him as the greatest of all; or rather as comprehending under it all the rest. But this difficulty arises merely from his own peculiar and paradoxical theory about the artificial origin of society; a theory which needs no refutation, but the short and luminous aphorism of Montesquieu, that "man is born in society, and there he remains." The other difficulties touched upon by Rousseau, in the former part of this quotation, are much more serious, and have never yet been removed in a manner completely satisfactory: And hence some very ingenious writers have been led to conclude, that language could not possibly have been the work of human invention. This argument has been lately urged with much acuteness and plausibility by Dr Magee of Dublin, and by M. de Bonald of Paris.² It may, however, be reasonably questioned, if these philosophers would not have reasoned more logically, had they contented themselves with merely affirming, that the problem has not yet been solved, without going so far as to pronounce it to be absolutely insolvable. For my own part, when I consider its extreme difficulty, and the short space of time during which it has engaged the attention of the learned, I am more disposed to wonder at the steps which have been already gained in the research, than at the number of *desiderata* which remain to employ the ingenuity of our successors. It is justly remarked by Dr Ferguson, that, "when language has attained to that perfection to which it arrives in the progress of society, the speculative mind, in comparing the first and the last stages of the progress, feels the same sort of amazement with a traveller, who, after rising insensibly on the slope of a hill, comes to look down from a precipice, to the summit of which he scarcely believes he could have ascended without supernatural aid."³

¹ *Discours sur l'origine et les fondemens de l'inégalité parmi les hommes.*

² The same theory has been extended to the art of writing; but if *this* art was first taught to man by an express revelation from Heaven, what account can be given of its present state in the great empire of China? Is the mode of writing practised there of divine or of human origin?

³ *Principles of Political and Moral Science*, Vol. I. p. 43. Edin. 1792. To this observation may be added, by way of comment, the following reflections of one of the most learned prelates of the English church: "Man, we are told, had a language from the beginning; for he conversed with God, and gave to every animal its particular name. But how came man by language? He must either have had it from *inspiration*, ready formed from his Creator, or have *derived* it by the exertion of those faculties of the mind, which were implanted in him as a rational creature, from natural and external objects with which he was surrounded. Scripture is silent on the means by which it was acquired. We are not, therefore, warranted to affirm, that it was re-

With respect to some of the difficulties pointed out by Rousseau and his commentators, it may be here remarked in passing (and the observation is equally applicable to various passages in Mr Smith's dissertation on the same subject), that the difficulty of explaining the theory of any of our intellectual operations affords no proof of any difficulty in applying that operation to its proper practical purpose; nor is the difficulty of explaining the metaphysical nature of any part of speech a proof, that, in its first origin, it implied any extraordinary effort of intellectual capacity. How many metaphysical difficulties might be raised about the mathematical notion of a *line*? And yet this notion is perfectly comprehended by every peasant, when he speaks of the distance between two places; or of the length, breadth, or height of his cottage. In like manner, although it may be difficult to give a satisfactory account of the origin and import of such words, as *of* or *by*, we ought not to conclude, that the invention of them implied any metaphysical knowledge in the individual who first employed them.¹ Their import, we see, is fully understood by children of three or four years of age.

In this view of the History of Language I have been anticipated by Dr Ferguson. "Parts of speech" (says this profound and original writer), "which, in speculation, cost

ceived by *inspiration*, and there is no internal evidence in language to lead us to such a supposition. On this side, then, of the question, we have nothing but uncertainty; but on a subject, the causes of which are so remote, nothing is more convenient than to refer them to *inspiration*, and to recur to that easy and comprehensive argument,

Διὸς δὲ τιμωτο βούλην

that is, man enjoyed the great privilege of speech, which distinguished him at first, and still continues to distinguish him as a *rational* creature, so eminently from the brute creation, without exerting those *reasoning* faculties, by which he was in *other* respects enabled to raise himself so much above their level. Inspiration, then, seems to have been an argument adopted and made necessary by the difficulty of accounting for it otherwise; and the name of *inspiration* carries with it an awfulness, which forbids the unhallowed approach of inquisitive discussion." (*Essay on the Study of Antiquities*, by Dr. Burgess, 2d edit. Oxford, 1782. Pp. 85, 86.)

It is farther remarked very sagaciously, and I think very decisively, by the same author, that "the supposition of man having received a language ready formed from his Creator, is *actually* inconsistent with the evidence of the origin of our ideas, which exists in language. For, as the origin of our ideas is to be traced in the words through which the ideas are conveyed, so the origin of language is referable to the source from whence our (*first*) ideas are derived, namely, *natural* and *external* objects." (*Ibid.* pp. 83, 84.)

¹ In this remark I had an eye to the following passage in Mr. Smith's dissertation: "It is worth while to observe, that those prepositions, which, in modern languages, hold the place of the ancient cases, are, of all others, the most general and abstract, and metaphysical; and, of consequence, would probably be the last invented. Ask my man of common acuteness, what relation is expressed by the preposition *above*? He will readily answer, that of *superiority*. By the preposition *below*? He will as quickly reply, that of *inferiority*. But ask him what relation is expressed by the preposition *of*? and, if he has not beforehand employed his thoughts a good deal upon these subjects, you may safely allow him a week to consider of his answer."

the grammarian so much study, are, in practice, familiar to the vulgar. The rudest tribes, even the idiot and the insane, are possessed of them. They are soonest learned in childhood, insomuch that we must suppose human nature, in its lowest state, competent to the use of them; and, without the intervention of uncommon genius, mankind, in a succession of ages, qualified to accomplish in detail this amazing fabric of language, which, when raised to its height, appears so much above what could be ascribed to any simultaneous effort of the most sublime and comprehensive abilities."¹

¹ The following judicious reflections, with which M. Raynouard concludes the introduction to his *Elémens de la Langue Romane*, may serve to illustrate some of the above observations. The modification of an existing language is, I acknowledge, a thing much less wonderful than the formation of a language entirely new; but the processes of thought, it is reasonable to think, are, in both cases, of the same kind; and the consideration of the one is at least a step gained towards the elucidation of the other.

“ La langue Romane est peut-être la seule à la formation de laquelle il soit permis de remonter ainsi, pour découvrir et expliquer le secret de son industrieux mécanisme. . . . J’ose dire que l’esprit philosophique, consulté sur le choix des moyens qui devraient épargner à l’ignorance beaucoup d’études pénibles et fastidieuses, n’eût pas été aussi heureux que l’ignorance elle-même; il est vrai qu’elle avoit deux grands maîtres; la NÉCESSITÉ et le TEMS.

“ En considérant à quelle époque d’ignorance et de barbarie s’est formé et perfectionné ce nouvel idiôme d’après des principes indiqués seulement par l’analogie et l’euphonie, on se dira peut-être comme je me le suis dit; l’homme porte en soi-même les principes d’une logique naturelle, d’un instinct régulateur, que nous admirons quelquefois dans les enfans. Oui, la providence nous a doté de la faculté indestructible et des moyens ingénieux d’exprimer, de communiquer, d’éterniser par la parole, et par les signes permanens ou elle se reproduit, cette pensée qui est l’un de nos plus beaux attributs, et qui nous distingue si éminemment et si avantageusement dans l’ordre de la création.” (*Elémens de la Grammaire de la Langue Romane avant l’An. 1000.* Pp. 104, 105, à Paris, 1816.)

In the theoretical history of language, it is more than probable, that some steps will remain to exercise the ingenuity of our latest posterity. Nor will this appear surprising, when we consider how impossible it is for us to judge, from our own experience, of the intellectual processes which pass in the minds of savages. Some instincts, we know, possessed both by them and by infants (that of imitation, for example, and the use of natural signs), disappear in by far the greater number of individuals, almost entirely in the maturity of their reason. It does not seem at all improbable, that other instincts connected with the invention of speech may be confined to that state of the intellectual powers which requires their guidance; nor is it quite impossible, that some latent capacities of the understanding may be evolved by the pressure of necessity. The facility with which infants surmount so many grammatical and metaphysical difficulties, seems to me to add much weight to these conjectures.

In tracing the first steps of the invention of language, it ought never to be forgotten, that we undertake a task more similar than might at first be supposed, to that of tracing the first operations of the infant mind. In both cases, we are apt to attempt an explanation from reason alone, of what requires the co-operation of very different principles. “To trace the theoretical history of geometry, in which we know for certain, that all the transitions have depended on *reasoning* alone, is a problem which has not yet been completely solved. Nor has even any satisfactory account been hitherto given of the experimental steps by which men were gradually led to the use of iron. And yet how simple are these problems when compared with that relating to the origin and progress of language!

It is, however, less in tracing the first rudiments of speech, than in some collateral inquiries concerning the genius of different languages, that Condillac's ingenuity appears to advantage. Some of his observations, in particular, on the connection of natural signs with the growth of a systematical prosody, and on the imitative arts of the Greeks and Romans, as distinguished from those of the moderns, are new and curious; and are enlivened with a mixture of historical illustration, and of critical discussion, seldom to be met with among metaphysical writers.

But through all his researches, the radical error may, more or less, be traced, which lies at the bottom of his system;¹ and hence it is, that, with all his skill as a writer, he never elevates the imagination, or touches the heart. That he wrote with the best intentions, we have satisfactory evidence; and yet hardly a philosopher can be named, whose theories have had more influence in misleading the opinions of his contemporaries.² In

¹ A remarkable instance of this occurs in that part of Condillac's *Cours d'Etude*, where he treats of the art of writing: "Vous savez Monseigneur comment les mêmes noms ont été transportés des objets qui tombent sous les sens à ceux qui les échappent. Vous avez remarqué, qu'il y en a qui sont encore en usage dans l'un et l'autre acceptation, et qu'il y en a qui sont devenus les noms propres des choses, dont ils avoient d'abord été les signes figurés."

"Les premiers, tel que le mouvement de l'ame, son penchant, sa réflexion, donnent un corps à des choses qui n'en ont pas. Les seconds, tels que la pensée, la volonté, le désir, ne peignent plus rien, et laissent aux idées abstraites cette spiritualité qui les dérobe aux sens. Mais si le langage doit être l'image de nos pensées, on a perdu beaucoup, lorsqu'oubliant la première signification des mots, on a effacé jusqu'au traits qu'ils donnoient aux idées. Toutes les langues sont en cela plus ou moins défectueuses, toutes aussi ont des tableaux plus ou moins conservés." (*Cours d'Etude*, Tome II. p. 212. à Parme, 1775.)

Condillac enlarges on this point at considerable length; endeavouring to show, that whenever we lose sight of the analogical origin of a figurative word, we become insensible to one of the chief beauties of language. "In the word *examen*, for example, a Frenchman perceives only the proper name of one of our mental operations. A Roman attached to it the same idea, and received over and above the image of weighing and balancing. The case is the same with the words *ame* and *anima*; *pensée* and *cogitatio*."

In this view of the subject, Condillac plainly proceeded on his favourite principle, that all our notions of our mental operations are compounded of sensible images. Whereas the fact is, that the only just notions we can form of the powers of the mind are obtained by abstracting from the qualities and laws of the material world. In proportion, therefore, as the analogical origin of a figurative word disappears, it becomes a fitter instrument of metaphysical thought and reasoning. (See *Philosophical Essays*, Part I. Essay V. Chap. iii.)

² A late writer (M. de Bonald), whose philosophical opinions, in general, agree nearly with those of La Harpe, has, however, appreciated very differently, and, in my judgment, much more sagaciously, the merits of Condillac: "Condillac a eu sur l'esprit philosophique du dernier siècle, l'influence que Voltaire a prise sur l'esprit religieux, et J. J. Rousseau sur les opinions politiques. Condillac a mis de la sécheresse et de la minutie dans les esprits; Voltaire du penchant à la raillerie et à la frivolité; Rousseau les a rendus chagrins et mécontents. . . . Condillac a encore plus faussé l'esprit de la nation, parce que sa doctrine étoit enseignée dans les premières études à des jeunes gens qui n'avoient encore lu ni Rousseau, ni Voltaire, et que la

France, he very early attained to a rank and authority not inferior to those which have been so long and so deservedly assigned to Locke in England; and even in this country, his works have been more generally read and admired, than those of any foreign metaphysician of an equally recent date.

* The very general sketches to which I am here obliged to confine myself, do not allow me to take notice of various contributions to metaphysical science, which are to be collected from writers professedly intent upon other subjects. I must not, however, pass over in silence the name of Buffon, who, in the midst of those magnificent views of external nature, which the peculiar character of his eloquence fitted him so admirably to delineate, has frequently indulged himself in ingenious discussions concerning the faculties both of men and of brutes. His subject, indeed, led his attention chiefly to man, considered as an animal; but the peculiarities which the human race exhibit in their physical condition, and the manifest reference which these bear to their superior rank in the creation, unavoidably engaged him in speculations of a higher aim, and of a deeper interest. In prosecuting these, he has been accused (and perhaps with some justice) of ascribing too much to the effects of bodily organization on the intellectual powers; but he leads his reader in so pleasing a manner from matter to mind, that I have no doubt he has attracted the curiosity of many to metaphysical inquiries, who would never otherwise have thought of them. In his theories concerning the nature of the brutes, he has been commonly considered as leaning to the opinion of Descartes; but I cannot help thinking, without any good reason. Some of his ideas on the complicated operations of insects appear to me just and satisfactory; and while they account for the phenomena, without ascribing to the animal any

manière de raisonner et la direction philosophique de l'esprit s'étendent à tout." (*Recherches Phil.* Tome I. pp. 187, 188.)

The following criticism on the supposed perspicuity of Condillac's style is so just and philosophical, that I cannot refrain from giving it a place here: "Condillac est, ou paroît être, clair et méthodique; mais il faut prendre garde que la clarté des pensées, comme la transparence des objets physiques, peut tenir d'un défaut de profondeur, et que la méthode dans les écrits, qui suppose la patience de l'esprit, n'en prouve pas toujours la justesse; et moins encore la fécondité. Il y a aussi une clarté de style en quelque sorte toute matérielle, qui n'est pas incompatible avec l'obscurité dans les idées. Rien de plus facile à entendre que les mots de *sensations transformées* dont Condillac s'est servi, parce que ces mots ne parlent, qu'à l'imagination, qui se figure à volonté des transformations et des changemens. Mais cette transformation, appliquée aux opérations de l'esprit, n'est qu'un mot vide de sens; et Condillac lui-même, auroit été bien embarrassé d'en donner une explication satisfaisante. Ce philosophe me paroît plus heureux dans ses aperçus que dans ses démonstrations: La route de la vérité semble quelquefois s'ouvrir devant lui, mais retenu par la circonspection naturelle à un esprit sans chaleur, et intimidé par la faiblesse de son propre système, il n'ose s'y engager." (*Ibid.* Tome I. pp. 33, 34.)

deep or comprehensive knowledge, are far from degrading him to an insentient and unconscious machine.

In his account of the process by which the use of our external senses (particularly that of sight) is acquired, Buffon has in general followed the principles of Berkeley; and, notwithstanding some important mistakes which have escaped him in his applications of these principles, I do not know that there is anywhere to be found so pleasing or so popular an exposition of the theory of vision. Nothing certainly was ever more finely imagined, than the recital which he puts into the mouth of our first parent, of the gradual steps by which he learned the use of his perceptive organs; and although there are various parts of it which will not bear the test of a rigorous examination, it is impossible to read it without sharing in that admiration, with which we are told the author himself always regarded this favourite effusion of his eloquence.

Nor are these the only instances in which Buffon has discovered the powers of a metaphysician. His thoughts on probabilities, (a subject widely removed from his favourite studies,) afford a proof how strongly some metaphysical questions had laid hold of his curiosity, and what new lights he was qualified to throw on them, if he had allowed them to occupy more of his attention.¹ In his observations too, on the peculiar nature of mathematical evidence, he has struck into a train of the soundest thinking, in which he has been very generally followed by our later logicians.² Some particular expressions in the passage I refer to are exceptionable; but his remarks on what he calls *Vérités de Définition* are just and important: nor do I remember any modern writer, of an earlier date, who has touched on the same argument. Plato, indeed, and after him Proclus, had called the definitions of geometry *Hypotheses*; an expression which may be considered as involving the doctrine which Buffon and his successors have more fully unfolded.

What the opinions of Buffon were on those essential questions, which were then in dispute among the French philosophers, his writings do not furnish the means of judging with certainty. In his theory of *Organic Molecules*, and of *Internal Moulds*, he has been accused of entertaining views not very different from those of the ancient atomists; nor would it perhaps be easy to repel the charge, if we were not able to oppose to this wild and unintelligible hypothesis the noble and elevating strain, which in general so peculiarly characterises his descriptions of nature. The eloquence of some of the finest passages in his works has manifestly been inspired by the same sentiment which dictated to one of his

¹ See his *Essai d'Arithmétique Morale*.

² See the First Discourse prefixed to his Natural History, towards the end.

favourite authors the following just and pathetic reflection: "Le spectacle de la nature, si vivant, si animé pour ceux qui reconnoissent un Dieu, est mort aux yeux de l'athée, et dans cette grande harmonie des êtres ou tout parle de Dieu d'une voix si douce, il n'aperçoit qu'un silence éternel."¹

I have already mentioned the strong bias towards materialism, which the authors of the *Encyclopédie* derived from Condillac's comments upon Locke. These comments they seem to have received entirely upon credit, without ever being at pains to compare them with the original. Had D'Alembert exercised freely his own judgment, no person was more likely to have perceived their complete futility; and, in fact, he has thrown out various observations which strike at their very root. Notwithstanding, however, these occasional glimpses of light, he invariably reverts to the same error, and has once and again repeated it in terms as strong as Condillac or Gassendi.

The author who pushed this account of the origin of our knowledge to the most extraordinary and offensive consequences was Helvetius. His book, *De l'Esprit*, is said to have been composed of materials collected from the conversations of the society in which he habitually lived; and it has accordingly been quoted as an authentic record of the ideas then in fashion among the wits of Paris. The unconnected and desultory composition of the work certainly furnishes some intrinsic evidence of the truth of this anecdote.

According to Helvetius, as all our ideas are derived from the external senses,² the

¹ Rousseau.—In a work by Hérault de Sechelles (entitled *Voyage à Montbar, contenant des détails très intéressans sur le caractère, la personne, et les écrits de Buffon*, Paris, 1801), a very different idea of his religious creed is given from that which I have ascribed to him; but, in direct opposition to this statement, we have a letter dictated by Buffon, on his death-bed, to Madame Necker, in return for a present of her husband's book, *On the Importance of Religious Opinions*. The letter (we are told) is in the hand-writing of Buffon's son, who describes his father as then too weak to hold the pen. (*Mélanges extraits des Manuscrits de Madame Necker*. 3 Vols. Paris, 1788.)

The sublime address to the Supreme Being, with which Buffon closes his reflections on the calamities of war, seems to breathe the very soul of Fenelon. "Grand Dieu ! dont la seule présence soutient la nature et maintient l'harmonie des loix de l'univers," &c. &c. &c.

² In combating the philosophy of Helvetius, La Harpe (whose philosophical opinions seem, on many occasions, to have been not a little influenced by his private partialities and dislikes) exclaims loudly against the same principles to which he had tacitly given his unqualified approbation in speaking of Condillac. On this occasion he is at pains to distinguish between the doctrines of the two writers; asserting that Condillac considered our senses as only the *occasional* causes of our ideas, while Helvetius represented the former as the *productive* causes of the latter. (*Cours de Litterat.* Tome XV. pp. 348, 349.) But that this is by no means reconcileable with the general spirit of Condillac's works (although perhaps some detached expressions may be selected from them admitting of such an interpretation), appears sufficiently from the passages formerly quoted. In addition to these, I beg leave to transcribe the following: "Dans le système que toutes nos connoissances viennent des sens,

causes of the inferiority of the souls of brutes to those of men, are to be sought for in the difference between them with respect to bodily organization. In illustration of this remark, he reasons as follows:

“ 1. The feet of all quadrupeds terminate either in horn, as those of the ox and the deer; or in nails, as those of the dog and the wolf; or in claws, as those of the lion and the cat. This peculiar organization of the feet of these animals deprives them not only of the sense of touch, considered as a channel of information with respect to external objects, but also of the dexterity requisite for the practice of the mechanical arts.

“ 2. The life of animals, in general, being of a shorter duration than that of man, does not permit them to make so many observations, or to acquire so many ideas.

“ 3. Animals being better armed and better clothed by nature than the human species, have fewer wants, and consequently fewer motives to stimulate or to exercise their invention. If the voracious animals are more cunning than others, it is because hunger, ever inventive, inspires them with the art of stratagems to surprise their prey.

“ 4. The lower animals compose a society that flies from man, who, by the assistance of weapons made by himself, is become formidable to the strongest amongst them.

“ 5. Man is the most prolific and versatile animal upon earth. He is born and lives in every climate; while many of the other animals, as the lion, the elephant, and the rhinoceros, are found only in a certain latitude. And the more any species of animals capable of making observations is multiplied, the more ideas and the greater ingenuity is it likely to possess.

“ But some may ask (continues Helvetius), why monkeys, whose paws are nearly as dexterous as our hands, do not make a progress equal to that of man? A variety of causes (he observes) conspire to fix them in that state of inferiority in which we find them: 1.

rien n'est plus aisé que de se faire une notion exacte des idées. Car elles ne sont que des sensations ou des portions extraites de quelque sensation pour être considérées à part; ce qui produit deux sortes d'idées, les sensibles et les abstraites.” (*Traité des Systèmes*, Chap. vi.) “ Puisque nous avons vu que le souvenir n'est qu'une manière de sentir, c'est une conséquence, que les idées intellectuelles ne diffèrent pas essentiellement des sensations mêmes.” (*Traité des Sensations*, Chap. viii. § 33.) Is not this precisely the doctrine and even the language of Helvetius?

In the same passage of the *Lycée*, from which the above quotation is taken from La Harpe, there is a sweeping judgment pronounced on the merits of Locke, which may serve as a specimen of the author's competency to decide on metaphysical questions: “ Locke a prouvé autant qu'il est possible à l'homme, que l'ame est une substance simple et indivisible, et par conséquent immatérielle. Cependant, il ajoute, qu'il n'oseroit affirmer que Dieu ne puisse douer la matière de pensée. Condillac est de son avis sur le premier article, et le combat sur le second. Je suis entièrement de l'avis de Condillac, et tous les bons métaphysiciens conviennent que c'est la seule inexactitude qu'on puisse relever dans l'ouvrage de Locke.” (*Cours de Littérat.* Tome XV. p. 140.)

Men are more multiplied upon the earth. 2. Among the different species of monkeys, there are few whose strength can be compared with that of man, and, accordingly, they form only a fugitive society before the human race. 3. Monkeys being frugivorous, have fewer wants, and, therefore, less invention than man. 4. Their life is shorter. And, finally, the organical structure of their bodies keeping them, like children, in perpetual motion, even after their desires are satisfied, they are not susceptible of lassitude (*ennui*), which ought to be considered (as I shall prove afterwards) as one of the principles to which the human mind owes its improvement.

“ By combining (he adds) all these differences between the nature of man and of beast, we may understand why sensibility and memory, though faculties common to man and to the lower animals, are in the latter only sterile qualities.”¹

The foregoing passage is translated literally from a note on one of the first paragraphs of the book *De l'Esprit*; and in the sentence of the text to which the note refers, the author triumphantly asks, “ Who can doubt, that if the wrist of a man had been terminated by the hoof of a horse, the species would still have been wandering in the forest?”

Without attempting any examination of this shallow and miserable theory, I shall content myself with observing, that it is not peculiar to the philosophers of modern France. From the *Memorabilia* of Xenophon it appears, that it was current among the sophists of Greece; and the answer given it by Socrates is as philosophical and satisfactory as any thing that could possibly be advanced in the present state of the sciences.

“ And canst thou doubt, Aristodemus, if the gods take care of man? Hath not the privilege of an erect form been bestowed on him alone? Other animals they have provided with feet, by which they may be removed from one place to another; but to man they have also given the use of the hand. A tongue hath been bestowed on every other animal; but what animal, except man, hath the power of making his thoughts intelligible to others?”

“ Nor is it with respect to the body alone that the gods have shown themselves bountiful to man. Who seeth not, that he is as it were a god in the midst of this visible crea-

¹ It is not a little surprising that, in the above enumeration, Helvetius takes no notice of the want of *language* in the lower animals; a faculty without which, the multiplication of individuals could contribute nothing to the improvement of the species. Nor is this want of language in the brutes owing to any defect in the organs of speech; as sufficiently appears from those tribes which are possessed of the power of articulation in no inconsiderable a degree. It plainly indicates, therefore, some defect in those higher principles which are connected with the use of artificial signs.

tion? So far doth he surpass all animals whatever in the endowments of his body and his mind. For if the body of the ox had been joined to the mind of man, the invention of the latter would have been of little avail, while unable to execute his purposes with facility. Nor would the human form have been of more use to the brute, so long as he remained destitute of understanding. But in thee, Aristodemus, hath been joined to a wonderful soul, a body no less wonderful; and sayest thou, after this, the gods take no care of me? What wouldst thou then more to convince thee of their care?"¹

A very remarkable passage to the same purpose occurs in Galen's treatise, *De Usu Partium*. "But as of all animals man is the wisest, so *hands* are well fitted for the purposes of a wise animal. For it is not because he had hands that he is therefore wiser than the rest, as Anaxagoras alleged; but because he was wiser than the rest that he had therefore hands, as Aristotle has most wisely judged. Neither was it his hands but his reason which instructed man in the arts. The hands are only the organs by which the arts are practised."²

The contrast, in point of elevation, between the tone of French philosophy, and that of the best heathen moralists, was long ago remarked by Addison; and of this contrast, it would be difficult to find a better illustration than the passages which have just been quoted.

The disposition of ingenious men to pass suddenly from one extreme to another in matters of controversy, has, in no instance, been more strikingly exemplified than in the opposite theories concerning the nature of the brutes, which successively became fashionable in France during the last century. While the prevailing creed of French materialists leads to the rejection of every theory which professes to discriminate the rational mind from the animal principle of action, it is well known that, but a few years before, the disciples of Descartes allowed no one faculty to belong to man and brutes in common; and even went so far as to consider the latter in the light of mere machines. To this paradox the author was probably led, partly by his anxiety to elude the objection which the faculties of the lower animals have been supposed to present to the doctrine of the immortality of the soul, and partly by the difficulty of reconciling their sufferings with the Divine Goodness.

Absurd as this idea may now appear, none of the tenets of Descartes were once adopted with more implicit faith by some of the profoundest thinkers in Europe. The great Pascal admired it as the finest and most valuable article of the Cartesian system; and of the

¹ Mrs Sarah Fielding's translation.

² Galen, *De Us. Part.* l. 1. c. 8.

deep impression it made on the mind of Malebranche, a most decisive proof was exhibited by himself in the presence of Fontenelle. “ M. de Fontenelle contoit (says one of his intimate friends ¹) qu’un jour étant allé voir Malebranche aux P. P. de l’Oratoire de la Rue St Honoré, une grosse chienne de la maison, et qui étoit pleine, entra dans la salle où ils se promenoient, vint caresser le P. Malebranche, et se rouler à ses pieds. Après quelques mouvemens inutiles pour la chasser, le philosophe lui donna un grand coup de pied, qui fit jeter à la chienne un cri de douleur, et à M. de Fontenelle un cri de compassion. Eh quoi (lui dit froidement le P. Malebranche) ne savez vous pas bien que cela ne se sent point ?”

On this point Fontenelle, though a zealous Cartesian, had the good sense to dissent openly from his master, and even to express his approbation of the sarcastic remark of La Motte, *que cette opinion sur les animaux étoit une débauche de raisonnement*. Is not the same expression equally applicable to the opposite theory quoted from Helvetius ?²

From those representations of human nature which tend to assimilate to each other the faculties of man and of the brutes, the transition to atheism is not very wide. In the present instance, both conclusions seem to be the necessary corollaries of the same fundamental maxim. For if all the sources of our knowledge are to be found in the external senses, how is it possible for the human mind to rise to a conception of the Supreme Being, or to that of any other truth either of natural or of revealed religion ?

To this question Gassendi and Condillac, it cannot be doubted, were both able to return an answer, which seemed to themselves abundantly satisfactory. But how few of the multitude are competent to enter into these refined explanations ? And how much is it to be dreaded, that the majority will embrace, with the general principle, all the more obvious consequences which to their own gross conceptions it seems necessarily to involve ? Something of the same sort may be remarked in the controversy about the freedom of the human will. Among the multitudes whom Leibnitz and Edwards have made converts to the scheme of necessity, how comparatively inconsiderable is the number who have acquiesced in their subtle and ingenious attempts to reconcile this scheme with man’s accountableness and moral agency ?

¹ The Abbé Trublet in the *Mercure de Juillet*, 1757. See *Œuvres de Fontenelle*, Tome II. p. 137. Amsterdam, 1764.

² In La Fontaine’s *Discours à Madame de la Sablière* (Liv. X. Fable I.), the good sense with which he points out the extravagance of both these extremes is truly admirable. His argument (in spite of the fetters of rhyme) is stated, not only with his usual grace, but with singular clearness and precision ; and, considering the period when he wrote, reflects much honour on his philosophical sagacity.

Of the prevalence of atheism at Paris, among the higher classes, at the period of which we are now speaking, the *Memoirs* and *Correspondence* of the Baron de Grimm afford the most unquestionable proofs.¹ His friend Diderot seems to have been one of its most zealous abettors; who, it appears from various accounts, contributed to render it fashionable, still more by the extraordinary powers of his conversation, than by the odd combination of eloquence and of obscurity displayed in all his metaphysical productions.²

In order, however, to prevent misapprehension of my meaning, it is proper for me to caution my readers against supposing that *all* the eminent French philosophers of this period were of the same school with Grimm and Diderot. On this subject many of our English writers have been misled by taking for granted that to speak lightly of final causes is, of itself, sufficient proof of atheism. That this is a very rash as well as uncharitable conclusion, no other proof is necessary than the manner in which final causes are spoken of by Descartes himself, the great object of whose metaphysical writings plainly was, to establish by demonstration the existence of God. The following vindication of this part of the Cartesian philosophy has been lately offered by a French divine, and it may be ex-

¹ The *Système de la Nature* (the boldest, if not the ablest, publication of the Parisian atheists appeared in 1770. It bore on the title-page the name of Mirabaud, a respectable but not very eminent writer, who, after long filling the office of perpetual secretary to the French Academy, died at a very advanced age in 1760. (He was chiefly known as the author of very indifferent translations of *Tasso* and *Ariosto*.) It is now, however, universally admitted that Mirabaud had no share whatever in the composition of the *Système de la Nature*. It has been ascribed to various authors; nor am I quite certain, that, among those who are most competent to form a judgment upon this point, there is yet a perfect unanimity. In one of the latest works which has reached this country from France (the *Correspondance inédite de Galiani*, 1818), it seems to be assumed by the editors, as an acknowledged fact, that it proceeded from the pen of the Baron d'Holbach. The Abbé Galiani having remarked, in one of his letters to Madame Epinay, that it appeared to him to come from the same hand with the *Christianisme Devoilé* and the *Militaire Philosophe*, the editors remark in a note, "On peut rendre homage à la sagacité de l'Abbé Galiani. Le *Christianisme Devoilé* est en effet le premier ouvrage Philosophique du Baron d'Holbach. C'est en vain que la *Biographie Universelle* nous assure, d'après le témoignage de Voltaire, que cet ouvrage est de Damilaville."

Having mentioned the name of Damilaville, I am tempted to add, that the article relating to him in the *Biographie Universelle*, notwithstanding the incorrectness with which it is charged in the foregoing passage, is not unworthy of the reader's attention, as it contains some very remarkable marginal notes on the *Christianisme Devoilé* copied from Voltaire's own hand-writing.

Since writing the above note, I have seen the *Memoirs* of M. Suard, by M. Garat (Paris, 1820), in which the biographer, whose authority on this point is perfectly decisive, ascribes with confidence to Baron d'Holbach the *Système de la Nature*, and also a work entitled *La Morale et La Législation Universelle*. (Vol. I. pp. 210, 211.)

According to the same author, the Baron d'Holbach was one of Diderot's proselytes. (*Ibid.* p. 208.) His former creed, it would appear, had been very different.

² And yet Diderot, in some of his lucid intervals, seems to have thought and felt very differently. (See Note (BB).)

tended with equal justice to Buffon and many others of Descartes's successors: " Quelques auteurs, et particulièrement Leibnitz, ont critiqué cette partie de la doctrine de Descartes; mais nous la croyons irréprochable, si on veut bien l'entendre, et remarquer que Descartes ne parle que des *Fins totales* de Dieu. Sans doute, le soleil par exemple, et les étoiles, ont été faits pour l'homme, dans ce sens, que Dieu, en les créant, a eu en vue l'utilité de l'homme; et cette utilité a été sa fin. Mais cette utilité a-t-elle été l'unique fin de Dieu? Croit-on qu'en lui attribuant d'autres fins, on affoiblirait la reconnaissance de l'homme, et l'obligation ou il est de louer et de bénir Dieu dans toutes ses œuvres? Les auteurs de la vie spirituelle, les plus mystiques même, et les plus accrédités, ne l'ont pas cru." (M. l'Abbé Emery, *Editor of the Thoughts of Descartes upon Religion and Morals*, Paris, 1811, p. 79.)

As to the unqualified charge of atheism, which has been brought by some French ecclesiastics against all of their countrymen that have presumed to differ from the tenets of the Catholic church, it will be admitted, with large allowances, by every candid Presbyterian, when it is recollected that something of the same illiberality formerly existed under the comparatively enlightened establishment of England. In the present times, the following anecdote would appear incredible, if it did not rest on the unquestionable testimony of Dr Jortin: " I heard Dr B. say in a sermon, if any one denies the uninterrupted succession of bishops, I shall not scruple to call him a downright atheist. This, when I was young (Jortin adds), was sound, orthodox, and fashionable doctrine." (*Tracts*, Vol. I. p. 436.)¹

How far the effects of that false philosophy of which Grimm's correspondence exhibits so dark and so authentic a picture, were connected with the awful revolution which soon after followed, it is not easy to say. That they contributed greatly to blacken its atrocities, as well as to revolt against it the feelings of the whole Christian world, cannot be disputed. The experiment was indeed tremendous, to set loose the passions of all classes of men from the restraints imposed by religious principles; and the result exceeded, if possible, what could have been anticipated in theory. The lesson it has afforded has been dearly purchased; but let us indulge the hope that it will not be thrown away on the generations which are to come.

A prediction, which Bishop Butler hazarded many years before, does honour to his political sagacity, as well as to his knowledge of human nature;—that the spirit of irreligion

¹ See Note (CC.)

would produce, some time or other, political disorders, similar to those which arose from religious fanaticism in the seventeenth century.¹

Nearly about the time that the *Encyclopédie* was undertaken, another set of philosophers, since known by the name of *Economists*, formed themselves into an association for the purpose of enlightening the public on questions of political economy. The object of their studies seemed widely removed from all abstract discussion; but they had, nevertheless, a metaphysical system of their own, which, if it had been brought forward with less enthusiasm and exaggeration, might have been useful in counteracting the gloomy ideas then so generally prevalent about the order of the universe. The whole of their theory proceeds on the supposition that the arrangements of nature are wise and benevolent, and that it is the business of the legislator to study and co-operate with her plans in all his own regulations. With this principle, another was combined, that of the indefinite improvement of which the human mind and character are susceptible; an improvement which was represented as a natural and necessary consequence of wise laws; and which was pointed out to legislators as the most important advantage to be gained from their institutions.

These speculations, whatever opinion may be formed of their solidity, are certainly as remote as possible from any tendency to atheism, and still less do they partake of the spirit of that philosophy which would level man with the brute creation. With their practical tendency in a *political* view we are not at present concerned; but it would be an unpardonable omission, after what has been just said of the metaphysical theories of the same period, not to mention the abstract principles involved in the economical system, as a remarkable exception to the general observation. It may be questioned, too, if the authors of this system, by incorporating their ethical views with their political disquisitions,

¹ "Is there no danger that all this may raise somewhat like that levelling spirit, upon atheistical principles, which, in the last age, prevailed upon enthusiastic ones? Not to speak of the possibility, that different sorts of people may unite in it upon these contrary principles." (*Sermon preached before the House of Lords, January 30, 1741.*)

As the fatal effects of both these extremes have, in the course of the two last centuries, been exemplified on so gigantic a scale in the two most civilized countries of Europe, it is to be hoped that mankind may in future derive some salutary admonitions from the experience of their predecessors. In the meantime, from that disposition common both to the higher and lower orders to pass suddenly from one extreme to another, it is at least possible that the strong reaction produced by the spirit of impiety during the French Revolution may, in the first instance, impel the multitude to something approaching to the puritanical fanaticism and frenzy of the Cromwellian Commonwealth.

did not take a more effectual step towards discountenancing the opinions to which they were opposed, than if they had attacked them in the way of direct argument.¹

On the metaphysical theories which issued from the French press during the latter half of the last century, I do not think it necessary for me to enlarge, after what I have so fully stated in some of my former publications. To enter into details with respect to particular works would be superfluous, as the remarks made upon any one of them are nearly applicable to them all. The excellent writings of M. Prevost, and of M. Degerando, will, it is to be hoped, gradually introduce into France a sounder taste in this branch of philosophy.² At present, so far as I am acquainted with the state of what is called *Idéologie* in that country, it does not appear to me to furnish much matter either for the instruction or amusement of my readers.

The works of Rousseau have, in general, too slight a connection with metaphysical science, to come under review in this part of my discourse. But to his *Emile*, which has been regarded as a supplement to Locke's *Treatise on Education*, some attention is justly due, on account of various original and sound suggestions on the management of the infant mind, which, among many extravagancies, savouring strongly both of intellectual and moral insanity, may be gathered by a sober and discriminating inquirer. The estimate of the merits of this work, formed by Mr Gray, appears to me so just and impartial, that I shall adopt it here without a comment.

"I doubt" (says he, in a letter to a friend) "you have not yet read Rousseau's *Emile*. Every body that has children should read it more than once; for though it abounds with his usual glorious absurdity, though his general scheme of education be an impracticable

¹ For some other observations on the Ethical principles assumed in the Economical system, see *Elements of the Philosophy of the Human Mind*, Vol. II. Chap. iv. Section 6, § 1, towards the end.

² Some symptoms of such a reformation are admitted already to exist, by an author decidedly hostile to all philosophical systems. "Bacon, Locke, Condillac, cherchoient dans nos sens l'origine de nos idées; Helvetius y a trouve nos idées elles-mêmes. Juger, selon ce philosophe, n'est autre chose que sentir.* Aujourd'hui les bons esprits, éclairés par les événemens sur la secrète tendance de toutes ces opinions, les ont soumises à un examen plus sévère. La transformation des sensations en idées ne paroît plus qu'un mot vide sens. On trouve que l'homme statue ressemble un peu trop à l'homme machine, et Condillac est modifié ou même combattu sur quelques points, par tous ceux qui s'en servent encore dans l'enseignement philosophique. (*Recherches Philosophiques*, &c. par M. de Bonald, Tome I. pp. 34, 35.)

* I was somewhat surprised, in looking over very lately the *Principia of Descartes*, to find (what had formerly escaped me), that the mode of speaking objected to in the above paragraph may plead in its favour the authority of that philosopher: "Cogitationis nomine, intelligo illa omnia, quæ nobis consciis in nobis fiunt, quatenus eorum in nobis conscientia est: Atque ita non modo intelligere, velle, imaginari, sed etiam sentire, idem est hic quod cogitare." (*Princ. Phil.* p. 2.) Dr Reid, too, has said that "the sensation of colour is a sort of thought" (*Inquiry*, Chap. vi. § 4); but no names, how great soever, can sanction so gross an abuse of language.

After all, there is some difference between saying, that sensation is a sort of thought, and that thought is a sort of sensation.

chimera, yet there are a thousand lights struck out, a thousand important truths better expressed than ever they were before, that may be of service to the wisest men. Particularly, I think he has observed children with more attention, knows their meaning, and the working of their little passions, better than any other writer. As to his religious discussions, which have alarmed the world, and engaged their thoughts more than any other parts of his book, I set them all at nought, and wish they had been omitted." (Gray's *Works* by Mason, Letter 49.)

The most valuable additions made by French writers to the Philosophy of the Human Mind are to be found, not in their systematical treatises on metaphysics, but in those more popular compositions, which, professing to paint the prevailing manners of the times, touch occasionally on the varieties of intellectual character. In this most interesting and important study, which has been hitherto almost entirely neglected in Great Britain, France must be allowed not only to have led the way, but to remain still unrivalled. It would be endless to enumerate names; but I must not pass over those of Vauvenargues²

¹ Many precious hints connected with it may, however, be collected from the writings of Lord Bacon, and a few from those of Mr Locke. It does not seem to have engaged the curiosity of Mr Hume in so great a degree as might have been expected from his habits of observation, and extensive intercourse with the world. The objects of Dr Reid's inquiries led him into a totally different track.

Among German writers, Leibnitz has occasionally glanced with a penetrating eye at the varieties of genius, and it were to be wished that he had done so more frequently. How far his example has been followed by his countrymen in later times, I am unable to judge, from my ignorance of their language.

A work expressly on this subject was published by a Spanish physician (Huarte) in the seventeenth century. A French translation of it, printed at Amsterdam in 1672, is now lying before me. It is entitled, *Examen des Esprits pour les Sciences. Ou se montrent les differences des Esprits, qui se trouvent parmi les hommes et a quel genre de Science un chacun est propre en particulier.* The execution of this work certainly falls far short of the expectations raised by the title; but (allowances being made for the period when it was written) it is by no means destitute of merit, nor unworthy of the attention of those who may speculate on the subject of Education. For some particulars about its contents, and also about the author, see Bayle's *Dictionary*, Art. *Huarte*; and *The Spectator*, No. 30.

² The Marquis de Vauvenargues, author of a small volume, entitled *Introduction à la Connoissance de l'Esprit Humain*. He entered into the army at the age of eighteen, and continued to serve for nine years; when, having lost his health irrecoverably, in consequence of the fatigues he underwent in the memorable retreat from Prague, in December 1742, he resolved to quit his profession, in the hope of obtaining some diplomatic employment better suited to his broken constitution. Soon after he was attacked by the small-pox, which unfortunately turned out of so malignant a kind, as to disfigure his countenance, and deprive him almost totally of sight. He died in 1747, at the age of thirty-two. The small volume above mentioned was published the year before his death. It bears everywhere the marks of a powerful, original, and elevated mind; and the imperfect education which the author appears to have received gives it an additional charm, as the genuine result of his own unsophisticated reflections.

Marmontel has given a most interesting picture of his social character: "En le lisant, je crois encore l'entendre, et je ne sais si sa conversation n'avait pas même quelque chose de plus animé, de plus délicat

and Duclos.¹ Nor can I forbear to remark, in justice to an author whom I have already very freely censured, that a variety of acute and refined observations on the different modifications of genius may be collected from the writings of Helvetius. The soundness of some of his distinctions may perhaps be questioned; but even his attempts at classification may serve as useful guides to future observers, and may supply them with a convenient nomenclature, to which it is not always easy to find corresponding terms in other languages. As examples of this it is sufficient to mention the following phrases: *Esprit juste*, *Esprit borné*, *Esprit étendu*, *Esprit fin*, *Esprit délié*, *Esprit de lumière*. The peculiar richness of the French tongue in such appropriate expressions (a circumstance, by the way, which not unfrequently leads foreigners to overrate the depth of a talkative Frenchman) is itself a proof of the degree of attention which the ideas they are meant to convey have attracted in that country among the higher and more cultivated classes.

The influence, however, of the philosophical spirit on the general habits of thinking among men of letters in France, was in no instance displayed to greater advantage, than in the numerous examples of *theoretical* or *conjectural* history, which appeared about the middle of last century. I have already mentioned the attempts of Condillac and others, to trace upon this plan the first steps of the human mind in the invention of language. The same sort of speculation has been applied with greater success to the mechanical and other necessary arts of civilized life; and still more ingeniously and happily to the different branches of pure and mixed mathematics. To a philosophical mind, no study certainly can be more delightful than this species of history; but as an organ of instruction, I am not disposed to estimate its practical utility so highly as D'Alembert. It does

que ses divins écrits." And, on a different occasion, he speaks of him thus: "Doux, sensible, compatissant, il tenait nos âmes dans ses mains. Une sérénité inaltérable dérobait ses douleurs aux yeux de l'amitié. Pour soutenir l'adversité, on n'avait besoin que de son exemple; et témoin de l'égalité de son âme, on n'osait être malheureux avec lui."

If the space allotted to him in this note should be thought to exceed what is due to his literary eminence, the singular circumstances of his short and unfortunate life, and the deep impression which his virtues, as well as his talents, appear to have left on the minds of all who knew him, will, I trust, be a sufficient apology for my wish to add something to the celebrity of a name, hitherto, I believe, very little known in this country.

¹ The work of Duclos, here referred to, has for its title, *Considerations sur les Mœurs de ce Siècle*. Gibbon's opinion of this book is, I think, not beyond its merits: "L'ouvrage en général est bon. Quelques chapitres (le rapport de l'esprit et du caractère) me paroissent excellent." (*Extrait du Journal*.)

I have said nothing of La Rochefoucauld and La Bruyère, as their attention was chiefly confined to manners, and to moral qualities. Yet many of their remarks show, that they had not wholly overlooked the diversities among men in point of intellect. An observer of sagacity equal to their's might, I should think, find a rich field of study in this part of human nature, as well as in the other.

not seem to me at all adapted to interest the curiosity of novices; nor is it so well calculated to engage the attention of those who wish to enlarge their scientific knowledge, as of persons accustomed to reflect on the phenomena and laws of the intellectual world.

Of the application of theoretical history, to account for the diversities of laws and modes of government among men, I shall have occasion afterwards to speak. At present I shall only remark the common relation in which all such researches stand to the Philosophy of the Human Mind, and their common tendency to expand and to liberalize the views of those who are occupied in the more confined pursuits of the subordinate sciences.

After what has been already said of the general tone of French philosophy, it will not appear surprising, that a system so mystical and spiritual as that of Leibnitz never struck its roots deeply in that country. A masterly outline of its principles was published by Madame du Chatelet, at a period of her life when she was an enthusiastic admirer of the author; and a work on such a Subject, composed by a lady of her rank and genius, could not fail to produce at first a very strong sensation at Paris; but not long after she herself abandoned the German philosophy, and became a zealous partizan of the Newtonian school. She even translated into French, and enriched with a commentary, the *Principia* of Newton; and by thus renouncing her first faith, contributed more to discredit it, than she had previously done to bring it into fashion. Since that time, Leibnitz has had few, if any, disciples in France, although some of his peculiar tenets have occasionally found advocates there, among those who have rejected the great and leading doctrines, by which his system is more peculiarly characterized. His opinions and reasonings in particular, on the necessary concatenation of all events, both physical and moral (which accorded but too well with the philosophy professed by Grimm and Diderot), have been long incorporated with the doctrines of the French materialists, and they have been lately adopted and sanctioned, in all their extent, by a living author, the unrivalled splendour of whose mathematical genius may be justly suspected, in the case of some of his admirers, to throw a false lustre on the dark shades of his philosophical creed.¹

¹ “ Les événemens actuels ont avec les précédens une liaison fondée sur le principe évident, qu’une chose ne peut pas commencer, d’être, sans une cause qui la produise. Cet axiome, connu sous le nom de *principe de la raison suffisante*, s’étend aux actions même que l’on juge indifférentes. La volonté la plus libre ne peut, sans un motif déterminant, leur donner naissance; car si, toutes les circonstances de deux positions étant exactement semblables, elle agissoit dans l’une et s’abstenoit d’agir dans l’autre, son choix seroit un effet sans cause; * elle seroit alors, dit Leibnitz, le *hasard aveugle* des Epicuriens. L’opinion contraire est une illusion de l’esprit qui per-

* The impropriety of this language was long ago pointed out by Mr Hume. “ They are still more frivolous, who say, that every effect must have a cause, because it is implicit in the very idea of effect. Every effect naturally presupposes a cause; effect being a relative term, of which cause is the co-relative. The true state of the question is, whether every object, which begins to exist, must owe its existence to a cause.” (*Treatise of Human Nature*, Vol. I. p. 147.)

Notwithstanding, however, this important and unfortunate coincidence, no two systems can well be imagined more strongly contrasted on the whole, than the lofty metaphysics of Leibnitz, and that degrading theory concerning the origin of our ideas, which has been fashionable in France since the time of Condillac. In proof of this, I have only to refer to the account of both, which has been already given.

The same contrast, it would appear, still continues to exist between the favourite doctrines of the German and of the French schools. "In the French empiricism" (says a most impartial, as well as competent judge, M. Ancillon), "the faculty of feeling, and the faculty of knowing, are one and the same. In the new philosophy of Germany, there is no faculty of knowing, but reason. In the former, taking our departure from individuals, we rise by degrees to ideas, to general notions, to principles. In the latter, be-

dant de vue les raisons fugitives du choix de la volonté dans les choses indifférentes, se persuade qu'elle s'est déterminée d'elle même et sans motifs.

"Nous devons donc envisager l'état présent de l'univers comme l'effet de son état antérieur et comme la cause de celui qui va suivre. Une intelligence qui pour un instant donné connoitroit toutes les forces dont la nature est animée, et la situation respective des êtres qui la composent, si d'ailleurs elle étoit assez vaste pour soumettre ces données à l'analyse, embrasseroit dans la même formule, les mouvemens des plus grands corps de l'univers et ceux du plus léger atome. Rien ne seroit incertain pour elle, et l'avenir comme le passé, seroit présent à ses yeux." (*Essai Philosophique sur les Probabilités*, par Laplace.)

Is not this the very spirit of the *Theodicæ* of Leibnitz, and, when combined with the other reasonings in the *Essay on Probabilities*, the very essence of Spinozism?

This, indeed, is studiously kept by the author out of the reader's view; and hence the facility with which some of his propositions have been admitted by many of his *mathematical* disciples, who, it is highly probable, were not aware of the consequences which they necessarily involve.

I cannot conclude this note without recurring to an observation ascribed in the above quotation from Laplace to Leibnitz, "that the *blind chance* of the Epicureans involves the supposition of an effect taking place without a cause." This, I apprehend, is a very incorrect statement of the philosophy taught by Lucretius, which nowhere gives the slightest countenance to such a supposition. The distinguishing tenet of this sect was, that the order of the universe does not imply the existence of *intelligent* causes; but may be accounted for by the active powers belonging to the atoms of matter; which active powers, being exerted through an indefinitely long period of time, *might* produce, nay, *must* have produced, exactly such a combination of things, as that with which we are surrounded. This, it is evident, does not call in question the necessity of a cause to produce every effect, but, on the contrary, virtually assumes the truth of that axiom. It only excludes from these causes the attribute of intelligence. It is in the same way when I apply the words blind chance (*hazard aveugle*) to the throw of a die, I do not mean to deny that I am ultimately the cause of the particular event that is to take place; but only to intimate that I do not here act as a *designing* cause, in consequence of my ignorance of the various accidents to which the die is subjected, while shaken in the box. If I am not mistaken, this *Epicurean Theory* approaches very nearly to the scheme, which it is the main object of the *Essay on Probabilities* to inculcate; and, therefore, it was not quite fair in Laplace to object to the supposition of man's free agency, as favouring those principles which he himself was labouring indirectly to insinuate.

From a passage in Plato's *Sophist*, it is very justly inferred by Mr Gray, that, according to the common opinion then entertained, "the creation of things was the work of blind unintelligent matter; whereas the con-

ginning with what is most general, or rather with what is universal, we descend to individual existences, and to particular cases. In the one, what we see, what we touch, what we feel, are the only realities. In the other nothing is real, but what is invisible and purely intellectual."

"Both these systems (continues M. Ancillon) result from the exaggeration of a sound principle. They are both true and both false in part; true in what they admit, false in what they reject. All our knowledge begins, or appears to begin, in sensation; but it does not follow from this that it is all derived from sensation, or that sensation constitutes its whole amount. The proper and innate activity of the mind has a large share in the origin of our *representations*, our sentiments, our ideas. Reason involves principles which she does not borrow from without, which she owes only to herself, which the impressions of the senses call forth from their obscurity, but which, far from owing their origin to sensations, serve to appreciate them, to judge of them, to employ them as instruments. It would be rash, however, to conclude from hence, that there is no certainty but in reason, that reason alone can seize the mystery of existences, and the intimate nature of beings, and that experience is nothing but a vain appearance, destitute of every species of reality."¹

With this short and comprehensive estimate of the new German philosophy, pronounced by one of the most distinguished members of the Berlin Academy, I might perhaps be pardoned for dismissing a subject, with which I have, in some of my former publications, acknowledged myself (from my total ignorance of the German language) to be very imperfectly acquainted; but the impression which it produced for a few years in England

trary was the result of philosophical reflection and disquisition believed by a few people only." (*Gray's Works* by Matthias, Vol. II. p. 414.) On the same subject, see Smith's *Posthumous Essays*, p. 106.

¹ *Mélanges de Littérature et de Philosophie*, par F. Ancillon, Préface. (à Paris, 1809.) The intimacy of M. Ancillon's literary connections both with France and with Germany entitle his opinions on the respective merits of their philosophical systems to peculiar weight. If he anywhere discovers a partiality for either, the modest account which he gives of himself would lead us to expect his leaning to be in favour of his countrymen. "Placé entre la France et l'Allemagne, appartenant à la première par la langue dans laquelle je hasarde d'écrire, à la seconde par ma naissance, mes études, mes principes, mes affections, et j'ose le dire, par la couleur de ma pensée, je desirerois pouvoir servir de médiateur littéraire, ou d'interprète philosophique entre les deux nations."

In translating from M. Ancillon, the passage quoted in the text, I have adhered as closely as possible to the words of the original; although I cannot help imagining that I could have rendered it still more intelligible to the English reader by laying aside some of the peculiarities of his German phraseology. My chief reason for retaining these, was to add weight to the strictures which a critic, so deeply tinctured with the German habits of thinking and of writing, has offered, on the most prominent faults of the systems in which he had been educated.

(more particularly while our intercourse with the continent was interrupted), makes it proper for me to bestow on it a little more notice in this Dissertation, than I should otherwise have judged necessary or useful.

SECTION VII.

*Kant and other Metaphysicians of the New German School.*¹

THE long reign of the Leibnitzian Philosophy in Germany was owing, in no inconsiderable degree, to the zeal and ability with which it was taught in that part of Europe, for nearly half a century, by his disciple Wolfius,² a man of little genius, originality, or taste, but whose extensive and various learning, seconded by a methodical head,³ and by an

¹ My ignorance of German would have prevented me from saying anything of the philosophy of Kant, if the extraordinary pretensions with which it was at first brought forward in this island, contrasted with the total oblivion into which it soon after very suddenly fell, had not seemed to demand some attention to so wonderful a phenomenon in the literary history of the eighteenth century. My readers will perceive that I have taken some pains to atone for my inability to read Kant's works in the original, not only by availing myself of the Latin version of Born, but by consulting various comments on them which have appeared in the English, French, and Latin languages. As commentators, however, and even translators, are not always to be trusted to as unexceptionable interpreters of their authors' opinions, my chief reliance has been placed on one of Kant's own compositions in Latin; his Dissertation *De Mundi Sensibilis atque Intelligibilis Forma et Principiis*, which he printed as the subject of a public disputation, when he was candidate for a Professorship in the University of Königsberg. It is far from being improbable, after all, that I may, in some instances, have misapprehended his meaning, but I hope I shall not be accused of wilfully misrepresenting it. Where my remarks are borrowed from other writers, I have been careful in referring to my authorities, that my reader may judge for himself of the fidelity of my statements. If no other purpose, therefore, should be answered by this part of my work, it may at least be of use by calling forth some person properly qualified to correct any mistakes into which I may involuntarily have fallen; and in the meantime, may serve to direct those who are strangers to German literature, to some of the comments on this philosophy which have appeared in languages more generally understood in this country.

² Born 1679. Died 1754.

³ The display of method, however, so conspicuous in all the works of Wolfius, will often be found to amount to little more than an awkward affectation of the phraseology and forms of mathematics, in sciences where they contribute nothing to the clearness of our ideas, or the correctness of our reasonings. This affectation, which seems to have been well adapted to the taste of Germany at the time when he wrote, is now one of the chief causes of the neglect into which his writings have fallen. Some of them may be still usefully consulted as dictionaries, but to read them is impossible. They amount to about forty quarto volumes, twenty-three of which are in Latin, the rest in German.

incredible industry and perseverance, seem to have been peculiarly fitted to command the admiration of his countrymen. Wolfius, indeed, did not profess to follow implicitly the opinions of his master, and, on some points, laid claim to peculiar ideas of his own; but the spirit of his philosophy is essentially the same with that of Leibnitz,¹ and the particulars in which he dissented from him are too trifling to deserve any notice in the history of literature.²

The high reputation so long maintained by Wolfius in Germany suggested, at different times, to the book-makers at Paris, the idea of introducing into France the philosophy which he taught. Hence a number of French abridgments of his logical and metaphysical writings. But an attempt, which had failed in the hands of Madame du Chatelet, was not likely to succeed with the admirers and abridgers of Wolfius.³

In his own country the reputation of Wolfius is not yet at an end. In the preface to Kant's *Critique of Pure Reason*, he is called "Summus omnium dogmaticorum Philosophus." *Kantii Opera ad Philosophiam Criticam*, Vol. I. Præf. Auctoris Posterior, p. xxxvi. Latine Vertit. Fred. Born. Lipsiæ, 1796.) And by one of Kant's best commentators, his name is advantageously contrasted with that of David Hume: "Est autem scientifica methodus aut dogmatica, aut sceptica. Primi generis autorem celeberrimum Wolfium, alterius Davidem Humum nominasse sat est." (*Expositio Philos. Criticæ*. Autore Conrado Friderico a Schmidt-Phiseldek. Hafniæ, 1796.)

¹ On the great question of Free Will, Wolfius adopted implicitly the principles of the *Theodicea*; considering man merely in the light of a machine; but (with the author of that work) dignifying this machine by the epithet *spiritual*. This language, which is still very prevalent among German philosophers, may be regarded as a relic of the doctrines of Leibnitz and of Wolfius; and affords an additional proof of the difficulty of eradicating errors sanctioned by illustrious and popular names.

When the system of Pre established Harmony was first introduced by Wolfius into the University of Halle it excited an alarm which had very nearly been attended with fatal consequences to the professor. The following anecdote on the subject is told by Euler: "Lorsque du temps du feu Roi de Prusse, M. Wolf enseignoit à Halle le système de l'Harmonie Pré-établie, le Roi s'informa de cette doctrine, qui faisoit grand bruit alors; et un courtisan répondit à sa Majesté, que tous les soldats, selon cette doctrine, n'étoient que des machines; que quand il en désertoit c'étoit une suite nécessaire de leur structure, et qu'on avoit tort par conséquent de les punir, comme on l'auroit si on punissoit une machine pour avoir produit tel ou tel mouvement. Le Roi se facha si fort sur ce rapport, qu'il donna ordre de chasser M. Wolf de Halle sous peine d'être pendu s'il s'y trouvoit au bout de 24 heures. Le philosophe se refugia alors à Marbourg, où je lui ai parlé peu de temps après." (*Lettres à une Princesse d'Allemagne*, Lettre 84^{me}.) We are informed by Condorcet, that some reparation was afterwards made for this injustice by Frederic the Great. "Le Roi de Prusse, qui ne croit pas pourtant à l'Harmonie Pré-établie, s'est empressé de rendre justice à Wolf dès le premier jour de son regne."

² Among other novelties affected by Wolfius, was a new modification of the Theory of the Monads. A slight outline of it, but quite sufficient, & should suppose, to gratify the curiosity of most readers, may be found in Euler's *Letter to a German Princess*.

³ To what was before remarked, of the opposition in matters of philosophy between the taste of the French and that of the Germans, I shall here add a short passage from an author intimately acquainted with the literature of both nations.

From the time of Wolfius till the philosophy of Kant began to attract general notice, I know of no German metaphysician whose speculations seem to have acquired much celebrity in the learned world.¹ Lambert² is perhaps the most illustrious name which occurs during this interval. As a mathematician and natural philosopher, his great merits are universally known and acknowledged, but the language in which his metaphysical and logical works were written, has confined their reputation within a comparatively narrow circle. I am sorry that I cannot speak of these from my own knowledge; but I have heard them mentioned in terms of the highest praise, by some very competent judges, to whose testimony I am disposed to give the greater credit, from the singular vein of originality which runs through all his mathematical and physical publications.³

“L'école Allemande reconnoit Leibnitz pour chef. Son fameux disciple Wolf régna dans les universités pendant près d'un demi siècle avec une autorité non contestée. On connoit en France cette philosophie par un grand nombre d'abregés dont quelque-uns sont faits par des auteurs qui seuls auroient suffi pour lui donner de la célébrité.

“Malgré l'appui de tous ces noms, jamais en France cette philosophie ne s'est soutenue même quelques instans. La profondeur apparente des idées, l'air d'ensemble et de système, n'ont jamais pu y suppléer à ce qui a paru lui manquer pour en faire une doctrine solide et digne d'être accueillie. Outre quelque défaut de clarté, qui probablement en a écarté des esprits pour qui cette qualité de style et de la pensée est devenue un heureux besoin, la forme sous laquelle elle se présente a rebuté bien des lecteurs. Quoi qu'aient pu faire les interprètes, il a toujours percé quelque chose de l'appareil incommode qui l'entoure à son origine. Condillac tourne plus d'une fois en ridicule ces formes et ce jargon scientifique, et il s'applique à montrer qu'ils ne sont pas plus propres à satisfaire la raison que le goût. Il est au moins certain, que le lecteur Français les repousse par instinct, et qu'il y trouve un obstacle très difficile à surmonter.” (*Reflexions sur les Œuvres Posthumes d'Adam Smith*, par M. Prevost de Genève, à Paris, 1794.)

¹ Madame de Staël mentions Lessing, Hemsterhuis, and Jacobi, as precursors of Kant in his philosophical career. She adds, however, that they had no school, since none of them attempted to found any system; but they began the war against the doctrines of the Materialists. (*Allemagne*, Tome III. p. 98.) I am not acquainted with the metaphysical works of any of the three. Those of Hemsterhuis, who wrote wholly in French, were, I understand, first published in a collected form at Paris, in 1792. He was son of the celebrated Greek scholar and critic, Tiberius Hemsterhusius, Professor of Latin Literature at Leyden.

² Born at Mulhausen in Alsace in 1728. Died at Berlin in 1777.

³ The following particulars, with respect to Lambert's literary history, are extracted from a *Memoir* annexed by M. Prevost to his translation of Mr Smith's *Posthumous Works*: “Cet ingénieux et puissant Lambert, dont les mathématiques, qui lui doivent beaucoup, ne purent épuiser les forces, et qui ne toucha aucun sujet de physique ou de philosophie rationnelle, sans le couvrir de lumière. Ses lettres cosmologiques, qu'il écrivit par forme de délassement, sont pleines d'idées sublimes, entées sur la philosophie la plus saine et la plus savante tout-à-la-fois. Il avoit aussi dressé sous le titre d'*Architectonique* un tableau des principes sur lesquels se fondent les connoissances humaines. Cet ouvrage au jugement des hommes les plus versés dans l'étude de leur langue, n'est pas exempt d'obscurité. Elle peut tenir en partie à la nature du sujet. Il est à regretter que sa logique, intitulé *Organon*, ne soit traduite ni en Latin, ni en Français, ni je pense en aucune langue. Un extrait bien fait de cet ouvrage, duquel on écarteroit ce qui répugne au goût national, exciteroit l'attention des philosophes, et la por-

The *Critique of Pure Reason* (the most celebrated of Kant's metaphysical works) appeared in 1781.¹ The idea annexed to the title by the author, is thus explained by himself: " Criticam rationis puræ non dico censuram librorum et Systematum, sed facultatis rationalis in universum, respectu cognitionum omnium, ad quas, ab omni experientia libera, possit anniti, proinde, dijudicationem possibilitatis aut impossibilitatis metaphysicæ in genere, constitutionemque tum fontium, tum ambitus atque compagis tum vero terminorum illius, sed cuncta hæc ex principiis." (Kantii, *Opera ad Philosophiam Criticam*, Vol. I. Præfatio Auctoris Prior. pp. xi. xii.) To render this somewhat more intelligible, I shall subjoin the comment of one of his intimate friends,² whose work, we are informed by Dr Willich, had received the sanction of Kant himself. " The aim of Kant's *Critique* is no less than to lead Reason to the true knowledge of itself; to examine the titles upon which it founds the supposed possession of its metaphysical knowledge; and by means of this examination to mark the true limits, beyond which it cannot venture to speculate, without wandering into the empty region of pure fancy." The same author adds, " The whole *Critique of Pure Reason* is established upon this principle, *that there is a free reason, independent of all experience and sensation.*"

When the *Critique of Pure Reason* first came out, it does not seem to have attracted much notice,³ but such has been its subsequent success, that it may be regarded (according

teroit sur une multitude d'objets qu'ils se sont accoutumés à regarder avec indifférence." (Prevost. Tome II. pp. 267, 268.)

In the article *Lambert*, inserted in the twenty-third volume of the *Biographie Universelle* (Paris, 1819), the following account is given of Lambert's logic: " Wolf, d'après quelques indications de Leibnitz, avoit retiré de l'oubli la syllogistique d'Aristote, science que les scholastiques avoient tellement avilie que ni Bacon ni Locke n'avoient osé lui accorder un regard d'intérêt. Il étoit réservé à Lambert de la montrer sous le plus beau jour et dans la plus riche parure. C'est ce qu'il a fait dans son *Novum Organon*, ouvrage qui est un des principaux titres de gloire de son auteur." From the writer of this article (M. Servois) we farther learn, that the *Novum Organon* of Lambert was translated into Latin from the German original by a person of the name of Pfeiderer, and that this translation was in the hands of an English nobleman (the late Earl of Stanhope) as lately as 1782. I quote the words of M. Servois, in the hope that they may attract some attention to the manuscript, if it be still in existence. The publication of it would certainly be a most acceptable present to the learned world. " D'après le conseil de Le Sage de Geneve, l'ouvrage fut traduit en Latin par Pfeiderer, aux frais d'un savant Italien, cette traduction passa, on ne sait comment, entre les mains de Milord Mahon qui la possédoit encore en 1782; on ignore quel est son sort ulterieur."

¹ Kant was born at Königsberg, in Prussia, in 1724. He died in 1804.

² Mr John Schulze, an eminent divine at Königsberg, author of the *Synopsis of the Critical Philosophy*, translated by Dr Willich, and inserted in his *Elementary View of Kant's Works*. (See pp. 42, 43.)

³ " Il se passa quelque tems après la première publication de la *Critique de la Pure Raison*, sans qu'on fit beaucoup d'attention à ce livre, et sans que la plupart de philosophes, passionés pour l'éclectisme

to Madame de Staël)¹ “as having given the impulse to all that has been since done in Germany, both in literature and in philosophy.” (*Allemagne*, Vol. III. pp. 68, 69.)

soupçonnassent seulement la grande révolution que cet ouvrage et les productions suivantes de son auteur devoient opérer dans la science.” (Buhle, *Hist. de la Phil. Mod.* Tom. VI. p. 573. Paris, 1816.)

As early, however, as the year 1783, the philosophy of Kant appears to have been adopted in some of the German schools. The ingenious M. Trembley, in a memoir then read before the Academy of Berlin, thus speaks of it: “La philosophie de Kant, qui a la honte de l'esprit humain, paroît avoir acquis tant de faveur dans certaines écoles.” (*Essai sur les Préjugés*. Reprinted at Neuchâtel in 1790.)

We are farther told by Buhle, that the attention of the public to Kant's *Critique of Pure Reason* was first attracted by an excellent analysis of the work, which appeared in the *General Gazette of Literature*, and by the *Letters on Kant's Philosophy*, which Reinhold inserted in the *German Mercury*. (Buhle, Tom. VI. p. 573.) Of this last philosopher, who appears, in the first instance, to have entered with enthusiasm into Kant's views, and who afterwards contributed much to open the eyes of his countrymen to the radical defects of his system, I shall have occasion to speak hereafter. Degerando, as well as Buhle, bestows high praise not only on his clearness, but on his eloquence, as a writer in his own language. “Il a traduit les oracles Kantians dans une langue élégante, harmonieuse, et pure * * * Il a su exprimer avec un langage éloquent, des idées jusqu'alors inintelligibles,” &c. (*Histoire Comparée*, &c. Tom. II. p. 271.) That this praise is not undeserved I am very ready to believe, having lately had an opportunity (through the kindness of my learned and revered friend Dr Parr) of reading in the Latin version of Fredericus Gottlob Born, Reinhold's principal work, entitled *Periculum Novæ Theoriæ Facultatis Representatiæ Humanæ*. In point of perspicuity, he appears to me to be greatly superior to Kant; and of this I conceive myself to be not altogether incompetent to judge, as the Latin versions of both authors are by the same hand.

¹ The following quotation, from the advertisement prefixed to Madame de Staël's posthumous work (*Considérations sur la Révolution Française*), will at once account to my readers for the confidence with which I appeal to her historical statements on the subject of German philosophy. Her own knowledge of the language was probably not so critically exact, as to enable her to enter into the more refined details of the different systems which she has described; but her extraordinary penetration, joined to the opportunities she enjoyed of conversing with all that was then most illustrious in Germany, qualified her in an eminent degree to seize and to delineate their great outlines. And if, in executing this task, any considerable mistakes could have been supposed to escape her, we may be fully assured, that the very accomplished person, to whose revision we learn that her literary labours at this period of her life were submitted, would prevent them from ever meeting the public eye. I except, of course, those mistakes into which she was betrayed by her admiration of the German school. Of some of the most important of these, I shall take notice as I proceed; a task which I feel incumbent on me, as it is through the medium of her book that the great majority of English readers have acquired all their knowledge of the new German philosophy, and as her name and talents have given it a temporary consequence in this country which it could not otherwise have acquired.

“Le travail des éditeurs s'est borné uniquement à la révision des épreuves, et à la correction de ces légères inexactitudes de style, que échappent à la vue dans le manuscrit le plus soigné. Ce travail c'est fait sous les yeux de M. A. W. de Schlegel, dont la rare supériorité d'esprit et de savoir justifie la confiance avec laquelle Madame de Staël le consultoit dans tous ses travaux littéraires, autant que son honorable caractère mérite l'estime et l'amitié qu'elle n'a pas cessé d'avoir pour lui pendant une liaison de treize années.”

If any farther apology be necessary for quoting a French lady as an authority on German metaphysics, an obvious one is suggested by the extraordinary and well merited popularity of her *Allemagne* in this country. I

“ At the epoch when this work was published (continues the same writer), there existed among thinking men only two systems concerning the human understanding : The one, that of Locke, ascribed all our ideas to our sensations ;¹ the other, that of Descartes and of Leibnitz, had for its chief objects to demonstrate the spirituality and activity of the soul, the freedom of the will,² and, in short, the whole doctrines of the idealists. . . .

do not know, if, in any part of her works, her matchless powers have been displayed to greater advantage. Of this no stronger proof can be given, than the lively interest she inspires, even when discussing such systems as those of Kant and of Fichte.

¹ That this is a very incorrect account of Locke's philosophy, has been already shown at great length ; but in this mistake Madame de Stael has only followed Leibnitz, and a very large proportion of the German philosophers of the present day. “ The philosophy of sensation (says Frederick Schlegel), which was unconsciously bequeathed to the world by Bacon, and reduced to a methodical shape by Locke, first displayed in France the true immorality and destructiveness of which it is the parent, and assumed the appearance of a perfect system of Atheism.” (*Lectures on the History of Literature*, from the German of Fred. Schlegel. Edm. 1818, Vol. II p. 22.) It is evident, that the system of Locke is here confounded with that of Condillac. May not the former be called the philosophy of *reflection*, with as great propriety as the philosophy of *sensation* ?

² In considering Leibnitz as a partizan of the freedom of the will, Madame de Stael has also followed the views of many German writers, who make no distinction between Materialists and Necessitarians, imagining, that to assert the spirituality of the soul, is to assert its free-agency. On the inaccuracy of these conceptions it would be superfluous to enlarge, after what was formerly said in treating of the metaphysical opinions of Leibnitz.

In consequence of this misapprehension, Madame de Stael, and many other late writers on the Continent, have been led to employ, with a very exceptionable latitude, the word *Idealist*, to comprehend not only the advocates for the immateriality of the mind, but those also who maintain the Freedom of the Human Will. Between these two opinions, there is certainly no necessary connection ; Leibnitz, and many other German metaphysicians, denying the latter with no less confidence than that with which they assert the former.

In England, the word *Idealist* is most commonly restricted to such as (with Berkeley) reject the existence of a material world. Of late, its meaning has been sometimes extended (particularly since the publication of Reid) to all those who retain the theory of Descartes and Locke, concerning the immediate objects of our perceptions and thoughts, whether they admit or reject the consequences deduced from this theory by the Berkeleians. In the present state of the science, it would contribute much to the distinctness of our reasonings were it to be used in this last sense exclusively.

There is another word to which Madame de Stael and other writers on the German philosophy annex an idea peculiar to themselves ; I mean the word *experimental* or *empirical*. This epithet is often used by them to distinguish what they call the philosophy of Sensations, from that of Plato and of Leibnitz. It is accordingly generally, if not always, employed by them in an unfavourable sense. In this country, on the contrary, the experimental or inductive philosophy of the human mind denotes those speculations concerning mind, which, rejecting all hypothetical theories, rest solely on phenomena for which we have the evidence of consciousness. It is applied to the philosophy of Reid, and to all that is truly valuable in the metaphysical works of Descartes, Locke, Berkeley, and Hume.

Nor are the words *Experimental* and *Empirical* by any means synonymous in our language. The latter word is now almost exclusively appropriated to the practice of Medicine ; and when so understood always

Between these extremes reason continued to wander, till Kant undertook to trace the limits of the two empires; of the senses and of the soul; of the external and of the internal worlds. The force of meditation and of sagacity, with which he marked these limits, had not perhaps any example among his predecessors." (*Allemagne*, Vol. III. pp. 70, 72.)

The praise bestowed on this part of Kant's philosophy, by one of his own pupils, is not less warm than that of Madame de Staël. I quote the passage, as it enters into some historical details which she has omitted, and describes more explicitly than she has done one of the most important steps, which Kant is supposed by his disciples to have made beyond his predecessors. In reading it, some allowances must be made for the peculiar phraseology of the German school.

" Kant *discovered* that the intuitive faculty of man is a compound of very dissimilar ingredients; or, in other words, that it consists of parts very different in their nature, each of which performs functions peculiar to itself; namely, the *sensitive faculty*, and the *understanding*. Leibnitz, indeed, had likewise remarked the distinction subsisting between the sensitive faculty and the understanding; but he entirely overlooked the essential difference between their functions, and was of opinion that the faculties differed from one another only in degree. In the works of the English and French philosophers, we find this essential distinction between the sensitive and the intellectual faculties, and their combination towards producing one synthetical intuition scarcely mentioned. Locke only alludes to the accidental limitations of both faculties; but to inquire into the essential difference between them does not at all occur to him. This distinction, then, between the sensitive and the intellectual faculties, forms an essential feature in the philosophy of Kant, and is, indeed, the basis upon which most of his subsequent inquiries are established." (*Elements of the Cri. Phil.* by A. F. M. Willich, M. D. pp. 68, 69, 70.)

It is a circumstance not easily explicable, that, in the foregoing historical sketch, no mention is made of the name of Cudworth, author of the treatise on *Eternal and Immutable Morality*; a book which could scarcely fail to be known, before the period in question, to

implies a rash and unphilosophical use of Experience. " The appellation Empiric (says the late Dr John Gregory) is generally applied to one who, from observing the effects of a remedy in one case of a disease, applies it to all the various cases of that distemper." The same remark may be extended to the word *Empirique* in the French language, which is very nearly synonymous with *Charlatan*. In consequence of this abuse of terms, the epithet *experimental*, as well as *empirical*, is seldom applied by foreign writers to the philosophy of Locke, without being intended to convey a censure.

every German scholar, by the admirable Latin version of it published by Dr Mosheim.¹ In this treatise, Cudworth is at much pains to illustrate the Platonic doctrine concerning the difference between sensation and intellection; asserting that "some ideas of the mind proceed not from outward sensible objects, but arise from the inward activity of the mind itself;" that "even simple corporal things, passively perceived by sense, are known and understood only by the active power of the mind;" and that, besides *αἰσθηματα* and *φαντασματα*, there must be *νοηματα* or intelligible ideas, the source of which can be traced to the understanding alone.²

In the course of his speculations on these subjects, Cudworth has blended, with some very deep and valuable discussions, several opinions to which I cannot assent, and not a few

¹ The first edition of this translation was printed as early as 1732. From Buhle's *History of Modern Philosophy* (a work which did not fall into my hands till long after this section was written), I find that Cudworth's *Treatise of Immutable Morality* is now not only well known to the scholars of Germany, but that some of them have remarked the identity of the doctrines contained in it with those of Kant. "Meiners, dans son histoire générale de l'Ethique nie que le système morale de Cudworth soit identique avec celui de Platon, et prétend au contraire, ' que les principes considérés comme appartenans de la manière la plus spéciale à la morale de Kant, étaient enseignés il y a déjà plusieurs générations par l'école du philosophe Anglais." (*Hist. de la Phil. Moderne*, Tom. III. p. 577.) In opposition to this, Buhle states his own decided conviction—"qu'aucune des idées de Cudworth ne se rapproche de celles de Kant." (*Ibid.*) How far this conviction is well founded, the passage from Cudworth, quoted in the text, will enable my readers to judge for themselves.

That Cudworth has blended with his principles a vein of Platonic mysticism, which is not to be found in Kant, is undeniable; but it does not follow from this, that none of Kant's leading ideas are borrowed from the writings of Cudworth.

The assertion of Buhle, just mentioned, is the more surprising, as he himself acknowledges that—"La philosophie morale de Price présente en effet une analogie frappante avec celle de Kant;" and in another part of his work, he expresses himself thus on the same subject: "Le plus remarquable de tous les moralistes modernes de l'Angleterre est, sans contredit, Richard Price. . . . On remarque l'analogie la plus frappante entre ses idées sur les bases de la moralité, et celles que la philosophie critique a fait naître en Allemagne, quoique il ne soit cependant pas possible d'élever le plus petit doute sur l'entière originalité de ces dernières." (Tom. V. p. 302.) Is there any thing of importance in the system of Price, which is not borrowed from the *Treatise of Immutable Morality*? The distinguishing merit of this learned and most respectable writer is the good sense with which he has applied the doctrines of Cudworth to the sceptical theories of his own times.

In the sequel of Buhle's reflections on Cudworth's philosophy, we are told, that, according to him, "the will of God is only a simple blind power, acting mechanically or accidentally." ("Chez Cudworth la volonté même en Dieu, n'est qu'un simple pouvoir aveugle, agissant mécaniquement ou accidentellement.") If this were true, Cudworth ought to be ranked among the disciples, not of Plato, but of Spinoza.

² In this instance, a striking resemblance is observable between the language of Cudworth and that of Kant; both of them having followed the distinctions of the Socratic school, as explained in the *Theætetus* of Plato. They who are at all acquainted with Kant's *Critique*, will immediately recognize his phraseology in the passage quoted above.

propositions which I am unable to comprehend; but he seems to have advanced at least as far as Kant, in drawing the line between the provinces of the senses and of the understanding; and although not one of the most luminous of our English writers, he must be allowed to be far superior to the German metaphysician, both in point of perspicuity and of precision. A later writer, too, of our own country (Dr Price), a zealous follower both of Plato and of Cudworth, afterwards resumed the same argument, in a work which appeared long before the *Critique of Pure Reason*;¹ and urged it with much force against those modern metaphysicians, who consider the senses as the sources of all our knowledge. At a period somewhat earlier, many very interesting quotations of a similar import had been produced by the learned Mr Harris, from the later commentators of the Alexandrian school on the philosophy of Aristotle; and had been advantageously contrasted by him with the account given of the origin of our ideas, not only by Hobbes and Gassendi, but by many of the professed followers of Locke. If this part of the Kantian system, therefore, was new in Germany, it certainly could have no claim to the praise of originality, in the estimation of those at all acquainted with English literature.²

¹ See a review of the *Principal Questions and Difficulties relating to Morals*, by Richard Price, D. D. London, 1758.

² I have mentioned here only those works of a modern date, which may be reasonably presumed to be still in general circulation among the learned. But many very valuable illustrations of the Platonic distinction between the senses and the understanding may be collected from the English writers of the seventeenth century. Among these it is sufficient to mention at present the names of John Smith and Henry More of Cambridge, and of Joseph Glanville, the author of *Scep sis Scientifica*.

Cudworth's *Treatise of Eternal and Immutable Morality*, although it appears, from intrinsic evidence, to have been composed during the lifetime of Hobbes, was not published till 1731, when the author's manuscript came into the hands of his grandson, Francis Cudworth Masham, one of the Masters in Chancery. This work, therefore, could not have been known to Leibnitz, who died seventeen years before; a circumstance which may help to account for its having attracted so much less attention in Germany than his *Intellectual System*, which is repeatedly mentioned by Leibnitz in terms of the highest praise.

From an article in the *Edinburgh Review* (Vol. XXVII. p. 191). we learn, that large unpublished manuscripts of Dr Cudworth are deposited in the British Museum. It is much to be regretted (as the author of the article observes), that they should have been so long withheld from the public. "The press of the two Universities (he adds) would be properly employed in works, which a commercial publisher could not prudently undertake." May we not indulge a hope, that this suggestion will, sooner or later, have its due effect?

In the preface of Mosheim to his Latin version of the *Intellectual System*, there is a catalogue of Cudworth's unpublished remains, communicated to Mosheim by Dr Chandler then Bishop of Durham. Among these are two distinct works on the Controversy concerning Liberty and Necessity, of each of which works Mosheim has given us the general contents. One of the chapters is entitled, "Answer to the objection against Liberty. *μὴ δυνάμει ἀναγκασιῶς*." It is not probable that it contains any thing very new or important; but it would certainly be worth while to know the reply made by Cudworth to an objection which both Leibnitz and La Place have fixed upon as decisive of the point in dispute.

In order, however, to strike at the root of what the Germans call the *philosophy of sensation*, it was necessary to trace, with some degree of systematical detail, the origin of our most important *simple notions*; and for this purpose it seemed reasonable to begin with an analytical view of those faculties and powers, to the exercise of which the development of these notions is necessarily subsequent. It is thus that the simple notions of *time* and *motion* presuppose the exercise of the faculty of memory; and that the simple notions of *truth*, of *belief*, of *doubt*, and many others of the same kind, necessarily presuppose the exercise of the power of reasoning. I do not know, that, in this anatomy of the mind, much progress has hitherto been made by the German metaphysicians. A great deal certainly has been accomplished by the late Dr Reid; and something, perhaps, has been added to his labours by those of his successors.

According to Kant himself, his metaphysical doctrines first occurred to him while employed in the examination of Mr Hume's *Theory of Causation*. The train of thought by which he was led to them will be best stated in his own words; for it is in this way alone that I can hope to escape the charge of misrepresentation from his followers. Some of his details would perhaps have been more intelligible to my readers, had my plan allowed me to prefix to them a slight outline of Hume's philosophy. But this the general arrangement of my discourse rendered impossible; nor can any material inconvenience result in this instance, from the order which I have adopted, inasmuch as Hume's *Theory of Causation*, how new soever it may have appeared to Kant, is fundamentally the same with that of Malebranche, and of a variety of other old writers, both French and English.

¹ "Since the *Essays* (says Kant) of Locke and of Leibnitz, or rather since the origin of metaphysics, as far as their history extends, no circumstance has occurred, which might have been more decisive of the fate of this science than the attack made upon it by David Hume.² He proceeded upon a single but important idea in metaphysics, the connection of cause and effect, and the concomitant notions of power and action. He challenged *reason* to answer him what title she had to imagine, that any thing may be so constituted

¹ See the Preface of Kant to one of his Treatises, entitled *Prolegomena ad Metaphysicam quamque futuram quæ qua Scientia poterit prodire*. I have availed myself in the text of the English version of Dr Willich, from the German original, which I have carefully compared with the Latin version of Born. A few sentences, omitted by Willich, I have thought it worth while to quote, at the foot of the page, from the Latin translation. (*Elem. of Critical Philosophy*, by A. F. M. Willich, M. D. p. 10, *et seq.* London, 1798.)

² "*Humius*.—Qui quidem nullam huic cognitionis parti lucem adfudit, sed tamen excitavit scintillam, de quâ sane lumen potuisset accendi, si ea incidisset in fomitem, facile accipientem, cujusque scintillatio diligenter altâ fuerit et aucta."

as that, if it be given, something else is also thereby inferred; for the idea of cause denotes this. He proved, beyond contradiction, that it is impossible for reason to think of such a connection *à priori*, for it contains *necessity*; but it is not possible to perceive how, because something is, something else must necessarily be; nor how the idea of such a connection can be introduced *à priori*.

"Hence, he concluded, that reason entirely deceives herself with this idea, and that she erroneously considers it as her own child, when it is only the spurious offspring of imagination, impregnated by experience; a *subjective* necessity, arising from habit and the association of ideas being thus substituted for an *objective* one derived from perception. . . . However hasty and unwarrantable Hume's conclusion might appear, yet it was founded upon investigation; and this investigation well deserved, that some of the philosophers of his time should have united to solve, more happily if possible, the problem in the sense in which he delivered it: A complete reform of the science might have resulted from this solution. But it is a mortifying reflection, that his opponents, Reid, Beattie, Oswald, and, lastly, Priestley himself, totally misunderstood the *tendency* of his problem.¹ The question was not, whether the idea of cause be in itself proper and indispensable to the illustration of all natural knowledge, for this Hume had never doubted; but whether this idea be an object of thought through reasoning *à priori*; and whether, in this manner, it possesses internal evidence, independently of all experience; consequently, whether its utility be not limited to objects of sense alone. It was upon this point that Hume expected an explanation.²

"I freely own it was these suggestions of Hume's which first, many years ago, roused me from my dogmatical slumber, and gave to my inquiries quite a different direction in the field of speculative philosophy. I was far from being carried away by his conclusions, the fallacy of which chiefly arose from his not forming to himself an idea of the *whole of his problem*, but merely investigating a part of it, the solution of which was impossible without a comprehensive view of the whole. When we proceed on a well founded

¹ "Non potest sine certo quodam molestiæ sensu percipi, quantopere ejus adversarii, *Reidius, Oswaldus, Beattius*, et tandem *Priestleius*, a scopo quæstionis aberrarent, et propterea, quod ea semper acciperent pro concessis, quæ ipse in dubium vocaret, contra vero cum vehementia, et maximam partem cum ingenti immodestia ea probare gestirent, quæ illi nunquam in mentem venisset dubitare, *nulum* ejus ad emendationem ita negligenter, ut omnia in statu pristino manerent, quasi nihil quidquam factum videretur."

² Although nothing can be more unjust than these remarks, in the unqualified form in which they are stated by Kant, it must, I think, be acknowledged, that some grounds for them have been furnished by occasional passages which dropped from the pens of most of Mr Hume's Scottish opponents.

though not thoroughly digested thought, we may expect, by patient and continued reflection, to prosecute it farther than the acute genius had done to whom we are indebted for the first spark of this light. I first enquired, therefore, whether Hume's objection might not be a general one, and soon found, that the idea of cause and effect is far from being the only one, by which the understanding *à priori* thinks of the connection of things; but rather that the science of metaphysics is altogether founded upon these connections. I endeavoured to ascertain their number; and, having succeeded in this attempt, I proceeded to the examination of those general ideas, which, I was now convinced, are not, as Hume apprehended, derived from experience, but arise out of the pure understanding. This deduction, which seemed impossible to my acute predecessor, and which nobody besides him had ever conceived, although every one makes use of these ideas, without asking himself upon what their objective validity is founded; this deduction, I say, was the most difficult which could have been undertaken for the behoof of metaphysics; and what was still more embarrassing, metaphysics could not here offer me the smallest assistance, because that deduction ought first to establish the possibility of a system of metaphysics. As I had now succeeded in the explanation of Hume's problem, not merely in a particular instance, but with a view of the whole power of pure reason, I could advance with sure though tedious steps, to determine completely, and upon general principles, the compass of Pure Reason, both what is the sphere of its exertion, and what are its limits; which was all that was required for erecting a system of metaphysics upon a proper and solid foundation."

It is difficult to discover any thing in the foregoing passage on which Kant could found a claim to the slightest originality. A variety of English writers had, long before this work appeared, replied to Mr Hume, by observing that the understanding is itself a source of new ideas, and that it is from this source that our notions of cause and effect are derived. "Our certainty (says Dr Price) that every new event requires some cause, depends no more on experience than our certainty of any other the most obvious subject of intuition. In the idea of every *change*, is included that of its being an *effect*."¹ In the works of Dr Reid, many remarks of the same nature are to be found; but, instead of quoting any of these, I shall produce a passage from a much older author, whose mode of thinking and writing may perhaps be more agreeable to the taste of Kant's countrymen than the simplicity and precision aimed at by the disciples of Locke.

¹ *Review of the Principal Questions and Difficulties in Morals*, Chap. i. sect. 2. The first edition of this book was printed in 1758.

“ That there are some ideas of the mind (says Dr Cudworth), which were not stamped or imprinted upon it from the sensible objects without, and therefore must needs arise from the innate vigour and activity of the mind itself, is evident, in that there are, *First*, Ideas of such things as are neither affections of bodies, nor could be imprinted or conveyed by any local motions, nor can be pictured at all by the fancy in any sensible colours; such as are the ideas of wisdom, folly, prudence, imprudence, knowledge, ignorance, verity, falsity, virtue, vice, honesty, dishonesty, justice, injustice, volition, cogitation, nay of sense itself, which is a species of cogitation, and which is not perceptible by any sense; and many other such like notions as include something of cogitation in them, or refer to cogitative beings only; which ideas must needs spring from the active power and innate fecundity of the mind itself,¹ because the corporeal objects of sense can imprint no such things upon it. *Secondly*, In that there are many relative notions and ideas, attributed as well to corporeal as incorporeal things, that proceed wholly from the activity of the mind comparing one thing with another. Such as are CAUSE, EFFECT, means, end, order, proportion, similitude, dissimilitude, equality, inequality, aptitude, inaptitude, symmetry, asymmetry, whole and part, genus and species, and the like.”—*Immutable Morality*, pp. 148, 149.

It is not my business at present to inquire into the solidity of the doctrine here maintained. I would only wish to be informed what additions have been made by Kant to the reply given to Mr Hume by our English philosophers, and to direct the attention of my readers to the close resemblance between this part of Kant's system, and the argument which Cudworth opposed to Hobbes and Gassendi considerably more than a century ago.²

The following passage, from the writer last quoted, approaches so nearly to what Kant and other Germans have so often repeated of the distinction between *subjective* and *objective* truth, that I am tempted to connect it with the foregoing extract, as an additional proof that there are, at least, some metaphysical points, on which we need not search for instruction beyond our own island.

“ If there were no other perceptive power, or faculty, distinct from external sense, all our perceptions would be merely relative, seeming, and fantastical, and not reach to the absolute and certain truth of any thing; and every one would but, as Protagoras expounds,

¹ This is precisely the language of the German school: “ Les vérités nécessaires (says Leibnitz) sont le produit immédiat de l'activité intérieure.” (Tome I. p. 686 Tome II. pp. 42, 325. See Degerando, *Hist. Comp.* Tome II. p. 96.)

² In the attempt, indeed, which Kant has made to enumerate all the general ideas which are not derived from experience, but arise out of the pure understanding, he may well lay claim to the praise of originality. On this subject I shall only refer my readers to Note (DD) at the end of this *Dissertation*

"thinks his own private and relative thoughts truths," and all our cogitations being nothing but appearances, would be indifferently alike true phantasms, and one as another.

"But we have since also demonstrated, that there is another perceptive power in the soul superior to outward sense, and of a distinct nature from it, which is the power of knowing or understanding, that is, an active exertion from the mind itself. And, therefore, has this grand eminence above sense, that it is no idiopathy, not a mere private, relative, seeming, and fantastical thing, but the comprehension of that which absolutely is and is not."¹

After enlarging on the distinction between the sensitive faculty and the understanding, Kant proceeds to investigate certain essential conditions, without which neither the sensitive faculty nor its objects are conceivable. These conditions are *time* and *space*, which, in the language of Kant, are the *forms* of all phenomena. What his peculiar ideas are concerning their nature and attributes, my readers will find stated in his own words at the end of this Discourse, in an extract from one of his Latin publications.² From that extract, I cannot promise them much instruction; but it will at least enable them to judge for themselves of the peculiar character of Kant's metaphysical phraseology. In the mean time, it will be sufficient to mention here, for the sake of connection, that he denies the *objective* reality both of time and of space. The former he considers merely as a *subjective* condition, inseparably connected with the frame of the human mind, in consequence of which, it arranges sensible phenomena according to a certain law, in the order of succession. As to the latter, he asserts, that it is nothing *objective* or *real*, inasmuch as it is neither a substance, nor an accident, nor a relation; that its existence, therefore, is only *subjective* and *ideal*, depending on a fixed law, inseparable from the frame of the human mind. In consequence of this law, we are led to conceive all external things as placed in space; or (as Kant expresses it) we are led to consider *space as the fundamental form of every external sensation*.

In selecting Kant's speculations concerning *time* and *space*, as a specimen of his mode of writing, I was partly influenced by the consideration, that it furnishes, at the same time, a remarkable example of the concatenation which exists between the most remote and seemingly the most unconnected parts of his system. Who could suppose that his opinions on these subjects, the most abstract and the most controverted of any in the whole compass of metaphysics, bore on the great, practical question of the freedom of the Human Will? The combination appears, at first sight, so very extraordinary, that I have no

¹ *Immutable Morality*, p. 264, et seq.

² See Note (EE.)

doubt I shall gratify the curiosity of some of my readers by mentioning a few of the intermediate steps which, in this argument, lead from the premises to the conclusion.

That Kant conceived the free agency of man to be necessarily implied in his moral nature (or, at least, that he was anxious to offer no violence to the common language of the world on this point), appears from his own explicit declarations in various parts of his works. "Voluntas libera (says he in one instance) eadem est cum voluntate legibus moralibus obnoxia."¹

In all the accounts of Kant's philosophy, which have yet appeared from the pens of his admirers in this country, particular stress is laid on the ingenuity with which he has unloosed this knot, which had baffled the wisdom of all his predecessors. The following are the words of one of his own pupils, to whom we are indebted for the first, and, I think, not the least intelligible, view of his principles which has been published in our language.²

"Professor Kant is decidedly of opinion, that, although many strong and ingenious arguments have been brought forward in favour of the freedom of the will, they are yet very far from being decisive. Nor have they refuted the arguments urged by the Necessitarians, but by an appeal to ~~more~~ feeling, which, on such a question, is of no avail. For this purpose, it is indispensably necessary to call to our assistance the principles of Kant."

"In treating this subject (continues the same author), Kant begins with showing that the notion of a Free Will is not contradictory. In proof of this he observes, that, although every human action, as an event in time, must have a cause, and so on *ad infinitum*; yet it is certain, that the laws of cause and effect can have a place there only where time is, for the effect must be consequent on the cause. But neither time nor space are properties of things; they are only the general forms under which man is allowed to view himself and the world. It follows, therefore, that man is not in time nor in space, al-

¹ See Born's Latin Translation of Kant's Works, relating to the *Critical Philosophy*, Vol. II. p. 325, *et seq.* See also the Preface to Vol. III.

² *A General and Introductory View of Professor Kant's Principles concerning Man, the World, and the Deity, submitted to the consideration of the Learned*, by F. A. Nitsch, late Lecturer on the Latin Language and Mathematics in the Royal Fredericianum College at Königsberg, and Pupil of Professor Kant. London, 1796. pp. 172, 173.

This small performance is spoken of in terms highly favourable, by the other writers who have attempted to introduce Kant's philosophy into England. It is called by Dr Willich an excellent publication (*Elements of the Critical Philosophy*, p. 62); and is pronounced by the author of the elaborate articles on that subject in the *Encyclopædia Londonensis* to be a sterling work. "Though at present very little known, I may venture (says this writer) to predict, that, as time rolls on, and prejudices moulder away, this work, like the *Elements of Euclid*, will stand forth as a lasting monument of PURE TRUTH."—See Note (FF.)

though the forms of his intuitive ideas are time and space. But if man exist not in time and space, he is not influenced by the laws of time and space, among which those of cause and effect hold a distinguished rank; it is, therefore, no contradiction to conceive, that, in such an order of things, man may be free."¹

In this manner Kant establishes the *possibility* of man's freedom; and, farther than this, he does not conceive himself warranted to proceed on the principles of the critical philosophy. The first impression, certainly, which his argument produces on the mind is, that his own opinion was favourable to the scheme of necessity. For if the reasonings of the Necessitarians be admitted to be satisfactory, and if nothing can be opposed to them but the incomprehensible proposition, that man neither exists in space nor in time, the natural inference is, that this proposition was brought forward rather to save appearances, than as a serious objection to the universality of the conclusion.

Here, however, Kant calls to his aid the principles of what he calls *practical* reason. Deeply impressed with a conviction that morality is the chief concern of man, and that morality and the freedom of the human will must stand or fall together, he exerts his ingenuity to show, that the metaphysical proof already brought of the possibility of free-agency, joined to our own consciousness of a liberty of choice, affords evidence of the fact fully sufficient for the practical regulation of our conduct, although not amounting to what is represented as demonstration in the *Critique of Pure Reason*.²

¹ Nitsch, &c. pp. 174, 175.

² The account of this part of Kant's doctrine given by M. Buhle agrees in substance with that of Mr Nitsch: "Toute moralité des actions repose uniquement sur la disposition pratique, en tant qu'elle est déterminée par la loi morale seule. Si l'on considère cette disposition comme *phénomène* dans la conscience; c'est un événement naturel, elle obéit à la loi de la causalité, elle repose sur ce que l'homme a éprouvé auparavant dans le tems, et elle fait partie du caractère empirique de l'homme. Mais on peut aussi la considérer comme un acte de la liberté raisonnable: Alors elle n'est plus soumise à la loi de la causalité; elle est indépendante de la condition du tems, elle se rapporte à une cause intelligible, la liberté, et elle fait partie du caractère intelligible de l'homme. On ne peut, à la vérité, point acquérir la moindre connoissance des objets intelligibles; mais la liberté n'est pas moins un fait de la conscience. Donc les actions extérieures sont indifférentes pour la moralité de l'homme. La bonté morale de l'homme consiste uniquement dans sa volonté moralement bonne, et celle-ci consiste en ce que la volonté soit déterminée par la loi morale seule." (*Hist de la Philosophie Moderne*, par J. G. Buhle, Tom. VI. pp. 504, 505.)

Very nearly to the same purpose is the following statement by the ingenious author of the article *Leibnitz* in the *Biographie Universelle*: "Comment accorder le *fatum* et la liberté, l'imputation morale et la dépendance des êtres finies? Kant croit échapper à cet écueil en ne soumettant à la loi de causalité (au déterminisme de Leibnitz) que le monde phénoménique, et en affranchissant de ce principe l'ame comme *noumène* ou chose en soi, envisageant ainsi chaque action comme appartenant à un double série à la fois; à l'ordre physique où elle est enchaînée à ce qui précède et à ce qui suit par les liens communs de la nature, et à l'ordre morale, ou une dé-

It is impossible to combine together these two parts of the Kantian system, without being struck with the resemblance they bear to the deceitful sense of liberty to which Lord Kames had recourse (in the *first* edition of his *Essays on Morality and Natural Religion*), in order to reconcile our consciousness of free-agency with the conclusions of the Necessitarians. In both cases, the reader is left in a state of most uncomfortable scepticism, not confined to this particular question, but extending to every other subject which can give employment to the human faculties.¹

In some respects, the functions ascribed by Kant to his *practical* reason are analogous to those ascribed to common sense in the writings of Beattie and Oswald. But his view of the subject is, on the whole, infinitely more exceptionable than theirs, inasmuch as it sanctions the supposition, that the conclusions of *pure reason* are, in certain instances, at variance with *that* modification of reason which was meant by our Maker to be our guide in life; whereas the constant language of the other writers is, that all the different parts of our intellectual frame are in the most perfect harmony with each other. The motto which Beattie has prefixed to his book,

“ Nunquam aliud natura, aliud sapientia dicit,”

expresses, in a few significant words, the whole substance of his philosophy.

It is to the same *practical* modification of reason that Kant appeals in favour of the existence of the Deity, and of a future state of retribution, both of which articles of belief he thinks derive the whole of their evidence from the moral nature of man. His system, therefore, as far as I am able to comprehend it, tends rather to represent these as useful *credenda*, than as certain or even as probable truths. Indeed, the whole of his moral superstructure will be found to rest ultimately on no better basis than the metaphysical *conundrum*, that the human mind (considered as a *noumenon* and not as a *phenomenon*) neither exists in space nor in time.

termination produit un effet, sans que pour expliquer cette volition et son resultat, on soit renvoyé à un état antécédent.”

The author of the above passage is M. Staffer, to whom we are indebted for the article *Kant* in the same work. For Kant's own view of the subject consult his *Critique of Pure Reason*, *passim*, particularly p. 99, et seq. of Born's *Translation*, Vol. III.

¹ The idea of Kant (according to his own explicit avowal) was, that every thing, which conceives itself to be free, whether it be in reality so or not, is rendered by its own belief a moral and accountable agent. “ Jam equidem dico: quæque natura, quæ non potest, nisi *sub idea libertatis* agere, propter id ipsum, respectu practico, reipsa libera est; hoc est, ad eam valent cunctæ leges, cum libertate arctissime conjunctæ, perinde, ac

That it was Kant's original aim to establish a system of scepticism, I am far from being disposed to think.¹ The probability is, that he began with a serious wish to refute the doctrines of Hume; and that, in the progress of his inquiries, he met with obstacles of which he was not aware. It was to remove these obstacles that he had recourse to practical reason; an idea which has every appearance of being an *afterthought*, very remote from his views when he first undertook his work. This, too, would seem, from the following passage (which I translate from Degerando), to have been the opinion of one of Kant's ablest German commentators, M. Reinhold: "*Practical Reason* (as Reinhold ingeniously observes) is a wing which Kant has prudently added to his edifice, from a sense of the inadequacy of the original design to answer the intended purpose. It bears a manifest resemblance to what some philosophers call an appeal to *sentiment*, founding belief on the necessity of acting. Whatever contempt Kant may affect for popular systems of philosophy, this manner of considering the subject is not unlike the disposition of those who, feeling their inability to obtain, by the exercise of their reason, a direct conviction of their religious creed, cling to it nevertheless with a blind eagerness, as a support essential to their morals and their happiness." (*Hist Comparée*, Vol. II. pp. 243, 244.)

The extraordinary impression produced for a considerable time in Germany, by the *Critique of Pure Reason*, is very shrewdly, and I suspect justly, accounted for by the writer last quoted: "The system of Kant was well adapted to flatter the weaknesses of the hu-

voluntas ejus etiam per se ipsam, et in philosophia theoretica probata, libera declaretur." (Kantii Opera, Vol. II. p. 326.)

This is also the creed professed by the Abbé Galiani, a much more dangerous moralist than Kant, because he is always intelligible, and often extremely lively and amusing. "L'homme est donc libre, puisqu'il est intimement persuadé de l'être, et que cela vaut tout autant que la liberté. Voilà donc le mécanisme de l'univers expliqué clair comme de l'eau de roche." The same author farther remarks, "La persuasion de la liberté constitue l'essence de l'homme. On pourroit même définir l'homme un animal qui se croit libre, et ce seroit une définition complète." (*Correspondance ineditée de l'Abbé Galiani*, Tome I. pp. 339, 340. A Paris, 1818.)

¹ On the contrary, he declares explicitly (and I give him full credit for the sincerity of his words), that he considered his *Critique of Pure Reason* as the only effectual antidote against the opposite extremes of scepticism and of superstition, as well as against various heretical doctrines which at present infect the schools of philosophy. "Hæc igitur solâ (*Philosophia Criticâ*) et materialismi, et fatalismi, et Atheismi, et diffidentie profanæ, et fanaticismi, et superstitionis, quorum virus ad universos potest penetrare, tandemque etiam et idealismi, et scepticismi, qui magis scholis sunt pestiferi, radices ipsæ possunt præcidi." (Kant, *Præf. Posterior*, p. xxxv.)

man mind. Curiosity was excited, by seeing paths opened which had never been trodden before. The love of mystery found a secret charm in the obscurity which enveloped the doctrine. The long and troublesome period of initiation was calculated to rouse the ambition of bold and adventurous spirits. Their love of singularity was gratified by the new nomenclature; while their vanity exulted in the idea of being admitted into a privileged sect, exercising, and entitled to exercise, the supreme censorship in philosophy. Even men of the most ordinary parts, on finding themselves called to so high functions, lost sight of their real mediocrity, and conceived themselves transformed into geniuses destined to form a new era in the history of reason.

“ Another inevitable effect resulting from the universal change operated by Kant in his terms, in his classifications, in his methods, and in the enunciation of his problems. The intellectual powers of the greater part of the initiated were too much exhausted in the course of their long noviciate, to be qualified to judge soundly of the doctrine itself. They felt themselves, after so many windings, lost in a labyrinth, and were unable to dispense with the assistance of the guide who had conducted them so far. Others, after so great a sacrifice, wanted the courage to confess to the world, or to themselves, the disappointment they had met with. They attached themselves to the doctrine in proportion to the sacrifice they had made, and estimated its value by the labour it had cost them. As for more superficial thinkers, they drew an inference from the novelty of the form in favour of the novelty of the matter, and from the novelty of the matter in favour of its importance.

“ It is a great advantage for a sect to possess a distinguishing garb and livery. It was thus that the Peripatetics extended their empire so widely, and united their subjects in one common obedience. Kant had, over and above all this, the art of insisting, that his disciples should belong exclusively to himself. He explicitly announced, that he was not going to found a school of Ecclectics, but a school of his own; a school not only independent, but in some measure hostile to every other; that he could admit of no compromise with any sect whatever; that he was come to overturn every thing which existed in philosophy, and to erect a new edifice on these immense ruins. The more decided and arrogant the terms were in which he announced his design, the more likely was it to succeed; for the human mind submits more easily to an unlimited than to a partial faith, and yields itself up without reserve, rather than consent to cavil about restrictions and conditions even in favour of its own independence.”

With these causes of Kant's success another seems to have powerfully conspired; the indissoluble coherence and concatenation of all the different parts of his philosophy. “ It is on this concatenation (says M. Prevost) that the admiration of Kant's followers is

chiefly founded." *Grant only (they boast) the first principles of the Critical Philosophy, and you must grant the whole system.* The passage quoted on this occasion by M. Prevost is so forcibly expressed, that I cannot do it justice in an English version: "Ab hinc enim capitibus fluere necesse est omnem philosophiæ criticæ rationis puræ vim atque virtutem; namque in ea contextus rerum prorsus mirabilis est, ita ut extrema primis, media utrisque, omnia omnibus respondeant; si prima dederis danda sunt omnia."¹ No worse account could well have been given of a philosophical work on such a subject; nor could any of its characteristic features have been pointed out more symptomatic of its ephemeral reputation. Supposing the praise to be just, it represented the system, however fair and imposing in its first aspect, as vitally and mortally vulnerable (if at all vulnerable) in every point; and, accordingly, it was fast approaching to its dissolution before the death of its author. In Germany, at present, we are told, that a pure Kantian is scarcely to be found.² But there are many Semi-Kantians and Anti-Kantians as well as partisans of other schemes built out of the ruins of the Kantian philosophy.³ "In fine (says a late author), the *Critique of Pure Reason*, announced with pomp, received with fanaticism, disputed about with fury, after having accomplished the overthrow of the doctrines taught by Leibnitz and Wolff, could no longer support itself upon its own foundations, and has produced no permanent result, but divisions and enmities, and a general disgust at all systematical creeds."⁴ If this last effect has really resulted from it (of which some doubts may perhaps be entertained), it may be regarded as a favourable symptom of a sounder taste in matters of abstract science, than has ever yet prevailed in that country.⁵

¹ See some very valuable strictures on Kant, in the learned and elegant sketch of the present state of philosophy, subjoined to M. Prevost's French translation of Mr Smith's posthumous works. The Latin panegyric on the critical philosophy is quoted from a work with which I am unacquainted, *Fred. Gottlob Bornii de Scientia et Conjectura*.

² On this subject, see Degerando, Tom. II. p. 333.

³ See Degerando, and de Bonald.

⁴ The words in the original are, "Un dégoût générale de toute doctrine." But as the same word *doctrine* is, in a former part of the same sentence, applied to the systems of Leibnitz and of Wolff, I have little doubt, that, in substituting for *doctrine* the phrase *systematical creeds*, I have faithfully rendered the meaning of my author. (See *Recherches Philosophiques*, par M. de Bonald, Tom. I. pp. 43, 44.)

⁵ The passion of the Germans for systems is a striking feature in their literary taste, and is sufficient of itself to show, that they have not yet passed their novitiate in philosophy. "To all such (says Mr Mac-laurin) as have just notions of the Great Author of the universe, and of his admirable workmanship, all complete and finished systems must appear very suspicious." At the time when he wrote, such systems had not wholly lost their partisans in England; and the name of *System* continued to be a favourite title for a book even among writers of the highest reputation. Hence the *System of Moral Philosophy* by

To these details, I have only to add a remark of Degerando's, which I have found amply confirmed within the circle of my own experience. It might furnish matter for some useful reflections, but I shall leave my readers to draw their own conclusions from it. "Another remarkable circumstance is, that the defence of the Kantians turned, in general, not upon the *truth* of the disputed proposition, but upon the right interpretation of their master's meaning, and that their reply to all objections has constantly begun and ended with these words, *You have not understood us.*"

Among the various schools which have emanated from that of Kant, those of Fichte and Schelling seem to have attracted among their countrymen the greatest number of proselytes. Of neither am I able to speak from my own knowledge; nor can I annex any distinct idea to the accounts which are given of their opinions by others. Of Fichte's speculations about the philosophical import of the pronoun *I* (*Qu'est-ce que le moi?* as Degerando translates the question), I cannot make any thing. In some of his remarks, he approaches to the language of those Cartesians who, in the progress of their doubts, ended in absolute *egoism*: but the *ego*¹ of Fichte has a creative power. It creates *existence*, and it creates *science*; two things (by the way) which, according to him, are one and the same. Even *my own* existence, he tells me, commences only with the *reflex act*, by which I think of the pure and primitive *ego*. On this identity of the intelligent *ego* and the existing *ego* (which Fichte expresses by the formula *ego = ego*) all science ultimately rests. —But on this part of his metaphysics it would be idle to enlarge, as the author acknowledges, that it is not to be understood without the aid of a certain *transcendental sense*, the want of which is wholly irreparable; a singular admission enough (as Degerando observes), on the part of those critical philosophers who have treated with so much contempt the appeal to *Common Sense* in the writings of some of their predecessors.²

Hutcheson, and the *Complete System of Optics* by Smith, titles which, when compared with the subsequent progress of these two sciences, reflect some degree of ridicule upon their authors.

When this affectation of systematical method began, in consequence of the more enlarged views of philosophers, to give way to that aphoristical style so strongly recommended and so happily exemplified by Lord Bacon, we find some writers of the old school complaining of the innovation, in terms not unlike those in which the philosophy of the English has been censured by some German critics. "The best way (says Dr Watts) to learn any science, is to begin with a regular system. Now (he continues), we deal much in essays, and unreasonably despise systematical learning; whereas our fathers had a just value for regularity and systems." Had Dr Watts lived a few years later, I doubt not that his good sense would have led him to retract these hasty and inconsiderate decisions.

¹ In order to avoid the intolerable awkwardness of such a phrase as *the I*, I have substituted on this occasion the Latin pronoun for the English one.

² *Hist. Comparée, &c.* Tome II. pp. 300, 301. See also the article FICHTE in this *Supplement*.

the history of beings, Fichte (according to Schelling) three grand epochs; the first belongs to the empire of *chance*; the second is the reign of *nature*; the third *will be* the epoch of the existence of *God*. For God does not exist yet; he only manifests himself as preparing to exist. Nature tends to an apotheosis, and may be regarded as a sort of divinity in the germ.¹

The account given by Madame de Staël of this part of Fichte's system is considerably different: "He was heard to say, upon one occasion, that in his next lecture he 'was going to create God,'—an expression which, not without reason, gave general offence. His meaning was, that he intended to show how the idea of God arose and unfolded itself in the mind of man."² How this apology is well-founded, I am not competent to judge.

The system of Schelling is, in the opinion of Degerando, but an extension of that of Fichte; connecting with it a sort of Spinozism grafted on Idealism. In considering the primitive *ego* as the source of all reality as well as of all science, and in thus transporting the mind into an intellectual region, inaccessible to men possessed only of the ordinary number of senses, both agree; and to this vein of transcendental mysticism may probably be ascribed the extraordinary enthusiasm with which their doctrines appear to have been received by the German youth. Since the time when Degerando wrote, a new and very unexpected revolution is said to have taken place among Schelling's disciples; many of them, originally educated in the Protestant faith, having thrown themselves into the bosom of the Catholic church.³ "The union of the faithful of this school forms an invi-

¹ *Hist. Comparée, &c.* Tome II. p. 314. The doctrine here ascribed to Fichte by Degerando, although its unparalleled absurdity might well excite some doubts about the correctness of the historian, is not altogether a novelty in the history of philosophy. It is in point of fact nothing more than a return to those gross conceptions of the mind in the infancy of human reason, which Mr Smith has so well described in the following passage: "In the first ages of the world, the seeming incoherence of the appearances of nature so confounded mankind, that they despaired of discovering in her operations any regular system. . . . Their gods, though they were apprehended to interpose upon some particular occasions, were so far from being regarded as the creators of the world, that their origin was apprehended to be posterior to that of the world. The earth (according to Hesiod) was the first production of the chaos. The heavens arose out of the earth, and from both together, all the gods who afterwards inhabited them. Nor was this notion confined to the vulgar, and to those poets who seem to have recorded the vulgar theology. . . . The same notion of the spontaneous origin of the world was embraced (as Aristotle tells us) by the early Pythagoreans. . . Mind, and understanding, and consequently Deity, being the most perfect, were necessarily, according to them, the last productions of nature. For, in all other things, what was most perfect, they observed, always came last: as in plants and animals, it is not the seed that is most perfect, but the complete animal, with all its members in the one; and the complete plant, with all its branches, leaves, flowers, and fruits, in the other."—*Smith's Post. Essays on Philosophical Subjects*, pp. 106, 107.

² *De l'Allemagne.* Tome III. p. 107. Londres, 1815.

³ See a paper by M. G. Schweighauser in the *London Monthly Magazine* for 1804, p. 207.

sible church, which has adopted for its symbol and watch-word, the Virgin Mary; and hence rosaries are sometimes to be seen in the hands of those who reckon Spinoza among the greatest prophets." It is added, however, with respect to this invisible church, that "its members have embraced the Catholic religion, not as the *true* religion, but as the most *poetical*;" a thing not improbable among a people who have so strong a disposition to mingle together poetry and metaphysics in the same compositions.¹ But it is painful to contemplate these sad aberrations of human reason; nor would I have dwelt on them so long as I have done, had I not been anxious to convey to my readers a general, but I trust not unfaithful, idea of the style and spirit of a philosophy, which, within the short period of our recollection, rose, flourished, and fell; and which, in every stage of its history, furnished employment to the talents of some of the most learned and able of our contemporaries.²

The space which I have allotted to Kant has so far exceeded what I intended he should occupy, that I must pass over the names of many of his countrymen much more worthy of public attention. In the account given by Degerando of the opponents to the Kantian system, some remarks are quoted from different writers, which convey a very favourable idea of the works from which they are borrowed. Among these I would more particularly distinguish those ascribed to Jacobi and to Reinhold. In the *Memoirs*, too, of the Berlin Academy, where (as Degerando justly observes) the philosophy of Locke found an asylum, while banished from the rest of Germany, there is a considerable number of metaphysical articles of the highest merit.³ Nor must I omit to mention the con-

¹ "Aussi les Allemands [melent ils trop souvent la Métaphysique à la Poésie." (*Allemagne*, Vol. II. p. 133.)

² "Nothing (says Mr Hume) is more dangerous to reason than the flights of imagination, and nothing has been the occasion of more mistakes among philosophers. Men of bright fancies may, in this respect, be compared to those angels, whom the Scripture represents as covering their eyes with their wings." (*Treatise on Human Nature*, Vol. I. p. 464)

³ According to a French writer, who appears to have resided many years in Germany, and who has culled a short Essay on the *Elements of Philosophy* with many curious historical details concerning Kant and his successors,—both Fichte and Schelling owed much of their reputation to the uncommon eloquence displayed in their academical lectures: "Cette doctrine sortait de la bouche de Fichte, revêtue de ses ornemens qui démontrent la jeunesse, la beauté et la force au discours. On ne se lassait point en l'écouter."

Of Schelling he expresses himself thus: "Schelling, appelé à l'université de Wirzbourg, y attirait par sa réputation un concours nombreux d'auditeurs, qu'il enchainait à ses leçons par la richesse de sa diction et par l'étendue de ses connoissances. De là, il est venu à Munich, où je le revis en 1813. On dit qu'il a embrassé la religion Catholique." (*Essai sur les Elémens de la Philosophie*, par G. Gley, Principal au Collège d'Alençon. Paris, 1817. pp. 152, 153.)

⁴ In a volume of this collection (for the year 1797), which happens to be now lying before me, there

contributions to this science by the university of Göttingen; more especially on questions connected with the philosophy of language. I have great pleasure, also, in acknowledging the entertainment I have received, and the lights I have borrowed from the learned labours of Meiners and of Herder; but none of these are so closely connected with the history of metaphysics as to justify me in entering into particular details with respect to them. I am ashamed to say that, in Great Britain, the only one of these names which has been much talked of is that of Kant, a circumstance which, I trust, will apologize for the length to which the foregoing observations have extended.¹

The only other country of Europe from which any contributions to metaphysical philosophy could be reasonably looked for, during the eighteenth century, is Italy; and to this particular branch of science I do not know that any Italian of much celebrity has, in these later times, turned his attention. The metaphysical works of Cardinal Gerdil (a native of Savoy) are extolled by some French writers; but none of them have ever happened to fall in my way.² At a more recent period, Genovesi, a Neapolitan philosopher (best known as a political economist), has attracted a good deal of notice by some metaphysical publications. Their chief object is said to be to reconcile, as far as possible, the opinions of Leibnitz with those of Locke. "Pendant que Condillac donnait inutilement

are three profound and important *Memoirs on Probabilities*, by M. Prevost and M. l'Huillier. Neither of these authors, I am aware, is of German origin, but as the Academy of Berlin has had the merit to bring their papers before the public, I could not omit this opportunity of recommending them to the attention of my readers. To a very important observation made by MM. Prevost and l'Huillier, which has been the subject of some dispute, I am happy to avail myself of the same opportunity to express my unqualified assent. (See pp 15 and 31 of the memoirs belonging to the *Classe de Philosophie Speculative*.)

¹ See Note (GG)

² His two first publications, which were directed against the philosophy of Locke (if we may judge from their titles), are not likely, in the present times, to excite any curiosity. 1. *The Immateriality of the Soul Demonstrated against Mr Locke, on the same Principles on which this Philosopher has Demonstrated the Existence and the Immateriality of God*. Turin, 1747. 2. *Defence of the Opinion of Malebranche, on the Nature and Origin of our ideas, against the Examination of Mr Locke*. Turin, 1748. The only other works of Gerdil which I have seen referred to are, *A Dissertation on the Incompatibility of the Principles of Descartes with those of Spinoza*, and *A Refutation of some Principles maintained in the Emile of Rousseau*.

Of this last performance, Rousseau is reported to have said, "*Voula l'unique écrit public contre moi que j'aie trouvé digne l'être lu en entier.*" (*Nouveau Dict. Hist. article Gerdil*) In the same article, a reference is made to a public discourse of the celebrated M. Mairan, of the Academy of Sciences, in which he pronounces the following judgment on Gerdil's metaphysical powers: "*Gerdil porte avec lui dans tous ses discours un esprit géométrique, qui manque trop souvent aux géomètres mêmes.*"

³ Born 1712, died 1769.

des leçons à un Prince d'Italie, Genovesi en donnait avec plus de succès à ses élèves Napolitains : il combinait le mieux qu'il lui étoit possible les theories de Leibnitz pour lequel il eut toujours une prévention favorable, avec celle de Locke, qu'il accrédita le premier en Italie."¹ Various other works of greater or of less celebrity, from Italian authors, seems to announce a growing taste in that part of Europe for these abstract researches. The names of Francisco Soave, of Biagioli, and of Mariano Gigli, are advantageously mentioned by the countrymen; but none of their works, as far as I can learn, have yet reached Scotland. Indeed, with the single exception of Boscovich, I recollect no writer on the other side of the Alps, whose metaphysical speculations have been heard of in this island. This is the more to be regretted, as the specimens he has given, both of originality and soundness in some of his abstract discussions, convey a very favourable idea of the school in which he received his education. The authority to which he seems most inclined to lean is that of Leibnitz; but, on all important questions he exercises his own judgment, and often combats Leibnitz with equal freedom and success. Remarkable instances of this occur in his strictures on the principle of *the sufficient reason*, and in the limitations with which he has admitted the *law of continuity*.

The vigour, and, at the same time, the versatility of talents, displayed in the voluminous works of this extraordinary man, reflect the highest honour on the country which gave

¹ *Revue Encyclopédique, ou Analyse Raisonnée des Productions les plus Remarquables dans la Littérature, les Sciences, et les Arts.* I. Vol. 3me livraison, p. 515. Paris, Mars 1819. (The writer of the article quoted in the text is M. Sarpi, an Italian by birth, who, after having distinguished himself by various publications in his own country, has now (if I am not mistaken) fixed his residence at Paris. In his own philosophical opinions, he seems to be a follower of Condillac's school, otherwise he would scarcely have spoken so highly as he has done of the French Ideologists: "L'Idéologie qui, d'après sa denomination récente pourrait être considérée comme spécialement due aux Français, mais qui est aussi ancienne que la philosophie, puisqu'elle a pour objet la génération des idées et l'analyse des facultés qui concourent à leur formation, n'est pas étrangère aux Italiens, comme on pourrait le croire.")

Genovesi is considered, by an historian of high reputation, as the reformer of Italian philosophy. If the execution of his *Treatise on Logic* corresponds at all to the enlightened views with which the design seems to have been conceived, it cannot fail to be a work of much practical utility. "Ma chi può veramente dirsi il riformatore dell' Italiana filosofia, chi la fece tosto conoscere, e rispettare da' più dotti filosofi delle altre nazioni, chi seppe arricchire di nuovi pregi la logica, la metafisica, e la morale, fu il celebre Genovesi. Tutti che molti fossero stati i filosofi che cercarono con sottili riflessioni, e giusti precetti d'aiutare la mente a pensare ed a ragionare con esattezza e verità, e Bacone, Malebranche, Locke, Wolffio, e molt' altri sembrassero avere esaurito quanto v'era da scrivere su tale arte, seppe nondimeno il Genovesi trovare nuove osservazioni, e nuovi avvertimenti da proporre, e dare una logica più piena e compiuta, e più utile non solo allo studio della filosofia, e generalmente ad ogni studio scientifico, ma estendendo alla condotta morale, ed alla civile società." (*Dell' Origine, de Progressi, e dello Stato attuale d'Ogni Letteratura dell' Abate D. Giovanni Andres.* Tomo XV. pp. 260, 261, Venezia, 1800.)

him birth, and would almost tempt one to give credit to the theory which ascribes to the genial climates of the south a beneficial influence on the intellectual frame. Italy is certainly the only part of Europe where mathematicians and metaphysicians of the highest rank have produced such poetry as has proceeded from the pens of Boscovich and Stay. It is in this rare balance of imagination, and of the reasoning powers, that the perfection of the human intellect will be allowed to consist; and of this balance a far greater number of instances may be quoted from Italy (reckoning from Galileo¹ downwards), than in any other corner of the learned world.

The sciences of ethics, and of political economy, seem to be more suited to the taste of the modern Italians, than logic or metaphysics, properly so called. And in the two former branches of knowledge, they have certainly contributed much to the instruction and improvement of the eighteenth century. But on these subjects we are not yet prepared to enter.

In the New World, the state of society and of manners has not hitherto been so favourable to abstract sciences as to pursuits which come home directly to the business of human life. There is, however, one metaphysician of whom America has to boast, who, in logical acuteness and subtilty, does not yield to any disputant bred in the universities of Europe. I need not say, that I allude to Jonathan Edwards. But, at the time when he wrote, the state of America was more favourable than it now is, or can for a long period be expected to be, to such inquiries as those which engaged his attention; inquiries (by the way) to which his thoughts were evidently turned, less by the impulse of speculative curiosity, than by his anxiety to defend the theological system in which he had been educated, and to which he was most conscientiously and zealously attached. The effect of this anxiety in sharpening his faculties, and in keeping his polemical vigilance constantly *on the alert*, may be traced in every step of his argument.²

¹ See a most interesting account of Galileo's taste for poetry and polite literature in Ginguené, *Histoire Littéraire d'Italie*. Tome V. pp. 331, et seq. à Paris, 1812.

² While this Dissertation was in the press, I received a new American publication, entitled, "*Transactions of the Historical and Literary Committee of the American Philosophical Society, held at Philadelphia, for Promoting Useful Knowledge*," Vol. I. (Philadelphia, 1819.) From an advertisement prefixed to this volume, it appears that, at a meeting of this learned body in 1815, it was resolved, "That a new committee be added to those already established, to be denominated the Committee of History, Moral Science, and General Literature." It was with great pleasure I observed, that one of the first objects to which the committee has directed its attention is to investigate and ascertain, as much as possible, the structure and grammatical forms of the languages of the aboriginal nations of America. The Report of the corresponding secretary (M Duponceau), dated January 1819, with respect to the progress then made in this investigation, is highly curious and interesting, and displays not only enlarged and philosophical views, but an intimate acquaintance with the philo-

In the mean time, a new and unexpected mine of intellectual wealth has been opened to the learned of Europe, in those regions of the East, which, although in all probability the cradle of civilization and science, were, till very lately, better known in the annals of commerce than of philosophy. The metaphysical and ethical remains of the Indian sages are, in a peculiar degree, interesting and instructive; inasmuch as they seem to have furnished the germs of the chief systems taught in the Grecian schools. The favourite theories, however, of the Hindoos will, all of them, be found, more or less, tinctured with those ascetic habits of abstract and mystical meditation which seem to have been, in all ages, congenial to their constitutional temperament. Of such habits, an Idealism, approaching to that of Berkeley and Malebranche, is as natural an offspring, as Materialism is of the gay and dissipated manners, which, in great and luxurious capitals, are constantly inviting the thoughts abroad.

To these remains of ancient science in the East, the attention of Europe was first called by Bernier, a most intelligent and authentic traveller, of whom I formerly took notice as a favourite pupil of Gassendi. But it is chiefly by our own countrymen that the field which he opened has been subsequently explored; and of their meritorious labours in the prosecution of this task, during the reign of our late Sovereign, it is scarcely possible to form too high an estimate.

Much more, however, may be yet expected, if such a prodigy as Sir William Jones should again appear, uniting, in as miraculous a degree, the gift of tongues with the spirit of philosophy. The structure of the Sanscrit, in itself, independently of the treasures locked up in it, affords one of the most puzzling subjects of inquiry that was ever presented to human ingenuity. The affinities and filiations of different tongues, as evinced

logical researches of Adelung, Vater, Humboldt, and other German scholars. All this evinces an enlightened curiosity, and an extent of literary information, which could scarcely have been expected in these rising states for many years to come.

The rapid progress which the Americans have lately made in the art of writing has been remarked by various critics, and it is certainly a very important fact in the history of their literature. Their state papers were, indeed, always distinguished by a strain of animated and vigorous eloquence; but as most of them were composed on the spur of the occasion, their authors had little time to bestow on the niceties, or even upon the purity of diction. An attention to these is the slow offspring of learned leisure, and of the diligent study of the best models. This I presume was Gray's meaning, when he said, that "good writing not only required great parts, but the very best of those parts;" a maxim which, if true, would point out the state of the public taste with respect to style, as the surest test among any people of the general improvement which their intellectual powers have received; and which, when applied to our Trans-atlantic brethren, would justify sanguine expectations of the attainments of the rising generation.

* Note of Mason on a Letter of Gray's to Dr Wharton, on the death of Dr Middleton.

in their corresponding roots and other coincidences, are abundantly curious, but incomparably more easy in the explanation, than the systematical analogy which is said to exist between the Sanscrit and the Greek (and also between the Sanscrit and the Latin, which is considered as the most ancient dialect of the Greek), in the conjugations and flexions of their verbs, and in many other particulars of their mechanism; an analogy which is represented as so complete, that, in the versions which have been made from the one language into the other, "Sanskrit," we are told, "answers to Greek, as face to face in a glass."¹ That the Sanscrit did not grow up to the perfection which it now exhibits, from popular and casual modes of speech, the unexampled regularity of its forms seems also to demonstrate, and yet, should this supposition be rejected, to what other hypothesis shall we have recourse, which does not involve equal, if not greater improbabilities? The problem is well worthy of the attention of philosophical grammarians; and the solution of it, whatever it may be, can scarcely fail to throw some new lights on the history of the human race, as well as on that of the human mind.

SECTION VIII.

Metaphysical Philosophy of Scotland.

It now only remains for me to take a slight survey of the rise and progress of the Metaphysical Philosophy of Scotland; and if, in treating of this, I should be somewhat more minute than in the former parts of this Historical Sketch, I flatter myself that allowances will be made for my anxiety to supply some chasms in the literary history of my country, which could not be so easily, nor perhaps so authentically, filled up by a younger hand.

The Metaphysical Philosophy of Scotland, and, indeed, the literary taste in general, which so remarkably distinguished this country during the last century, may be dated from the lectures of Dr Francis Hutcheson, in the University of Glasgow. Strong indications of the same speculative spirit may be traced in earlier writers;² but it was from this period

¹ Letter from the Reverend David Brown, Provost of the College of Fort-William, about the *Sanskrit Edition of the Gospels*, (dated Calcutta, September 1806, and published in some of the *Literary Journals* of the day.)

² See Note (HH.)

that Scotland, after a long slumber, began again to attract general notice in the republic of letters.¹

The writings of Dr Hutcheson, however, are more closely connected with the history of Ethical than of Metaphysical Science; and I shall, accordingly, delay any remarks which I have to offer upon them till I enter upon that part of my subject. There are, indeed, some very original and important metaphysical hints scattered over his works; but it is chiefly as an ethical writer that he is known to the world, and that he is entitled to a place among the philosophers of the eighteenth century.²

¹ An Italian writer of some note, in a work published in 1763, assigns the same date to the revival of letters in Scotland. “Fra i tanti, e sì chiari Scrittori che fiorirono nella Gran Bretagna a’ tempi della Regina Anna, non se ne conta pur uno, che sia uscito di Scozia Francesco Hutcheson venuto in Iscozia, a professarvi la Filosofia, e gli studii di umanità, nella Università di Glasgow, v’insinuò per tutto il paese colle istruzioni a viva voce, e con egregie opere date alle stampe, un vivo genio per gli studii filosofici, e letterarii, e sparse qui fecondissimi semi, d’onde vediamo nascere sì felici frutti, e sì copiose.” (*Discorso sopra le Vicende della Letteratura, del Sig. Carlo Denina*, p. 224, Glasgow edit. 1763.)

I was somewhat surprised to meet with the foregoing observations in the work of a foreigner, but, wherever he acquired his information, it evinces, in those from whom it was derived, a more intimate acquaintance with the traditionary history of letters in this country than has fallen to the share of most of our own authors who have treated of that subject. I have heard it conjectured, that the materials of his section on Scottish literature had been communicated to him by Mr. Hume.

Another foreign writer, much better qualified than Denina to appreciate the merits of Hutcheson, has expressed himself on this subject with his usual precision. “L’école Ecossaise a en quelque sorte pour fondateur Hutcheson maître et prédécesseur de Smith. C’est ce philosophe qui lui a imprimé son caractère, et qui a commencé à lui donner de l’éclat.” In a note upon this passage the author observes,—“C’est en ce seul sens qu’on peut donner un chef à une école de philosophie qui, comme on le verra, professe d’ailleurs la plus parfaite indépendance de l’autorité.”—(See the excellent reflections upon the posthumous works of Adam Smith, annexed by M. Prevost to his translation of that work.)

Dr Hutcheson’s first course of lectures at Glasgow was given in 1730. He was a native of Ireland, and is accordingly called by Denina “un dotto Irlandese;” but he was of Scotch extraction (his father or grandfather having been a younger son of a respectable family in Ayrshire), and he was sent over when very young to receive his education in Scotland.

² One of the chief objects of Hutcheson’s writings was to oppose the licentious system of Mandeville; a system which was the natural offspring of some of Locke’s reasonings against the existence of innate practical principles.

As a moralist, Hutcheson was a warm admirer of the ancients, and seems to have been particularly smitten with that favourite doctrine of the Socratic school which identifies the *good* with the *beautiful*. Hence he was led to follow much too closely the example of Shaftesbury, in considering moral distinctions as founded more on sentiment than on reason, and to speak vaguely of virtue as a sort of *noble enthusiasm*; but he was led, at the same time, to connect with his ethical speculations some collateral inquiries concerning Beauty and Harmony, in which he pursued, with considerable success, the path recently struck out by Addison in his *Essays on the Pleasures of the Imagination*. These inquiries of Hutcheson, together with his *Thoughts*

Among the contemporaries of Dr Hutcheson, there was one Scottish metaphysician (Andrew Baxter, author of the *Inquiry into the Nature of the Human Soul*), whose name it would be improper to pass over without some notice, after the splendid eulogy bestowed on his work by Warburton. "He who would see the justest and precisest notions of God and the soul may read this book, one of the most finished of the kind, in my humble opinion, that the present times, greatly advanced in true philosophy, have produced."¹

To this unqualified praise, I must confess, I do not think Baxter's *Inquiry* altogether entitled, although I readily acknowledge that it displays considerable ingenuity, as well as learning. Some of the remarks on Berkeley's argument against the existence of matter are acute and just, and, at the time when they were published, had the merit of novelty.

One of his distinguishing doctrines is, that the Deity is the *immediate* agent in producing the phenomena of the *Material World*; but that, in the *Moral World*, the case is different,—a doctrine which, whatever may be thought of it in other respects, is undoubtedly a great improvement on that of Malebranche, which, by representing God as the only agent in the universe, was not less inconsistent than the scheme of Spinoza with the moral nature of Man. "The Deity (says Baxter) is not only at the head of Nature, but in every part of it. A chain of material causes betwixt the Deity and the effect produced, and much more a series of them, is such a supposition as would conceal the Deity from the knowledge of mortals for ever. We might search for matter above matter, till we were lost in a labyrinth out of which no philosopher ever yet found his way.—This way of bringing in second causes is borrowed from the government of the moral world, where free agents act a part; but it is very improperly applied to the material universe, where matter and motion only (or mechanism, as it is called) comes in competition with the Deity."²

Notwithstanding, however, these and other merits, Baxter has contributed so little to the advancement of that philosophy which has since been cultivated in Scotland, that I am afraid the very slight notice I have now taken of him may be considered as an unseasonable digression. The great object of his studies plainly was, to strengthen the old argument for the soul's immateriality, by the new lights furnished by Newton's discoveries.

on *Laughter*, although they may not be very highly prized for their depth, bear everywhere the marks of an enlarged and cultivated mind, and, whatever may have been their effects elsewhere, certainly contributed powerfully, in our Northern seats of learning, to introduce a taste for more liberal and elegant pursuits than could have been expected so soon to succeed to the intolerance, bigotry, and barbarism of the preceding century.

¹ See Warburton's *Divine Legation of Moses demonstrated*, p. 395 of the first edition.

² Appendix to the first part of the *Inquiry into the Nature of the Human Soul*, pp. 109, 110.

To the intellectual and moral phenomena of Man, and to the laws by which they are regulated, he seems to have paid but little attention.¹

While Dr Hutcheson's reputation as an author, and still more as an eloquent teacher, was at its zenith in Scotland, Mr Hume began his literary career, by the publication of his *Treatise of Human Nature*. It appeared in 1739, but seems at that time to have attracted little or no attention from the public. According to the author himself, "never literary attempt was more unfortunate. It fell dead-born from the press, without reaching such distinction as even to excite a murmur among the zealots." It forms, however, a very important link in this Historical Sketch, as it has contributed, either directly or indirectly, more than any other single work, to the subsequent progress of the Philosophy of the Human Mind. In order to adapt his principles better to the public taste, the author afterwards threw them into the more popular form of Essays; but it is in the original work that philosophical readers will always study his system, and it is there alone that the relations and bearings of its different parts, as well as its connection with the speculations of his immediate predecessors, can be distinctly traced. It is there, too, that his metaphysical talents appear, in my opinion, to the greatest advantage; nor am I certain that he has anywhere else displayed more skill or a sounder taste in point of composition.²

¹ Baxter was born at Old Aberdeen, in 1686 or 1687, and died at Whittingham, in East Lothian, in 1750. I have not been able to discover the date of the first edition of his *Inquiry into the Nature of the Human Soul*, but the second edition appeared in 1737, two years before the publication of Mr Hume's *Treatise of Human Nature*.

² A gentleman, who lived in habits of great intimacy with Dr Reid towards the close of his life, and on whose accuracy I can fully depend, remembers to have heard him say repeatedly, that "Mr Hume, in his *Essays*, appeared to have forgotten his *Metaphysics*." Nor will this supposition be thought improbable, if, in addition to the subtle and fugitive nature of the subjects canvassed in the *Treatise of Human Nature*, it be considered that long before the publication of his *Essays*, Mr Hume had abandoned all his metaphysical researches. In proof of this, I shall quote a passage from a letter of his to Sir Gilbert Elliot, which, though without a date, seems from its contents to have been written about 1750 or 1751. The passage is interesting on another account, as it serves to show how much Mr Hume undervalued the utility of mathematical learning, and consequently how little he was aware of its importance, as an organ of physical discovery, and as the foundation of some of the most necessary arts of civilized life. "I am sorry that our correspondence should lead us into these abstract speculations. I have thought, and read, and composed very little on such questions of late. Morals, politics, and literature, have employed all my time; but still the other topics I must think more curious, important, entertaining, and useful, than any geometry that is deeper than Euclid."

I have said that it is in Mr Hume's earliest work that his metaphysical talents appear, in my opinion, to the greatest advantage. From the following advertisement, however, prefixed in the latest editions of his works to the second volume of his *Essays and Treatises*, Mr Hume himself would appear to have thought differently. "Most of the principles and reasonings contained in this volume were published in a work in three

The great object of Mr. Hume's *Treatise of Human Nature* will be best explained in his own words.

" 'Tis evident that all the sciences have a relation, greater or less, to human nature, and that, however wide any of them may seem to run from it, they still return back by one passage or another. Even Mathematics, Natural Philosophy, and Natural Religion, are in some measure dependent on the science of Man, since they lie under the cognizance of men, and are judged of by their powers and faculties. If, therefore, the sciences of Mathematics, Natural Philosophy, and Natural Religion, have such a dependence on the knowledge of man, what may be expected in the other sciences, whose connection with human nature is more close and intimate? The sole end of logic is to explain the principles and operations of our reasoning faculty, and the nature of our ideas: Morals and criticism regard our tastes and sentiments, and politics consider men as united in society, and dependent on each other. Here, then, is the only expedient from

volumes, called *A Treatise of Human Nature*; a work which the author had projected before he left College, and which he wrote and published not long after. But not finding it successful, he was sensible of his error in going to the press too early, and he cast the whole anew in the following pieces, where some negligences in his former reasoning, and some in the expression, are, he hopes, corrected. Yet several writers, who have honoured the author's philosophy with answers, have taken care to direct all their batteries against that juvenile work, which the author never acknowledged, and have affected to triumph in any advantage which they imagined they had obtained over it; a practice very contrary to all rules of candour and fair dealing, and a strong instance of those polemical artifices which a bigoted zeal thinks itself authorised to employ. Henceforth, the author desires, that the following pieces may alone be regarded as containing his philosophical sentiments and principles."

After this declaration, it certainly would be highly uncandid to impute to Mr Hume any philosophical sentiments or principles not to be found in his *Philosophical Essays*, as well as in his *Treatise*. But where is the unfairness of replying to any plausible arguments in the latter work, even although Mr Hume may have omitted them in his subsequent publications; more especially where these arguments supply any useful lights for illustrating his more popular compositions? The *Treatise of Human Nature* will certainly be remembered as long as any of Mr Hume's philosophical writings; nor is any person qualified either to approve or to reject his doctrines, who has not studied them in the systematical form in which they were originally cast. That Mr Hume's remonstrance may be just with respect to some of his adversaries, I believe to be true; but it is surely expressed in a tone more querulous and peevish than is justified by the occasion.

I shall take this opportunity of preserving another judgment of Mr Hume's (still more fully stated) on the merits of this juvenile work. I copy it from a private letter written by himself to Sir Gilbert Elliot, soon after the publication of his *Philosophical Essays*.

" I believe the *Philosophical Essays* contain every thing of consequence relating to the Understanding, which you would meet with in the *Treatise*; and I give you my advice against reading the latter. By shortening and simplifying the questions I really render them more complete. *Addo dum minuo*. The philosophical principles are the same in both; but I was carried away by the heat of youth and invention to publish too precipitately. So vast an undertaking, planned before I was one and twenty, and composed before twenty-five, must necessarily be very defective. I have repented my haste a hundred and a hundred times."

which we can hope for success in our philosophical researches, to leave the tedious lingering method which we have hitherto followed, and, instead of taking now and then a castle or village on the frontier, to march up directly to the capital or centre of these sciences, to human nature itself; which, being once masters of, we may everywhere else hope for an easy victory. From this station we may extend our conquests over all those sciences which more intimately concern human life, and may afterwards proceed at leisure to discover more fully those which are the objects of pure curiosity. There is no question of importance whose decision is not comprised in the Science of Man, and there is none which can be decided with any certainty before we become acquainted with that science. In pretending, therefore, to explain the principles of Human Nature, we, in effect, propose a complete system of the sciences, built on a foundation almost entirely new, and the only one upon which they can stand with any security.

“ And, as the science of man is the only solid foundation for the other sciences, so the only solid foundation we can give to this science itself must be laid on experience and observation. ’Tis no astonishing reflection to consider, that the application of experimental philosophy to moral subjects should come after that to natural, at the distance of above a whole century; since we find, in fact, that there was about the same interval betwixt the origin of these sciences; and that, reckoning from Thales to Socrates, the space of time is nearly equal to that betwixt my Lord Bacon and some late philosophers in England,¹ who have begun to put the science of man on a new footing, and have engaged the attention, and excited the curiosity of the public.”

I am far from thinking, that the execution of Mr Hume’s work corresponded with the magnificent design sketched out in these observations; nor does it appear to me that he had formed to himself a very correct idea of the manner in which the experimental mode of reasoning ought to be applied to moral subjects. He had, however, very great merit in separating entirely his speculations concerning the philosophy of the mind from all physiological hypotheses about the nature of the union between soul and body; and although, from some of his casual expressions, it may be suspected that he conceived our intellectual operations to result from bodily organization,² he had yet much too large a share

¹ “ Mr Locke, Lord Shaftesbury, Dr Mandeville, Mr Hutcheson, Dr Butler,” &c.

² The only expression in his works I can recollect at present, that can give any reasonable countenance to such a suspicion, occurs in his *Posthumous Dialogues*, where he speaks of “ that little agitation of the brain which we call thought.” (2d Edition, pp. 60, 61.) But no fair inference can be drawn from this, as the expression is put into the mouth of Philo the Sceptic; whereas the author intimates that Cleanthes speaks his own sentiments.

of good sense and sagacity to suppose, that, by studying the latter, it is possible for human ingenuity to throw any light upon the former. His works, accordingly, are perfectly free from those gratuitous and wild conjectures, which a few years afterwards were given to the world with so much confidence by Hartley and Bonnet. And in this respect his example has been of infinite use to his successors in this northern part of the island. Many absurd theories have, indeed, at different times been produced by our countrymen; but I know of no part of Europe where such systems as those of Hartley and Bonnet have been so uniformly treated with the contempt they deserve as in Scotland.¹

Nor was it in this respect alone, that Mr Hume's juvenile speculations contributed to forward the progress of our national literature. Among the many very exceptionable doctrines involved in them, there are various discussions, equally refined and solid, in which he has happily exemplified the application of metaphysical analysis to questions connected with taste, with the philosophy of jurisprudence, and with the theory of government. Of these discussions some afterwards appeared in a more popular form in his philosophical and literary essays, and still retain a place in the latest editions of his works. but others, not less curious, have been suppressed by the author, probably from an idea, that they were too abstruse to interest the curiosity of ordinary readers. In some of these practical applications of metaphysical principles, we may perceive the germs of several inquiries which have since been successfully prosecuted by Mr Hume's countrymen; and, among others, of those which gave birth to Lord Kames's *Historical Law Tracts*, and to his *Elements of Criticism*.

The publication of Mr Hume's *Treatise* was attended with another important effect in Scotland. He had cultivated the art of writing with much greater success than any of his predecessors, and had formed his taste on the best models of English composition. The influence of his example appears to have been great and general; and was in no instance more remarkable than in the style of his principal antagonists, all of whom, in studying his system, have caught, in no inconsiderable degree, the purity, polish, and precision of his diction. Nobody, I believe, will deny, that Locke himself, considered as an English writer, is far surpassed, not only by Hume, but by Reid, Campbell, Gerard, and Beattie; and of this fact it will not be easy to find a more satisfactory explanation, than in the critical eye with which they were led to canvass a work, equally distinguished by the depth of its reasonings, and by the attractive form in which they are exhibited.

¹ In no part of Mr Hume's metaphysical writings is there the slightest reference to either of these systems, although he survived the date of their publication little less than thirty years.

„The fundamental principles from which Mr Hume sets out, differ more in words than in substance from those of his immediate predecessors. According to him, all the objects of our knowledge are divided into two classes, *impressions* and *ideas*: the former, comprehending our *sensations*, properly so called, and also our *perceptions* of sensible qualities (two things betwixt which Mr Hume's system does not lead him to make any distinction); the latter, the objects of our thoughts when we *remember* or *imagine*, or in general exercise any of our intellectual powers on things which are past, absent, or future. These ideas he considers as *copies* of our *impressions*, and the words which denote them as the only *signs* entitled to the attention of a philosopher; every word professing to denote an idea, of which the corresponding impressions cannot be pointed out, being *ipso facto* unmeaning and illusory. The obvious result of these principles is, that what Mr Hume calls *impressions* furnish, either immediately or mediately, the whole materials about which our thoughts can be employed; a conclusion coinciding exactly with the account of the origin of our ideas borrowed by Gassendi from the ancient Epicureans.

With this fundamental principle of the Gassendists, Mr Hume combined the logical method recommended by their great antagonists the Cartesians, and (what seemed still more remote from his Epicurean starting ground) a strong leaning to the idealism of Malebranche and of Berkeley. Like Descartes, he began with doubting of every thing, but he was too quick sighted to be satisfied, like Descartes, with the solutions given by that philosopher of his doubts. On the contrary, he exposes the futility not only of the solutions proposed by Descartes himself, but of those suggested by Locke and others among his successors; ending at last where Descartes began, in considering no one proposition as more certain, or even as more probable than another. That the proofs alleged by Descartes of the existence of the material world are quite inconclusive, had been already remarked by many. Nay, it had been shown by Berkeley and others, that if the principles be admitted on which Descartes, in common with all philosophers, from Aristotle downwards, proceeded, the existence of the material world is impossible. A few bold thinkers, distinguished by the name of Egoists, had gone still farther than this, and had pushed their scepticism to such a length, as to doubt of every thing but their own existence. According to these, the proposition *cogito, ergo sum*, is the only truth which can be regarded as absolutely certain. It was reserved for Mr Hume to call in question even this proposition, and to admit only the existence of *impressions* and *ideas*. To dispute against the existence of these he conceived to be impossible, inasmuch as they are the immediate subjects of consciousness. But to admit the existence of the thinking and percipient *I*, was to admit the existence of that imaginary substance called *Mind*, which (according to him)

is no more an object of human knowledge, than the imaginary and exploded substance called *Matter*.

From what has been already said, it may be seen, that we are not to look in Hume's *Treatise* for any regular or connected system. It is neither a scheme of Materialism, nor a scheme of Spiritualism; for his reasonings strike equally at the root of both these theories. His aim is to establish a universal scepticism, and to produce in the reader a complete distrust in his own faculties. For this purpose he avails himself of the data assumed by the most opposite sects, shifting his ground skilfully from one position to another, as best suits the scope of his present argument. With the single exception of Bayle, he has carried this sceptical mode of reasoning farther than any other modern philosopher. Cicero, who himself belonged nominally to the same school, seems to have thought, that the controversial habits imposed on the Academical sect by their profession of universal doubt, required a greater versatility of talent and fertility of invention, than were necessary for defending any particular system of tenets;¹ and it is not improbable, that Mr Hume, in the pride of youthful genius, was misled by this specious but very fallacious idea. On the other hand, Bayle has the candour to acknowledge, that nothing is so easy as to dispute after the manner of the sceptics;² and to this proposition every man of reflection will find himself more and more disposed to assent, as he advances in life. It is experience alone that can convince us, how much more difficult it is to make any real progress in the search after truth, than to acquire a talent for plausible disputation.³

¹ "Nam si singulas disciplinas percipere magnum est, quanto majus omnes? quod facere iis necesse est quibus propositum est, veri reperiendi causa, et contra omnes philosophos et pro omnibus dicere.—Cujus rei tantumque difficilis facultatem consecutum esse me non profiteor: Secutum esse præ me fero."—*Cicero de Nat. Deor.* l. i. v.

² See the passage quoted from Bayle, in p. 86 of this *Dissertation*.

³ In the very interesting account, given by Dr Holland, of Velara, a modern Greek physician, whom he met with at Larissa in Thessaly, a few slight particulars are mentioned, which let us completely into the character of that ingenious person. "It appeared (says Dr Holland) that Velara had thought much on the various topics of Metaphysics and Morals, and his conversation on these topics bore the same tone of satirical scepticism which was apparent as the general feature of his opinions. We spoke of the questions of Materialism and Necessity, on both of which he declared an affirmative opinion."—(Holland's *Travels in the Ionian Isles*, &c. p. 275.) "I passed this evening with Velara at his own house, and sat with him till a late hour. During part of the time our conversation turned upon metaphysical topics, and chiefly on the old Pyrrhonic doctrine of the non-existence of Matter. Velara, as usual, took the sceptical side of the argument, in which he showed much ingenuity and great knowledge of the more eminent controversialists on this and other collateral subjects." (*Ibid.* p. 370.) We see here a lively picture of a character daily to be met with in more polished and learned societies, disputing not for truth but for victory; in the first conversation professing himself a *Materia*'ist; and in the second denying the existence of Matter; on both occasions, tak-

That this spirit of sceptical argument has been carried to a most pernicious excess in modern Europe, as well as among the ancient Academics, will, I presume, be now very generally allowed; but in the form in which it appears in Mr Hume's *Treatise*, its mischievous tendency has been more than compensated by the importance of those results for which it has prepared the way. The principles which he assumes were sanctioned in common by Gassendi, by Descartes, and by Locke; and from these, in most instances, he reasons with great logical accuracy and force. The conclusions to which he is thus led are often so extravagant and dangerous, that he ought to have regarded them as a proof of the unsoundness of his data; but if he had not the merit of drawing this inference himself, he at least forced it so irresistibly on the observation of his successors, as to be entitled to share with them in the honour of their discoveries. Perhaps, indeed, it may be questioned if the errors which he adopted from his predecessors would not have kept their ground till this day, had not his sagacity displayed so clearly the consequences which they necessarily involve. It is in this sense that we must understand a compliment paid to him by the ablest of his adversaries, when he says, that "Mr Hume's premises often do more than atone for his conclusions."¹

The bias of Mr Hume's mind to scepticism seems to have been much encouraged, and the success of his sceptical theories in the same proportion promoted, by the recent attempts of Descartes and his followers to demonstrate Self-evident Truths,—attempts which Mr Hume clearly perceived to involve, in every instance, that sort of paralogism which logicians call *reasoning in a circle*. The weakness of these pretended demonstrations is triumphantly exposed in the *Treatise of Human Nature*; and it is not very wonderful that the author, in the first enthusiasm of his victory over his immediate predecessors, should have fancied that the inconclusiveness of the proofs argued some unsound-

ing up that ground where he was most likely to provoke opposition. If any inference is to be drawn from the conversation of such an individual, with respect to his real creed, it is in favour of those opinions which he controverts. These opinions, at least, we may confidently conclude to be agreeable to the general belief of the country where he lives.

¹ Mr Hume himself (to whom Dr Reid's *Inquiry* was communicated previous to its publication by their common friend Dr Blair) seems not to have been dissatisfied with this apology for some of his speculations. "I shall only say (he observes in a letter addressed to the author), that if you have been able to clear up these abstruse and important subjects, instead of being mortified, I shall be so vain as to pretend to a share of the praise, and shall think that my errors, by having at least some coherence, had led you to make a more strict review of my principles, which were the common ones, and to perceive their futility."—(For the whole of Mr Hume's letter, see *Biographical Memoirs* of Smith, Robertson, and Reid, by the author of this Dissertation, p. 417.)

ness in the propositions which they were employed to support. It would, indeed, have done still greater honour to his sagacity if he had ascribed this to its true cause—the possibility of confirming, by a process of reasoning, the *fundamental laws of Human belief*; but (as Bacon remarks) it does not often happen to those who labour in the field of science, that the same person who sows the seed should reap the harvest.

From that strong sceptical bias which led this most acute reasoner, on many important questions, to shift his controversial ground according to the humour of the moment, one favourable consequence has resulted—that we are indebted to him for the most powerful antidotes we possess against some of the most poisonous errors of modern philosophy. I have already made a similar remark in speaking of the elaborate refutation of Spinozism by Bayle; but the argument stated by Hume, in his *Essay on the Idea of Necessary Connection* (though brought forward by the author with a very different view), forms a still more valuable accession to metaphysical science, as it lays the axe to the very root from which Spinozism springs. The cardinal principle on which the whole of that system turns is, that all events, physical and moral, are *necessarily* linked together as causes and effects; from which principle all the most alarming conclusions adopted by Spinoza follow as unavoidable and manifest corollaries. But, if it be true, as Mr Hume contends, and as most philosophers now admit, that physical causes and effects are known to us merely as *antecedents* and *consequents*; still more, if it be true that the word *necessity*, as employed in this discussion, is altogether unmeaning and insignificant, the whole system of Spinoza is nothing better than a rope of sand, and the very proposition which it professes to demonstrate is incomprehensible by our faculties. Mr Hume's doctrine, in the unqualified form in which he states it, may lead to other consequences not less dangerous; but, if he had not the good fortune to conduct metaphysicians to the truth, he may at least be allowed the merit of having shut up for ever one of the most frequented and fatal paths which led them astray.

In what I have now said, I have supposed my readers to possess that general acquaintance with Mr Hume's *Theory of Causation* which all well-educated persons may be presumed to have acquired. But the close connection of this part of his work with some of the historical details which are immediately to follow, makes it necessary for me, before I proceed farther, to recapitulate a little more particularly some of his most important conclusions.

It was, as far as I know, first shown in a satisfactory manner by Mr Hume, that “every demonstration which has been produced for the necessity of a cause to every new existence is fallacious and sophistical.”¹ In illustration of this assertion, he examines three different

¹ *Treatise of Human Nature*, Vol. I. p. 144.—Although Mr Hume, however, succeeded better than any

arguments which have been alleged as proofs of the proposition in question; the first by Mr. Hobbes; the second by Dr. Clarke; and the third by Mr. Locke. And I think it will now be readily acknowledged by every competent judge, that his objections to all these pretended demonstrations are conclusive and unanswerable.

When Mr. Hume, however, attempts to show that the proposition in question is not *intuitively* certain, his argument appears to me to amount to nothing more than a logical quibble. Of this one would almost imagine that he was not insensible himself, from the short and slight manner in which he hurries over the discussion. "All certainty (he observes) arises from the comparison of ideas, and from the discovery of such relations as are unalterable, so long as the ideas continue the same. These relations are *resemblance, proportions in quantity and number, degrees of any quality, and contrariety*; none of which are implied in this proposition, *whatever has a beginning has also a cause of existence*. That proposition, therefore, is not intuitively certain. At least, any one who would assert it to be intuitively certain, must deny these to be the only infallible relations, and must find some other relation of that kind to be implied in it, which it will be then time enough to examine."

Upon this passage, it is sufficient for me to observe, that the whole force of the reasoning hinges on two assumptions, which are not only gratuitous, but false. *1st*, That all certainty arises from the comparison of ideas. *2dly*, That *all* the unalterable relations among our ideas are comprehended in his own arbitrary enumeration; *Resemblance, proportions in quantity and numbers, degrees of any quality, and contrariety*. When the correctness of these two premises shall be fully established, it will be time enough (to borrow Mr. Hume's own words) to examine the justness of his conclusion.

From this last reasoning, however, of Mr. Hume, it may be suspected, that he was aware of the vulnerable point against which his adversaries were most likely to direct their attacks. From the weakness, too, of the entrenchments which he has here thrown up for his own security, he seems to have been sensible, that it was not capable of

of his predecessors, in calling the attention of philosophers to this discussion, his opinion on the subject does not possess the merit, in point of originality, which was supposed to belong to it either by himself or by his antagonists. See the passages which I have quoted in proof of this, in the first volume of the *Philosophy of the Human Mind*, p. 542, *et seq.* fourth edit. and also in the second volume of the same work, p. 556, *et seq.* second edit. Among these, I request the attention of my readers more particularly to a passage from a book entitled *The Procedure, Extent, and Limits of the Human Understanding*, published two years before the *Treatise of Human Nature*, and commonly ascribed to Dr. Browne, Bishop of Cork. The coincidence is truly wonderful, as it can scarcely, by any possibility, be supposed that this book was ever heard of by Mr. Hume.

a long or vigorous resistance. In the mean time, he betrays no want of confidence in his original position; but repeating his assertion, that "we derive the opinion of the necessity of a cause to every new production, neither from demonstration nor from intuition?" he boldly concludes, that "this opinion must necessarily arise from observation and experience." (Vol. I. p. 147.) Or, as he elsewhere expresses himself; "All our reasonings concerning causes and effects are derived from nothing but custom; and, consequently, belief is more properly an act of the *sensitive* than of the *cogitative* part of our natures." (*Ibid.* p. 321.)

The distinction here alluded to between the *sensitive* and the *cogitative* parts of our nature (it may be proper to remind my readers) makes a great figure in the works of Cudworth and of Kant. By the former it was avowedly borrowed from the philosophy of Plato. To the latter, it is not improbable, that it may have been suggested by this passage in Hume. Without disputing its justness or its importance, I may be permitted to express my doubts of the propriety of stating, so strongly as has frequently been done, the one of these parts of our nature in contrast with the other. Would it not be more philosophical, as well as more pleasing, to contemplate the beautiful harmony between them; and the gradual steps by which the mind is trained by the intimations of the former, for the deliberate conclusions of the latter? If, for example, our conviction of the permanence of the laws of nature be not founded on any process of reasoning (a proposition which Mr Hume seems to have established with demonstrative evidence), but be either the result of an instinctive principle of belief, or of the association of ideas, operating at a period when the light of reason has not yet dawned, what can be more delightful than to find this suggestion of our *sensitive frame*,¹ verified by every step which our reason afterwards makes in the study of physical science; and confirmed with mathematical accuracy by the never-failing accordance of the phenomena of the heavens with the previous calculations of astronomers! Does not this afford a satisfaction to the mind, similar to what it experiences, when we consider the adaptation of the instinct of suction, and of the organs of respiration, to the physical properties of the atmosphere? So far from encouraging scepticism, such a view of human nature seems peculiarly calculated to silence every doubt about the veracity of our faculties.²

¹ Upon either of these suppositions, Mr Hume would, with equal propriety, have referred our anticipation of the future event to the *sensitive part of our nature*; and, in point of fact, the one supposition would have answered his purpose as well as the other.

² It is but justice to Mr Hume to remark, that, in his later publications, he has himself suggested this very idea as the best solution he could give of his own doubts. The following passage, which appears to me to

It is not my business at present to inquire into the soundness of Mr. Hume's doctrines on this subject. The rashness of some of them has, in my opinion, been sufficiently shown by more than one of his antagonists. I wish only to remark the important step which he made, in exposing the futility of the reasonings by which Hobbes, Clarke, and Locke, had attempted to demonstrate the metaphysical axiom, that "every thing which begins to exist must have a cause;" and the essential service which he rendered to true philosophy, by thus pointing out indirectly to his successors, the only solid ground on which that principle is to be defended. It is to this argument of Hume's, according to Kant's own acknowledgment, that we owe the *Critique of Pure Reason*; and to this we are also indebted for the far more luminous refutations of scepticism by Mr. Hume's own countrymen.

In the course of Mr Hume's very refined discussions on this subject, he is led to apply

be eminently philosophical and beautiful, I beg leave to recommend to the particular attention of Kant's disciples:

"Here, then, is a kind of pre-established harmony between the course of nature and the succession of our ideas; and though the powers and forces by which the former is governed be wholly unknown to us, yet our thoughts and conceptions have still, we find, gone on in the same train with the other works of nature. Custom is that principle by which this correspondence has been effected; so necessary to the subsistence of our species, and the regulation of our conduct in every circumstance and occurrence of human life. Had not the presence of an object instantly excited the idea of those objects commonly conjoined with it, all our knowledge must have been limited to the narrow sphere of our memory and senses; and we should never have been able to adjust means to ends, or employ our natural powers, either to the producing of good, or avoiding of evil. Those who delight in the discovery and contemplation of *final causes* have here ample subject to employ their wonder and admiration.

"I shall add, for a further confirmation of the foregoing theory, that, as this operation of the mind, by which we infer like effects from like causes, and *vice versa*, is so essential to the subsistence of all human creatures, it is not probable that it could be trusted to the fallacious deductions of our reason, which is slow in its operations, appears not in any degree, during the first years of infancy; and at best is, in every age and period of human life, extremely liable to error and mistake. It is more conformable to the ORDINARY WISDOM OF NATURE to secure so necessary an act of the mind by some instinct or mechanical tendency which may be infallible in its operations, may discover itself at the first appearance of life and thought, and may be independent of all the laboured deductions of the understanding. As nature has taught us the use of our limbs, without giving us the knowledge of the muscles and nerves by which they are actuated, so has she implanted in us an instinct which carries forward the thoughts in a correspondent course to that which she has established among external objects; though we are ignorant of those powers and forces on which this regular course and succession of objects totally depends." (See, in the last editions of Mr Hume's *Philosophical Essays*, published during his own lifetime, the two sections entitled *Sceptical Doubts concerning the Operations of the Understanding*; and *Sceptical Solution of these Doubts*. The title of the latter of these sections has, not altogether without reason, incurred the ridicule of Dr Beattie, who translates it, *Doubtful Solution of Doubtful Doubts*. But the essay contains much sound and important matter, and throws a strong light on some of the chief difficulties which Mr Hume himself had started. Sufficient justice has not been done to it by his antagonists.)

them to one of the most important principles of the mind,—our belief of the continuance of the laws of nature; or, in other words, our belief that the future course of nature will resemble the past. And here, too (as I already hinted), it is very generally admitted, that he has succeeded completely in overturning all the theories which profess to account for this belief by resolving it into a process of reasoning.¹ The only difference which seems to remain among philosophers is, whether it can be explained, as Mr Hume imagined, by means of the association of ideas; or, whether it must be considered as an original and fundamental law of the human understanding—a question, undoubtedly abundantly curious, as a problem connected with the *Theory of the Mind*; but to which more practical importance has sometimes been attached than I conceive to be necessary.²

¹ The incidental reference made, by way of illustration, in the following passage, to our *instinctive conviction* of the permanency of the laws of Nature, encourages me to hope, that, among candid and intelligent inquirers, it is now received as an acknowledged fact in the 'Theory of the Human Mind.

“The anxiety men have in all ages shown to obtain a fixed standard of value, and that remarkable agreement of nations, dissimilar in all other customs, in the use of one medium, on account of its superior fitness for that purpose, is itself a convincing proof how essential it is to our social interests. The notion of its permanency, although it be conventional and arbitrary, and liable, in reality, to many causes of variation, yet had gained so firm a hold on the minds of men, as to resemble, in its effects on their conduct, that *instinctive conviction of the permanency of the laws of nature which is the foundation of all our reasoning*.” (*A Letter to the Right Hon. R. Peel, M. P. for the University of Oxford*, by one of his Constituents. Second edition, p. 23.)

² The difference between the two opinions amounts to nothing more than this, whether our expectation of the continuance of the laws of nature results from a principle coëval with the first exercise of the senses; or whether it arises gradually from the accommodation of the order of our thoughts to the established order of physical events. “Nature (as Mr Hume himself observes) may certainly produce whatever can arise from habit; nay, habit is nothing but one of the principles of nature, and derives all its force from that origin.” (*Treatise of Human Nature*, Vol. I. p. 313.) Whatever ideas, therefore, and whatever principles we are unavoidably led to acquire by the circumstances in which we are placed, and by the exercise of those faculties which are essential to our preservation, are to be considered as parts of human nature no less than those which are implanted in the mind at its first formation. Are not the acquired perceptions of sight and of hearing as much parts of human nature as the original perceptions of external objects which we obtain by the use of the hand?

The passage quoted from Mr Hume, in Note 2, p. 180, if attentively considered, will be found, when combined with these remarks, to throw a strong and pleasing light on his latest views with respect to this part of his philosophy.

In denying that our expectation of the continuance of the laws of nature is founded on reasoning, as well as in asserting our ignorance of any necessary connections among physical events, Mr Hume had been completely anticipated by some of his predecessors. (See the references mentioned in the Note, p. 178.) I do not, however, think that, before his time, philosophers were at all aware of the alarming consequences which, on a superficial view, seem to follow from this part of his system. Indeed, these consequences would never have been apprehended, had it not been supposed to form an essential link in his argument against the commonly received notion of Causation.

That Mr Hume himself conceived his refutation of the theories which profess to assign *a reason* for our faith in the permanence of the laws of nature, to be closely connected with his sceptical conclusions concerning *causation*, is quite evident from the general strain of his argument; and it is, therefore, not surprising that this refutation should have been looked on with a suspicious eye by his antagonists. Dr Reid was, I believe, the first of these who had the sagacity to perceive, not only that it is strictly and inconvertibly logical, but that it may be safely admitted, without any injury to the doctrines which it was brought forward to subvert.

Another of Mr Hume's attacks on these doctrines was still bolder and more direct. In conducting it he took his vantage ground from his own account of the origin of our ideas. In this way he was led to expunge from his Philosophical Vocabulary every word of which the meaning cannot be explained by reference to the *impression* from which the corresponding *idea* was originally copied. Nor was he startled in the application of this rule, by the consideration, that it would force him to condemn, as insignificant, many words which are to be found in all languages, and some of which express what are commonly regarded as the most important objects of human knowledge. Of this number are the words *cause* and *effect*; at least, in the sense in which they are commonly understood both by the vulgar and by philosophers. "One event (*says he*) *follows another*, but we never observe any tie between them. They seem *conjoined*, but never *connected*. And as we can have no idea of any thing which never appeared to our outward sense or inward sentiment, the necessary conclusion seems to be, that we have no idea of connection or power at all; and that these words are absolutely without any meaning, when employed either in philosophical reasonings or common life." (Hume's *Essays*, Vol. II. p. 79. Ed. of Lond. 1784.)

When this doctrine was first proposed by Mr Hume, he appears to have been very strongly impressed with its repugnance to the common apprehensions of mankind. "I am sensible (he observes) that of all the paradoxes which I have had, or shall hereafter have occasion to advance in the course of this treatise, the present one is the most violent." (*Treatise of Human Nature*, Vol. I. p. 291.) It was probably owing to this impression that he did not fully unfold in that work all the consequences which, in his subsequent publications, he deduced from the same paradox; nor did he even apply it to invalidate the argument which infers the existence of an *intelligent* cause from the order of the universe. There cannot, however, be a doubt that he was aware, at this period of his life, of the conclusions to which it unavoidably leads, and which are indeed too obvious to escape the notice of a far less acute inquirer.

In a private letter of Mr Hume's to one of his most intimate friends,¹ some light is thrown on the circumstances which first led his mind into this train of sceptical speculation. As his narrative has every appearance of the most perfect truth and candour, and contains several passages which I doubt not will be very generally interesting to my readers, I shall give it a place, together with some extracts from the correspondence to which it gave rise, in the Notes at the end of this *Dissertation*. Every thing connected with the origin and composition of a work which has had so powerful an influence on the direction which metaphysical pursuits have since taken, both in Scotland² and in Germany, will be allowed to form an important article of philosophical history; and this history I need not offer any apology for choosing to communicate to the public rather in Mr Hume's words than in my own.³

¹ Sir Gilbert Elliot, Bart. grandfather of the present Earl of Minto. The originals of the letters to which I refer are in Lord Minto's possession.

² A foreign writer, of great name (M. Frederick Schlegel), seems to think that the influence of Mr Hume's *Treatise of Human Nature* on the Philosophy of England has been still more extensive than I had conceived it to be. His opinion on this point I transcribe as a sort of literary curiosity.

"Since the time of Hume, nothing more has been attempted in England, than to erect all sorts of bulwarks against the practical influence of his destructive scepticism; and to maintain, by various substitutes and aids, the pile of moral principle uncorrupted and entire. Not only with Adam Smith, but with all their late philosophers, national welfare is the ruling and central-principle of thought;—a principle excellent and praiseworthy in its due situation, but quite unfilled for being the centre and oracle of all knowledge and science." From the connection in which this last sentence stands with the context, would not one imagine that the writer conceived the *Wealth of Nations* to be a new moral or metaphysical system, devised by Mr Smith, for the purpose of counteracting Mr Hume's scepticism?

I have read this translation of Mr Schlegel's lectures with much curiosity and interest, and flatter myself that we shall soon have English versions of the works of Kant, and of other German authors, from the pens of their English disciples. Little more, I am fully persuaded, is necessary, in this country, to bring down the philosophy of Germany to its proper level.

In treating of literary and historical subjects, Mr Schlegel seems to be more in his element, than when he ventures to pronounce on philosophical questions. But even in cases of the former description, some of his dashing judgments on English writers can be accounted for only by haste, caprice, or prejudice. "The English themselves (we are told) are now pretty well convinced, that Robertson is a careless, superficial, and blundering historian: although they study his works, and are right in doing so, as models of pure composition, extremely deserving of attention during the present declining state of English style. With all the abundance of his Italian elegance, what is the overloaded and affected Roscoe when compared with Gibbon? Coxe, although master of a good and classical style, resembles Robertson in no respect so much as in the superficialness of his researches; and the statesman Fox has nothing in common with Hume but the bigotry of his party zeal." Such criticisms may perhaps be applauded by a German auditory, but in this country they can injure the reputation of none but their author.

³ See Note (II.)

From the reply to this letter by Mr Hume's very ingenious and accomplished correspondent, we learn that he had drawn from Mr Hume's metaphysical discussions the only sound and philosophical inference: that the lameness of the proofs offered by Descartes and his successors, of some fundamental truths universally acknowledged by mankind, proceeded, not from any defect in the evidence of these truths, but, on the contrary, from their being *self-evident*, and consequently unsusceptible of demonstration. We learn, farther, that the same conclusion had been adopted, at this early period, by another of Mr Hume's friends, Mr Henry Home, who, under the name of Lord Kames, was afterwards so well known in the learned world. Those who are acquainted with the subsequent publications of this distinguished and most respectable author will immediately recognize, in the account here given of the impression left on his mind by Mr Hume's scepticism, the rudiments of a peculiar logic, which runs more or less through all his later works; and which, it must be acknowledged, he has, in various instances, carried to an unphilosophical extreme.¹

The light in which Mr Hume's scepticism appears from these extracts to have struck his friends, Sir Gilbert Elliot and Lord Kames, was very nearly the same with that in which it was afterwards viewed by Reid, Oswald, and Beattie, all of whom have manifestly aimed, with greater or less precision, at the same logical doctrine which I have just alluded to. This, too, was the very ground on which Father Buffier had (even before the publication of the *Treatise of Human Nature*) made his stand against similar theories, built by his predecessors on the Cartesian principles. The coincidence between his train of thinking, and that into which our Scottish metaphysicians soon after fell is so very remarkable, that it has been considered by many as amounting to a proof that the plan of their works was, in some measure, suggested by his; but it is infinitely more probable, that the argument which runs, in common, through the speculations of all of them, was the natural result of the state of metaphysical science when they engaged in their philosophical inquiries.²

¹ I allude particularly to the unnecessary multiplication, in his philosophical arguments, of internal senses and of instinctive principles.

² Voltaire, in his catalogue of the illustrious writers who adorned the reign of Louis XIV. is one of the very few French authors who have spoken of Buffier with due respect: "Il y a dans ses traités de métaphysique des morceaux que Locke n'aurait pas désavoués, et c'est le seul jésuite qui ait mis une philosophie raisonnable dans ses ouvrages." Another French philosopher, too, of a very different school, and certainly not disposed to overrate the talents of Buffier, has, in a work published as lately as 1805, candidly acknowledged the lights which he might have derived from the labours of his predecessor, if he had been acquainted with them at

authority of the scripture, the deference which it commands to the church, the tradition of the church, &c. &c. The comparison of these controversial writings begat an idea in some, that it was neither by reasoning nor authority we learn our religion, but by sentiment; and this was certainly a very convenient way, and what a philosopher would be very well pleased to comply with, if he could distinguish sentiment from education. But, to all appearance, the sentiment of Stockholm, Geneva, Rome, ancient and modern, Athens, and Memphis, have the same characters; and no thinking man can implicitly assent to any of them, but from the general principle, that, as the truth on these subjects is beyond human capacity, and that, as for one's own case, he must adopt some tenets, there is more satisfaction and convenience in holding to the catechism we have been first taught. Now, this I have nothing to say against. I would only observe, that such a conduct is founded on the most universal and determined scepticism. For more curiosity and research give a direct opposite turn from the same principles."

On this careless effusion of Mr Hume's pen, it would be unpardonable to offer any critical strictures. It cannot, however, be considered as improper to hint, that there is a wide and essential difference between those articles of faith, which formed the subjects of dispute between Nicole and Claude, and those *laws of belief*, of which it is the great object of the *Treatise of Human Nature* to undermine the authority. The reply of Mr Hume, therefore, is evasive, and although strongly marked with the writer's ingenuity, does not bear upon the point in question.

As to the distinction alleged by Mr Hume between the *criteria* of truth in natural philosophy and in metaphysics, I trust it will now be pretty generally granted, that, however well founded it may be when confined to the metaphysics of the schoolmen, it will by no means hold when extended to the inductive philosophy of the human mind. In this last science, no less than in natural philosophy, Mr Hume's logical maxim may be laid down as a fundamental principle, that "whatever conclusion is contrary to matter of fact must be wrong, and there must some error lie somewhere in the argument, whether we be able to show it or not."

It is a remarkable circumstance in the history of Mr Hume's literary life, and a proof of the sincerity with which he was then engaged in the search of truth, that, previous to the publication of his *Treatise of Human Nature*, he discovered a strong anxiety to submit it to the examination of the celebrated Dr Butler, author of the *Analogy of Religion, Natural and Revealed, to the Constitution and Course of Nature*. For this purpose he applied to Mr Henry Home, between whom and Dr Butler some friendly letters appear to have passed before this period. "Your thoughts and mine (says Mr Hume to his

correspondent) agree with respect to Dr Butler, and I would be glad to be introduced to him. I am at present castrating my work, that is, cutting off its nobler parts; that is, endeavouring it shall give as little offence as possible, before which I could not preterp^d to put it into the doctor's hands."¹ In another letter, he acknowledges Mr Home's kindness in recommending him to Dr Butler's notice. "I shall not trouble you with any formal compliments or thanks, which would be but an ill return for the kindness you have done me in writing in my behalf, to one you are so little acquainted with as Dr Butler; and, I am afraid, stretching the truth in favour of a friend. I have called on the doctor, with a design of delivering your letter, but find he is at present in the country. I am a little anxious to have the doctor's opinion. My own I dare not trust to; both because it concerns myself, and because it is so variable, that I know not how to fix it. Sometimes it elevates me above the clouds; at other times it depresses me with doubts and fears; so that, whatever be my success, I cannot be entirely disappointed."

Whether Mr Hume ever enjoyed the satisfaction of a personal interview with Dr Butler, I have not heard. From a letter of his to Mr Home, dated London, 1729, we learn, that if any intercourse took place between them, it must have been after the publication of the *Treatise of Human Nature*. "I have sent the Bishop of Bristol a copy; but could not wait upon him with your letter after he had arrived at that dignity. At least, I thought it would be to no purpose after I began the printing."² In a subsequent letter to the same correspondent, written in 1742, he expresses his satisfaction at the favourable opinion which he understood Dr Butler had formed of his volume of *Essays*, then recently published, and augurs well from this circumstance of the success of his book. "I am told that Dr Butler has every where recommended them, so that I hope they will have some success."³

These particulars, trifling as they may appear to some, seemed to me, for more reasons than one, not unworthy of notice in this sketch. Independently of the pleasing record they afford of the mutual respect entertained by the eminent men to whom they relate, for each other's philosophical talents, they have a closer connection with the history of metaphysical and moral inquiry in this island, than might be suspected by those who have not

¹ For the rest of the letter, see *Memoirs of the Life and Writings of Lord Kames*, by Lord Woodhouselee, Vol. I. p. 84, *et seq.*

² *Memoirs of the Life and Writings of Lord Kames*, Vol. I. p. 92.

³ *Ibid.* p. 401. The *Essays* here referred to were the first part of the *Essays Moral, Political, and Literary*, published in 1742. The elegant author of these memoirs has inadvertently confounded this volume with the second part of that work, containing the *Political Discourses* (properly so called), which did not appear till ten years afterwards.

a very intimate acquaintance with the writings of both. Dr Butler was, I think, the first of Mr Locke's successors who clearly perceived the dangerous consequences likely to be deduced from his account of the origin of our ideas literally interpreted; and although he has touched on this subject but once, and that with his usual brevity, he has yet said enough to show, that his opinion with respect to it was the same with that formerly contended for by Cudworth, in opposition to Gassendi and Hobbes, and which has since been revived in different forms by the ablest of Mr Hume's antagonists.¹ With these views, it may be reasonably supposed, that he was not displeased to see the consequences of Locke's doctrine so very logically and forcibly pushed to their utmost limits, as the most effectual means of rousing the attention of the learned to a re-examination of this fundamental principle. That he was perfectly aware, before the publication of Mr Hume's work, of the encouragement given to scepticism by the logical maxims then in vogue, is evident from the concluding paragraph of his short *Essay on Personal Identity*. Had it been published a few years later, nobody would have doubted, that it had been directly pointed at the general strain and spirit of Mr Hume's philosophy.

" But though we are thus certain, that we are the same agents or living beings *now*, which we were as far back as our remembrance reaches; yet it is asked, Whether we may not possibly be deceived in it? And this question may be asked at the end of any demonstration whatever, because it is a question concerning the truth of perception by memory. And he who can doubt, whether perception by memory can in this case be depended on, may doubt also whether perception by deduction and reasoning, which also includes memory, or indeed whether intuitive perception can. Here then we can go no farther. For it is ridiculous to attempt to prove the truth of those perceptions whose truth we can no otherwise prove than by other perceptions of exactly the same kind with them, and which there is just the same ground to suspect; or to attempt to prove the truth of our faculties, which can no otherwise be proved, than by the use or means of those very suspected faculties themselves."²

It is, however, less as a speculative metaphysician, than as a philosophical inquirer into

¹ See the short *Essay on Personal Identity*, at the end of Butler's *Analogy*; and compare the second paragraph with the remarks on this part of Locke's *Essay* by Dr Price. (*Review of the Principal Questions and Difficulties relating to Morals*, pp. 49, 50. 3d Ed. Lond. 1787.)

² I must not, however, be understood as giving unqualified praise to this *Essay*. It is by no means free from the old scholastic jargon, and contains some reasoning which, I may confidently assert, the author would not have employed, had it been written fifty years later. Whoever takes the trouble to read the paragraph beginning with these words, "*Thirdly*, Every person is conscious," &c. will immediately perceive the truth of this remark. I mention it as a proof of the change to the better, which has taken place since Butler's time, in the mode of thinking and writing on Metaphysical questions.

the principles of morals, that I have been induced to associate the name of Butler with that of Hume. And, on this account, it may be thought that it would have been better to delay what I have now said of him till I come to trace the progress of Ethical Science during the eighteenth century. To myself it seemed more natural and interesting to connect this historical or rather biographical digression, with the earliest notice I was to take of Mr Hume as an author. The numerous and important hints on metaphysical questions which are scattered over Butler's works, are sufficient of themselves to account for the space I have allotted to him among Locke's successors; if, indeed, any apology for this be necessary, after what I have already mentioned, of Mr Hume's ambition to submit to his judgment the first fruits of his metaphysical studies.

The remarks hitherto made on the *Treatise of Human Nature* are confined entirely to the first volume. The speculations contained in the two others, on *Morals*, on the *Nature and Foundations of Government*, and on some other topics connected with political philosophy, will fall under our review afterwards.

Dr Reid's *Inquiry into the Human Mind* (published in 1764) was the first direct attack which appeared in Scotland upon the sceptical conclusions of Mr Hume's philosophy. For my own opinion of this work I must refer to one of my former publications.¹ It is enough to remark here, that its great object is to refute the *Ideal Theory* which was then in complete possession of the schools, and upon which Dr Reid conceived that the whole of Mr Hume's philosophy, as well as the whole of Berkeley's reasonings against the existence of matter, was founded. According to this theory we are taught, that "nothing is perceived but what is in the mind which perceives it; that we do not really perceive things that are external, but only certain images and pictures of them imprinted upon the mind, which are called impressions and ideas."—"This doctrine (says Dr Reid on another occasion) I once believed so firmly, as to embrace the whole of Berkeley's system along with it; till finding other consequences to follow from it, which gave me more uneasiness than the want of a material world, it came into my mind, more than forty years ago, to put the question, What evidence have I for this doctrine, that all the objects of my knowledge are ideas in my own mind? From that time to the present, I have been candidly and impartially, as I think, seeking for the evidence of this principle; but can find none, excepting the authority of philosophers."

On the refutation of the ideal theory, contained in this and his other works, Dr Reid himself was disposed to rest his chief merit as an author. "The merit (says he in a letter

¹ See *Biographical Memoirs*, Edin. 1811.

to Dr James Gregory) of what you are pleased to call *my Philosophy*, lies, I think, chiefly in having called in question the common theory of ideas or images of things in the mind being the only objects of thought; a theory founded on natural prejudices, and so universally received as to be interwoven with the structure of language. Yet were I to give you a detail of what led me to call in question this theory, after I had long held it as self-evident and unquestionable, you would think, as I do, that there was much of chance in the matter. The discovery was the birth of time, not of genius; and Berkeley and Hume did more to bring it to light than the man that hit upon it. I think there is hardly any thing that can be called *mine* in the philosophy of the mind, which does not follow with ease from the detection of this prejudice.

“ I must, therefore, beg of you, most earnestly, to make no contrast in my favour to the disparagement of my predecessors in the same pursuits. I can truly say of them, and shall always avow, what you are pleased to say of me, that, but for the assistance I have received from their writings, I never could have wrote or thought what I have done.”¹

When I reflect on the stress thus laid by Dr Reid on this part of his writings, and his frequent recurrence to the same argument whenever his subject affords him an opportunity of forcing it upon the attention of his readers, I cannot help expressing my wonder, that Kant and other German philosophers, who appear to have so carefully studied those passages in Reid, which relate to Hume's Theory of Causation, should have overlooked en-

¹ An ingenious and profound writer, who, though intimately connected with Mr Hume in habits of friendship, was not blind to the vulnerable parts of his Metaphysical System, has bestowed, in the latest of his publications, the following encomium on Dr Reid's *Philosophical Works*.

“ The author of an *Inquiry into the Mind*, and of subsequent *Essays on the Intellectual and Active Powers of Man*, has great merit in the effect to which he has pursued this history. But, considering the point at which the science stood when he began his inquiries, he has, perhaps, no less merit in having removed the mist of hypothesis and metaphor, with which the subject was enveloped; and, in having taught us to state the facts of which we are conscious, not in figurative language, but in the terms which are proper to the subject. In this it will be our advantage to follow him; the more that, in former theories, so much attention had been paid to the introduction of *ideas* or *images* as the elements of knowledge, that the belief of any external existence or prototype has been left to be inferred from the mere idea or image; and this inference, indeed, is so little founded, that many who have come to examine its evidence have thought themselves warranted to deny it altogether. And hence the scepticism of ingenious men, who, not seeing a proper access to knowledge through the medium of ideas, without considering whether the road they had been directed to take was the true or false one, denied the possibility of arriving at the end.” (*Principles of Moral and Political Science*, by Dr Adam Ferguson, Vol. I. pp. 75, 76.)

The work from which this passage is taken contains various important observations connected with the Philosophy of the Human Mind; but as the taste of the author led him much more strongly to moral and political speculations, than to researches concerning the intellectual powers of man, I have thought it right to reserve any remarks which I have to offer on his philosophical merits for the last part of this Discourse.

tirely what he himself considered as the most original and important of all his discussions; more especially as the conclusion to which it leads has been long admitted, by the best judges in this island, as one of the few propositions in metaphysical science completely established beyond the reach of controversy. Even those who affect to speak the most lightly of Dr Reid's contributions to the philosophy of the human mind, have found nothing to object to his reasonings against the ideal theory, but that the absurdities involved in it are too glaring to require a serious examination.¹ Had these reasonings been considered in the same light in Germany, it is quite impossible that the analogical language of Leibnitz, in which he speaks of the soul as a *living mirror of the universe*, could have been again revived; a mode of speaking liable to every objection which Reid has urged against the ideal theory. Such, however, it would appear, is the fact. The word *Representation* (*Vorstellung*) is now the German substitute for *Idea*: nay, one of the most able works which Germany has produced since the commencement of its new philosophical era, is entitled *Nova Theoria Facultatis Representativæ Humanæ*. In the same work, the author has prefixed, as a motto to the second book, in which he treats of "the *Representative Faculty* in general," the following sentence from Locke, which he seems to have thought himself entitled to assume as a first principle: "Since the mind, in

¹ I allude here more particularly to Dr Priestley, who, in a work published in 1774, alleged, that when philosophers called ideas the *images* of external things, they are only to be understood as speaking figuratively; and that Dr Reid has gravely argued against this metaphorical language, as if it were meant to convey a theory of perception. The same remark has been repeated over and over since Priestley's time, by various writers. I have nothing to add in reply to it to what I long ago stated in my *Philosophical Essays* (see Note H. at the end of that work), but the following short quotation from Mr Hume:—

"It seems evident, that, when men follow this blind and powerful instinct of nature, they always suppose the very images, presented by the senses, to be the external objects, and never entertain any suspicion, that the one are nothing but *representations* of the other. * * * But this universal and primary opinion of all men is soon destroyed by the slightest philosophy, which teaches us, that nothing can ever be present to the mind but an *image* or perception, and that the senses are only the inlets through which these images are conveyed, without being able to produce any immediate intercourse between the mind and the object. The table which we see seems to diminish as we remove farther from it; but the real table, which exists independent of us, suffers no alteration. It was, therefore, nothing but its image which was present to the mind. These are the obvious dictates of reason." (*Essay on the Academical Philosophy*.)

Is not this analogical theory of perception the principle on which the whole of Berkeley's reasonings against the existence of the material world, and of Hume's scepticism on the same subject, are founded?

The same analogy still continues to be sanctioned by some English philosophers of no small note. Long after the publication of Dr Reid's *Inquiry*, Mr Horne Took quoted with approbation the following words of J. C. Scaliger: "Sicut in speculo ea quæ videntur non sunt, sed eorum *species*: ita quæ intelligimus, ea sunt re ipsâ extra nos, eorumque *species* in nobis. EST ENIM QUASI RERUM SPECULUM INTELLECTUS NOSTER; CUI, NISI PER SENSUM REPRESENTENTUR RES, NIHIL EST IPSE."—(J. C. Scaliger, *de Causis*, L. L. cap. lxvi.) *Diversions of Purley*, Vol. I. p. 35, 2d Edition.)

all its thoughts and reasonings, hath no other *immediate* object but its own *ideas* (*representations*), which it alone does or can contemplate; it is evident that our knowledge is only concerned about them."—(Lock's *Essay*, B. IV. ch. 1.) In a country where this metaphysical jargon still passes current among writers of eminence, it is vain to expect that any solid progress can be made in the inductive philosophy of the human mind. A similar remark may be extended to another country, where the title of *Idéologie* (a word which takes for granted the truth of the hypothesis which it was Reid's great aim to explode) has been lately given to the very science in which the theory of *Ideas* has been so clearly shown to have been, in all ages, the most fruitful source of error and absurdity.¹

Of the other works by Scottish metaphysicians, which appeared soon after the *Inquiry into the Human Mind*, I have not left myself room to speak. I know of none of them from which something important may not be learned; while several of them (particularly those of Dr Campbell) have struck out many new and interesting views. To one encomium all of them are well entitled, that of aiming steadily at the advancement of useful knowledge and of human happiness. But the principles on which they have proceeded have so close an affinity to those of Dr Reid, that I could not, without repeating over what I have already said, enter into any explanation concerning their characteristic doctrines.

On comparing the opposition which Mr Hume's scepticism encountered from his own countrymen, with the account formerly given of the attempts of some German philosophers to refute his Theory of Causation, it is impossible not to be struck with the coincidence between the leading views of his most eminent antagonists. This coincidence one would have been disposed to consider as purely accidental, if Kant, by his petulant sneers at Reid, Beattie, and Oswald, had not expressly acknowledged, that he was not acquainted with their writings. As for the great discovery, which he seems to claim as his own,—that the ideas of Cause and Effect, as well as many others, are derived from the *pure understanding* without any aid from experience, it is nothing more than a repetition, in very nearly the same terms, of what was advanced a century before by Cudworth, in reply to Hobbes and Gassendi, and borrowed speedily by Cudworth from the reasonings of Socrates, as reported by Plato, in answer to the scepticism of Protagoras. This recur-

¹ In censuring these metaphysical terms, I am far from supposing that the learned writers who have employed them have been all misled by the theoretical opinions involved in their language. Reinhold has been more particularly careful in guarding against such a misapprehension. But it cannot, I think, be doubted that the prevalence of such a philosophy must have a tendency to divert the attention from a just view of the mental phenomena, and to infuse into the mind of the young inquirer very false conceptions of the manner in which these phenomena ought to be studied.

rence, under different forms, of the same metaphysical controversies, which so often surprises and mortifies us in the history of literature, is an evil which will probably always continue, more or less, even in the most prosperous state of philosophy. But it affords no objection to the utility of metaphysical pursuits. While the sceptics keep the field, it must not be abandoned by the friends of sounder principles; nor ought they to be discouraged from their ungrateful task, by the reflection, that they have probably been anticipated, in every thing they have to say, by more than one of their predecessors. If anything is likely to check this periodical return of a mischief so unpropitious to the progress of useful knowledge, it seems to be the general diffusion of that historical information concerning the literature and science of former times, of which it is the aim of these Preliminary Dissertations to present an outline. Should it fail in preventing the occasional revival of obsolete paradoxes, it will, at least, diminish the wonder and admiration with which they are apt to be regarded by the multitude.

And here I cannot refrain from remarking the injustice with which the advocates for truth are apt to be treated; and by none more remarkably than by that class of writers who profess the greatest zeal for its triumph. The importance of their labours is discredited by those who are the loudest in their declamations and invectives against the licentious philosophy of the present age; inasmuch that a careless observer would be inclined to imagine (if I may borrow Mr Hume's words on another occasion), that the battle was fought, "not by the men at arms, who manage the pike and the sword, but by the trumpeters, drummers, and musicians, of the army."

These observations may serve, at the same time, to account for the slow and (according to some persons) imperceptible advances of the philosophy of the human mind, since the publication of Locke's *Essay*. With those who still attach themselves to that author, as an infallible guide in metaphysics, it is in vain to argue; but I would willingly appeal to any of Locke's rational and discriminating admirers, whether much has not been done by his successors, and, among others, by members of our northern universities, towards the illustration and correction of such of his principles as have furnished, both to English and French sceptics, the foundation of their theories.¹ If this be granted, the way has, at

¹ According to Dr. Priestley, the labours of these commentators on Locke have done more harm than good. "I think Mr. Locke has been hasty in concluding that there is some other source of our ideas besides the external senses; but the rest of his system appears to me and others to be the corner stone of all just and rational knowledge of ourselves."

"This solid foundation, however, has lately been attempted to be overturned by a set of pretended philosophers, of whom the most conspicuous and assuming is Dr Reid, Professor of Moral Philosophy in the Univer-

least, been cleared and prepared for the labours of our posterity; and neither the cavils of the sceptic, nor the refutation of them by the sounder logician, can be pronounced to be useless to mankind. Nothing can be juster or more liberal than the following reflection of Reid: "I conceive the sceptical writers to be a set of men, whose business it is to pick holes in the fabric of knowledge wherever it is weak and faulty; and when those places are properly repaired, the whole building becomes more firm and solid than it was formerly."—(*Inquiry into the Human Mind. Dedication.*)

There is, indeed, one point of view, in which, it must be owned, that Mr Hume's *Treatise* has had an unfavourable effect (and more especially in Scotland) on the progress of Metaphysical Science. Had it not been for the zeal of some of his countrymen to oppose the sceptical conclusions, which they conceived it to be his aim to establish, much of that ingenuity which has been wasted in the refutation of his sophistry (or, to speak more correctly, in combating the mistaken principles on which he proceeded) would, in all probability, have been directed to speculations more immediately applicable to the business of life, or more agreeable to the taste of the present age. What might not have been expected from Mr Hume himself, had his powerful and accomplished mind been more frequently turned to the study of some parts of our nature (of those, for example, which are connected with the principles of criticism), in examining which, the sceptical bias of his disposition would have had fewer opportunities of leading him astray! In some fragments of this sort, which enliven and adorn his collection of *Essays*, one is at a loss whether more to admire the subtlety of his genius, or the solidity and good sense of his critical judgments.

Nor have these elegant applications of metaphysical pursuits been altogether overlooked by Mr Hume's antagonists. The active and adventurous spirit of Lord Kames, here, as in many other instances, led the way to his countrymen; and, due allowances being made for the novelty and magnitude of his undertaking, with a success far greater than could have been reasonably anticipated. The *Elements of Criticism*, considered as the first systematical attempt to investigate the metaphysical principles of the fine arts, possesses, in spite of its numerous defects both in point of taste and of philosophy, infinite merits, and will ever be regarded as a literary wonder by those who know how small a portion of his time it was possible for the author to allot to the composition of it, amidst the imperious and multifarious duties of a most active and useful life. Campbell and Gerard.

sity of Glasgow."—(*Exam. of Reid, Beattie, and Oswald*, p. 5.)—As to Mr Hume, Dr Priestley says, "In my opinion, he has been very ably answered, again and again, upon more solid principles than those of this new common sense; and I beg leave to refer to the two first volumes of my *Institutes of Natural and Revealed Religion*.—(*Examination of Reid &c.* Preface, p. xxvii.)

with a sounder philosophy, and Beattie, with a much more lively relish for the Sublime and the Beautiful, followed afterwards in the same path; and have all contributed to create and to diffuse over this island a taste for a higher and more enlightened species of criticism than was known to our forefathers. Among the many advantageous results with which this study has been already attended, the most important, undoubtedly, is the new and pleasing avenue which it has opened to an analysis of the laws which regulate the intellectual phenomena; and the interest which it has thus lent, in the estimation of men of the world, to inquiries which, not many years before, were seldom heard of, but within the walls of an university.

Dr Reid's two volumes of *Essays on the Intellectual and on the Active Powers of Man* (the former of which appeared in 1785, and the latter in 1788) are the latest philosophical publications from Scotland of which I shall at present take notice. They are less highly finished, both in matter and in form, than his *Inquiry into the Human Mind*. They contain also some repetitions, to which, I am afraid, I must add a few trifling inconsistencies of expression, for which the advanced age of the author, who was then approaching to fourscore, claims every indulgence from a candid reader. Perhaps, too, it may be questioned, whether, in one or two instances, his zeal for an important conclusion has not led him to avail himself of some dubious reasonings, which might have been omitted without any prejudice to his general argument. "The value of these volumes, however (as I have elsewhere remarked), is inestimable to future adventurers in the same arduous inquiries, not only in consequence of the aids they furnish as a rough draught of the field to be examined, but by the example they exhibit of a method of investigation on such subjects, hitherto very imperfectly understood, even by those philosophers who call themselves the disciples of Locke. It is by the logical rigour of this method, so systematically pursued in all his researches, still more than by the importance of his particular conclusions, that he stands so conspicuously distinguished among those who have hitherto prosecuted analytically the study of man."¹

His acquaintance with the metaphysical doctrines of his predecessors does not appear to have been very extensive; with those of his own contemporaries it was remarkably deficient. I do not recollect that he has anywhere mentioned the names either of Condillac or of D'Alembert. It is impossible not to regret this, not only as it has deprived us of his critical judgments on some celebrated theories, but as it has prevented him from enlivening his works with that variety of historical discussion so peculiarly agreeable in these abstract researches.

On the other hand, Dr Reid's limited range of metaphysical reading, by forcing him to draw the materials of his philosophical speculations almost entirely from his own reflections, has given to his style, both of thinking and of writing, a characteristic unity and simplicity seldom to be met with in so voluminous an author. He sometimes, indeed, repeats, with an air of originality, what had been previously said by his predecessors; but on these, as on all other occasions, he has at least the merit of thinking for himself, and of sanctioning, by the weight of his unbiassed judgment, the conclusions which he adopts. It is this uniformity of thought and design, which, according to Dr Butler, is the best test of an author's sincerity; and I am apt to regard it also, in these abstruse disquisitions, as one of the surest marks of liberal and unfettered inquiry.

In comparing Dr Reid's publications at different periods of his life, it is interesting to observe his growing partiality for the aphoristical style. Some of his *Essays on the Intellectual and Active Powers of Man* are little more than a series of detached paragraphs, consisting of leading thoughts, of which the reader is left to trace the connection by his own sagacity. To this aphoristical style it is not improbable that he was partly led by the indolence incident to advanced years, as it relieved him from what Boileau justly considered as the most difficult task of an author, the skilful management of *transitions*.¹ In consequence of this want of continuity in his compositions, a good deal of popular effect is unavoidably lost; but, on the other hand, to the few who have a taste for such inquiries, and who value books chiefly as they furnish exercise to their own thoughts (a class of readers who are alone competent to pronounce a judgment on metaphysical questions), there is a peculiar charm in a mode of writing, so admirably calculated to give *relief* to the author's ideas, and to awaken, at every sentence, the reflections of his readers.

When I review what I have now written on the history of Metaphysics in Scotland, since the publication of Mr Hume's *Treatise*, and at the same time recollect the laurels which, during the same period, have been won by Scottish authors, in every other department of literature and of science, I must acknowledge that, instead of being mortified at the slender amount of their contributions to the philosophy of the human mind, I am more disposed to wonder at their successful perseverance in cultivating a field of study, where the approbation of a few enlightened and candid judges is the only reward to which their ambition could aspire. Small as their progress may hitherto have been, it will at

— ¹ Boileau is said, by the younger Racine, to have made this remark in speaking of La Bruyere: "Il disoit que La Bruyere s'étoit épargné le plus difficile d'un ouvrage en s'épargnant les transitions." (*Mémoire sur la Vie de Jean Racine.*)

least not suffer by a comparison with what has been accomplished by their contemporaries in any other part of Europe.

It may not be useless to add in this place, that, if little has yet been done, the more ample is the field left for the industry of our successors. The compilation of a *Manual of Rational Logic*, adapted to the present state of science and of society in Europe, is a *desideratum* which, it is to be hoped, will at no distant period be supplied. It is a work, certainly, of which the execution has been greatly facilitated by the philosophical labours of the last century. The varieties of intellectual character among men present another very interesting object of study, which, considering its practical utility, has not yet excited, so much as might have been expected, the curiosity of our countrymen. Much, too, is still wanting to complete the theory of evidence. Campbell has touched upon it with his usual acuteness, but he has attempted nothing more than an illustration of a very few general principles. Nor has he turned his attention to the various illusions of the imagination, and of the passions, by which the judgment is liable to be warped in the estimates it forms of moral evidence in the common affairs of life. This is a most important inquiry, considering how often the lives and fortunes of men are subjected to the decisions of illiterate persons concerning circumstantial proofs; and how much the success or failure of every individual in the conduct of his private concerns turns on the sagacity or rashness with which he anticipates future contingencies. Since the time when Campbell wrote, an attempt has been made by Condorcet¹ and some other French writers, to apply a mathematical calculus to moral and political truths; but though much metaphysical ingenuity, as well as mathematical skill, have been displayed in carrying it into execution, it has not yet led to any useful practical results. Perhaps it may even be questioned, whether, in investigating truths of this sort, the intellectual powers can derive much aid from the employment of such an organ. To define accurately and distinctly the limits of its legitimate province, still remains a *desideratum* in this abstruse part of logic.

Nearly connected with this subject are the metaphysical principles assumed in the mathematical Calculation of Probabilities; in delivering which principles, some foreign mathematicians, with the illustrious La Place at their head, have blended, with many unquestionable and highly interesting conclusions, various moral paralogisms of the most pernicious tendency. A critical examination of these paralogisms, which are apt to escape the attention of the reader amid the variety of original and luminous discussions with which

¹ *Essai sur l'application de l'Analyse à la Probabilité des Décisions rendues à la pluralité des Voix.*

they are surrounded, would, in my humble apprehension, be one of the most essential services which could at present be rendered to true philosophy. In the mind of La Place, their origin may be fairly traced to an ambition, not altogether unnatural in so transcendent a genius, to extend the empire of his favourite science over the moral as well as the material world.¹ I have mentioned but a few out of the innumerable topics which crowd upon me as fit objects of inquiry for the rising generation.² Nor have I been guided in my selection of these by any other consideration, than their peculiar adaptation to the actual circumstances of the philosophical world.

Should such men as Hume, Smith, and Reid again arise, their curiosity would, in all probability, be turned to some applications of metaphysical principles of a more popular and practical nature than those which chiefly engaged their curiosity. At the same time, let us not forget what a step they made beyond the scholastic philosophy of the preceding age; and how necessary this step was as a preliminary to other researches bearing more directly and palpably on human affairs.

The most popular objection hitherto made to our Scottish metaphysicians is, that, in treating of human nature, they have overlooked altogether the corporeal part of our frame. From the contempt which they have uniformly expressed for all physiological theories concerning the intellectual phenomena, it has been concluded, that they were disposed to consider the human mind as altogether independent of the influence of physical causes. Mr Belsham has carried this charge so far, as to sneer at Dr Reid's inconsistency for having somewhere acknowledged, "in opposition to his systematical principles, that a certain constitution or state of the brain is necessary to memory." In reply to this charge, it may be confidently asserted, that no set of philosophers, since the time of Lord Bacon, have entertained juster views on this subject than the school to which Dr Reid belonged. In proof of this, I need only appeal to the *Lectures on the Duties and Qualifications of a Physician*, by the late learned and ingenious Dr John Gregory. Among the different articles connected with the natural history of the human species, which he has there recommended to the examination of the medical student, he lays particular stress on "the laws of union

¹ The paralogisms to which I allude did not fall within the scope of the admirable criticism on this work in the *Edinburgh Review*.

² Among these, the most prominent is the *Natural or Theoretical History of Language* (including under this title *written* as well as *oral* language), a subject which will probably continue to furnish new problems to human ingenuity, in the most improved state of human knowledge. It is not surprising, that an art which lays the foundation of all the others, and which is so intimately connected with the exercise of reason itself, should leave behind it such faint and obscure traces of its origin and infancy.

between the mind and body, and the mutual influence they have upon one another." "This (he observes) is one of the most important inquiries that ever engaged the attention of mankind, and almost equally necessary in the sciences of morals and of medicine." It must be remarked, however, that it is only the *laws* which regulate the union between mind and body (the same class of *facts* which Bacon called the *doctrina de fœdere*), which are here pointed out as proper objects of philosophical curiosity; for as to any *hypothesis* concerning the *manner* in which the union is carried on, this most sagacious writer was well aware, that they are not more unfavourable to the improvement of logic and of ethics, than to a skilful and judicious exercise of the healing art.

I may perhaps form too high an estimate of the progress of knowledge during the last fifty years; but I think I can perceive, within the period of my own recollection, not only a change to the better in the Philosophy of the Human Mind, but in the speculations of medical inquirers. Physiological theories concerning the functions of the nerves in producing the intellectual phenomena have pretty generally fallen into contempt: and, on the other hand, a large accession has been made to our stock of well authenticated facts, both with respect to the influence of body on mind, and of mind upon body. As examples of this, it is sufficient to mention the experimental inquiries instituted, in consequence of the pretended cures effected by means of Animal Magnetism and of Tractors; to which may be added, the philosophical spirit evinced in some late publications on Insanity.

Another objection, not so entirely groundless, which has been made to the same school, is, that their mode of philosophising has led to an unnecessary multiplication of our *internal senses and instinctive determinations*. For this error, I have elsewhere attempted to account and to apologize.¹ On the present occasion I shall only remark, that it is at least a safer error than the opposite extreme, so fashionable of late among our southern neighbours, of endeavouring to explain away, without any exception, all our *instinctive* principles, both speculative and practical. A literal interpretation of Locke's comparison of the infant mind to a *sheet of white paper* (a comparison which, if I am rightly informed, has not yet wholly lost its credit in all our universities), naturally predisposed his followers to embrace this theory, and enabled them to shelter it from a free examination, under the sanction of his supposed authority. Dr Paley, himself, in his earliest philosophical publication, yielded so far to the prejudices in which he had been educated, as to dispute the existence of the *moral faculty*;² although, in his more advanced years, he amply aton-

¹ *Biographical Memoirs*, p. 472.

² After relating, in the words of Valerius Maximus, the noted story of Caius Toranus, who betrayed his affectionate and excellent father to the triumvirate, Dr. Paley thus proceeds:

ed for this error of his youth, by the ingenuity and acuteness with which he combated the reasonings employed by some of his contemporaries, to invalidate the proofs afforded by the phenomena of *instinct*, of the existence of a designing and provident cause. In this part of his work, he has plainly in his eye the *Zoonomia* of Dr Darwin,¹ where the same principles, of which Paley and others had availed themselves to disprove the existence of instinct and instinctive propensities in man, are eagerly laid hold of to disprove the existence of *instinct* in the brutes. Without such an extension of the argument, it was clearly perceived by Darwin, that sufficient evidences of the existence of a Designing Cause would be afforded by the phenomena of the lower animals; and, accordingly, he has employed much ingenuity to show, that all these phenomena may be accounted for by experience, or by the influence of pleasurable or painful sensations, operating *at the moment* on the animal frame.

In opposition to this theory, it is maintained by Paley, that it is by *instinct*, that

“ Now the question is, whether, if this story were related to the wild boy caught some years ago in the woods of Hanover, or to a savage without experience and without instruction, cut off in his infancy from all intercourse with his species, and consequently under no possible influence of example, authority, education, sympathy, or habit; whether, I say, such a one would feel, upon the relation, any degree of that *sentiment of disapprobation of Toranius's conduct* which we feel or not?”

“ They who maintain the existence of a moral sense, of innate maxims, of a natural conscience—that the love of virtue and hatred of vice are instinctive, or the perception of right or wrong intuitive (all of which are only different ways of expressing the same opinion), affirm that he would.

“ They who deny the existence of a moral sense, &c. affirm that he would not.

“ And upon this issue is joined.” (*Principles of Moral and Political Philosophy*, B. I. Chap. 5.)

To those who are at all acquainted with the history of this dispute, it must appear evident that the question is here completely misstated; and that, in the whole of Dr Paley's subsequent argument on the subject, he combats a phantom of his own imagination. The opinion which he ascribes to his antagonists has been loudly and repeatedly disavowed by all the most eminent moralists who have disputed Locke's reasonings against *innate practical principles*; and is, indeed, so very obviously absurd, that it never could have been for a moment entertained by any person in his senses.

Did it ever enter into the mind of the wildest theorist to imagine that the sense of seeing would enable a man brought up, from the moment of his birth, in utter darkness, to form a conception of light and colours? But would it not be equally rash to conclude from the extravagance of such a supposition, that the sense of seeing is not an original part of the human frame?

The above quotation from Paley forces me to remark, farther, that, in combating the supposition of a *moral sense*, he has confounded together, as *only different ways of expressing the same opinion*, a variety of systems, which are regarded by all our best philosophers, not only as essentially distinct, but as in some measure standing in opposition to each other. The system of Hutcheson, for example, is identified with that of Cudworth. But although, in this instance, the author's logical discrimination does not appear to much advantage, the sweeping censure thus bestowed on so many of our most celebrated ethical theories, has the merit of throwing a very strong light on that particular view of the subject which it is the aim of his reasonings to establish, in contradiction to them all.

¹ See the section on Instinct. (Sect. XVI. of that work.)

is (according to his own definition), “by a propensity prior to experience, and independent of instruction,” “that the sexes of animals seek each other; that animals cherish their offspring; that the young quadruped is directed to the teat of its dam; that birds build their nest, and brood with so much patience upon their eggs; that insects, which do not sit upon their eggs, deposit them in those particular situations in which the young, when hatched, find their appropriate food; that it is instinct which carries the salmon, and some other fish, out of the sea into rivers, for the purpose of shedding their spawn in fresh water.”¹

In Dr Paley's very able and convincing reasonings on these various points, he has undoubtedly approached nearer to the spirit of what has been ironically called *Scottish philosophy*,² than any of Mr Locke's English disciples, since the time of Dr Butler: a circumstance which, when compared with the metaphysical creed of his earlier years, reflects the greatest honour on the candour and fairness of his mind, and encourages the hope, that this philosophy, where it is equally sound, will gradually and silently work its way among sincere inquirers after truth, in spite of the strong prejudices which many of our southern neighbours still appear to entertain against it. The extravagancies of Darwin, it is probable, first opened Dr Paley's eyes to the dangerous tendency of Locke's argument against innate principles, when inculcated without due limitations.³

With this very faint outline of the speculations of Locke's chief successors in Scot

¹ Paley's *Natural Theology*, p. 324.

² May I take the liberty of requesting the reader to compare a few pages of Dr Paley's Section on Instinct, beginning, “*I am not ignorant of the theory which resolves instinct into sensation*,” &c. with some remarks made by the author of this Dissertation, in an Account of the Life and Writings of Dr Reid? See the passage in section second, beginning thus, “*In a very original work, on which I have already hazarded some criticisms*,” &c. As both publications appeared about the same time (in the year 1802), the coincidence, in point of thought, must have been wholly accidental, and as such affords no slight presumption in favour of its soundness.

³ When Dr Paley published his *Principles of Moral and Political Philosophy*, he seems to have attached himself much too slavishly to the opinions of Bishop Law, to whom that work is inscribed. Hence, probably, his anxiety to disprove the existence of the moral faculty. Of the length to which Law was disposed to carry Locke's argument against innate principles, he has enabled us to judge by his own explicit declaration: “*I take implanted senses, instincts, appetites, passions, and affections, &c. to be a remnant of the old philosophy, which used to call every thing innate that it could not account for; and therefore heartily wish, that they were in one sense all eradicated, which was undoubtedly the aim of that great author last mentioned (Mr Locke), as it was a natural consequence of his first book.*” (Law's translation of Archbishop King *On the Origin of Evil*, p. 79, note.)

In justice, however, to Dr Law, it must be observed, that he appears to have been fully aware that the

land, prior to the close of Dr. Reid's literary labours, I shall for the present finish my review of the metaphysical pursuits of the eighteenth century. The long period which has since elapsed has been too much crowded with great political events to favour the growth of abstract science in any of its branches; and of the little which appears to have been done, during this interval, in other parts of Europe, towards the advancement of true philosophy, the interrupted communication between this island and the Continent left us for many years in a state of almost total ignorance. This chasm, in our information concerning foreign literature, it may not be a difficult task for younger men to supply. At my time of life it would be folly to attempt it; nor, perhaps, is any author, who has himself been so frequently before the public, the fittest person to form an impartial estimate of the merits of his living contemporaries. Now, however, when peace is at length restored to the world, it may reasonably be hoped that the human mind will again resume her former career with renovated energy; and that the nineteenth century will not yield to the eighteenth in furnishing materials to those who may hereafter delight to trace the progressive improvement of their species. In the meantime, instead of indulging myself in looking forward to the future, I shall conclude this section with a few general reflections suggested by the foregoing retrospect.

Among these reflections, what chiefly strikes my own mind is the extraordinary change which has gradually and insensibly taken place since the publication of Locke's *Essay*, in the meaning of the word *Metaphysics*; a word formerly appropriated to the ontology and pneumatology of the schools, but now understood as equally applicable to all those inquiries, which have, for their object, to trace the various branches of human knowledge to their first principles in the constitution of our nature.¹ This change can be accounted for

dispute about innate principles was in a great measure verbal. "It will really (says he) come to the same thing with regard to the moral attributes of God and the nature of virtue and vice, whether the Deity has *implanted* these instincts and affections in us, or has framed and disposed us in such a manner, has given us such powers, and placed us in such circumstances, that we must *necessarily acquire them*." (*Ibid.*) But if Dr Law was aware of this, why should he and his followers have attached such infinite importance to the controversy?

¹ The following is the account of Metaphysics given by Hobbes.—"There is a certain *Philosophia prima*, on which all other Philosophy ought to depend; and consisteth principally in right limiting of the significations of such appellations, or names, as are of all others the most universal: which limitations serve to avoid ambiguity, and equivocation in reasoning; and are commonly called Definitions, such as are the Definitions of Body, Time, Place, Matter, Form, Essence, Subject, Substance, Accident, Power, Act, Finite, Infinite, Quantity, Quality, Motion, Action, Passion, and divers others, necessary to the explaining of a man's conceptions concerning the nature and generation of bodies. The explication (that is, the settling of the meaning) of which, and the like terms, is commonly in the schools called *Metaphysics*." (*Moral and Political Works*. Folio Edit. London, 1750. p. 399.)

only by a change in the philosophical pursuits of Locke's successors; a change from the idle abstractions and subtleties of the dark ages, to studies subservient to the culture of the understanding; to the successful exercise of its faculties and powers; and to a knowledge of the great ends and purposes of our being. It may be regarded, therefore, as a palpable and incontrovertible proof of a corresponding progress of reason in this part of the world.

On comparing together the multifarious studies now classed together under the title of Metaphysics, it will be found difficult to trace any common circumstance but this, that they all require the same sort of mental exertion for their prosecution; the exercise, I mean, of that power (called by Locke *Reflection*) by which the mind turns its attention inwards upon its own operations, and the subjects of its own consciousness. In researches concerning our intellectual and active powers, the mind directs its attention to the faculties which it exercises, or to the propensities which put these faculties in motion. In all the other inquiries which fall under the province of the Metaphysician, the materials of his reasoning are drawn chiefly from his own internal resources. Nor is this observation less applicable to speculations which relate to things external, than to such as are confined to the thinking and sentient principle within him. In carrying on his researches (for example) concerning *hardness, softness, figure, and motion*, he finds it not less necessary to retire within himself, than in studying the laws of imagination or memory. Indeed, in such cases, the whole aim of his studies is to obtain a more precise definition of his *ideas*, and to ascertain the occasions on which they are formed.

From this account of the nature and object of metaphysical science, it may be reasonably expected, that those with whom it is a favourite and habitual pursuit, should acquire a more than ordinary capacity of retiring, at pleasure, from the external to the internal world. They may be expected also to acquire a disposition to examine the origin of whatsoever combinations they may find established in the fancy, and a superiority to the casual associations which warp common understandings. Hence an accuracy and a subtlety in their distinctions on all subjects, and those peculiarities in their views which are characteristic of unbiassed and original thinking. But, perhaps, the most valuable fruit of their researches, is that scrupulous precision in the use of language, upon which, more than upon any one circumstance whatever, the logical accuracy of our reasonings, and the justness of our conclusions, essentially depend. Accordingly it will be found, on a review of the history of the moral sciences, that the most important steps which have been made in some of those, apparently the most remote from metaphysical pursuits (in the science, for example, of political economy), have been made by men trained to the exercise of their intellectual

powers by early habits of abstract meditation. To this fact Burke probably alluded, when he remarked, that “by turning the soul inward on itself, its forces are concentrated, and are fitted for stronger and bolder flights of science; and that in such pursuits, whether we take, or whether we lose the game, the chace is certainly of service.” The names of Locke, of Berkeley, of Hume, of Quesnai, of Turgot, of Morellet, and above all, of Adam Smith, will at once illustrate the truth of these observations, and show, that, in combining together, in this Dissertation, the sciences of Metaphysics, of Ethics, and of Politics, I have not adopted an arrangement altogether capricious.¹

In farther justification of this arrangement, I might appeal to the popular prejudices so industriously fostered by many, against these three branches of knowledge, as ramifications from one common and most pernicious root. How often have Mr Smith's reasonings in favour of the freedom of trade been ridiculed as *metaphysical* and visionary! Nay, but a few years have elapsed, since this epithet (accompanied with the still more opprobrious terms of *Atheistical* and *Democratical*) was applied to the argument then urged against the morality and policy of the slave-trade; and, in general, to every speculation in which any appeal was made to the beneficent arrangements of nature, or to the progressive improvement of the human race. Absurd as this language was, it could not, for a moment, have obtained any currency with the multitude, had there not been an obvious connection between these liberal doctrines, and the well known habits of logical thinking, which so eminently distinguished their authors and advocates. Whatever praise, therefore, may be due to the fathers of the modern science of political economy, belongs, at least in part (according to the acknowledgment of their most decided adversaries), to those abstract studies by which they were prepared for an analytical investigation of its first and fundamental principles.

Other connections and affinities between Political Economy and the Philosophy of the

¹ It furnishes no objection to these remarks, that some of our best treatises on questions of political economy have proceeded from men who were strangers to metaphysical studies. It is enough for my purpose if it be granted, that it was by habits of metaphysical thinking that the minds of those authors were formed, by whom political economy was first exalted to the dignity of a science. To a great proportion even of the learned, the rules of a sound logic are best taught by examples, and when a precise and well-defined phraseology is once introduced, the speculations of the most ordinary writers assume an appearance (sometimes, it must be owned, a very fallacious one) of depth and consistency.

Fontenelle remarks, that a single great man is sufficient to accomplish a change in the taste of his age, and that the perspicuity and method for which Descartes was indebted to his mathematical researches, were successfully copied by many of his contemporaries who were ignorant of mathematics. A similar observation will be found to apply, with still greater force, to the models of metaphysical analysis and of logical discussion, exhibited in the political works of Hume and of Smith.

Human Mind will present themselves afterwards. At present I purposely confine myself to that which is most obvious and indisputable.

The influence of metaphysical studies may be also perceived in the philosophical spirit so largely infused into the best historical compositions of the last century. This spirit has, indeed, been often perverted to pernicious purposes; but who can doubt, that, on the whole, both history and philosophy have gained infinitely by the alliance?

How far a similar alliance has been advantageous to our poetry, may be more reasonably questioned. But on the most unfavourable supposition it must be admitted, that the number of poetical readers has thereby been greatly increased, and the pleasures of imagination proportionally communicated to a wider circle. The same remark may be extended to the study of philosophical criticism. If it has not contributed to the encouragement of original genius in the fine arts, it has been followed by a much more beneficial result in diffusing a relish for the beautiful and the elegant; not to mention its influence in correcting and fixing the public taste, by the precision and steadiness of the principles to which it appeals.¹

Another instance, still more important, of the practical influence of metaphysical science, is the improvement which, since the time of Locke, has become general in the conduct of education, both private and public. In the former case, the fact is universally acknowledged. But even in our universities (notwithstanding the proverbial aversion of most of them to everything which savours of innovation) what a change has been gradually accomplished since the beginning of the eighteenth century! The studies of Ontology, of Pneumatology, and of Dialectics, have been supplanted by that of the Human Mind, conducted with more or less success, on the plan of Locke's *Essay*; and, in a few seats of learning, by the studies of Bacon's Method of Inquiry, of the Principles of Philosophical Criticism, and of the Elements of Political Economy. In all this an approach has been made or attempted, to what Locke so earnestly recommended to parents, "that their children's time should be spent in acquiring what may be useful to them when they come to be men." Many other circumstances, no doubt, have contributed their share in producing this revolution; but what individual can be compared to Locke in giving the first impulse to that spirit of reform by which it has been established?²

¹ See some admirable remarks on this subject by Gray, in his comments on the *Io* of Plato. (Edition of Gray, by Mathias.)

² Under this head of education may also be mentioned the practical improvements which, during the course of the last century, have taken place in what Lord Bacon calls *the traditive part of logic*. I allude here not only to the new arrangements in the Lancastrian Schools, by which the diffusion of the art of reading among

In consequence of the operation of these causes, a sensible change has taken place in the style of English composition.¹ The number of idiomatical phrases has been abridg-

the poorer classes of the community is so wonderfully facilitated and extended, but to those admirable elementary works which have opened a ready and speedy access to the more recondite truths of the severer sciences. How much these have contributed to promote the progress of mathematical knowledge in France, may be judged of from an assertion of Condorcet, that two years spent under an able teacher now carry the student beyond the conclusions which limited the researches of Leibnitz and of Newton. The Essays lately published on this subject by M. Lacroix (*Essais sur l'Enseignement en Général, et sur celui des Mathématiques en particulier*. Paris, 1807) contain many valuable suggestions; and, beside their utility to those who are concerned in the task of instruction, may justly be considered as an accession to the Philosophy of the Human Mind.

¹ See some judicious remarks on this subject in Mr Godwin's *Inquirer*, p. 271. In the opinion of this author, "the English language is now written with more grammatical propriety than by the best of our ancestors; and with a much higher degree of energy and vigour. The spirit of philosophy has infused itself into the structure of our sentences." He remarks farther, in favour of the present style of English composition, "that it at once satisfies the understanding and the ear." The union of these two excellencies certainly constitutes the perfection of writing. Johnson boasts, and with truth, in the concluding paper of the *Rambler*, that he had "added something to our language in the elegance of its construction, and something in the harmony of its cadence," but what a sacrifice did he make to these objects, of conciseness, of simplicity, and of (what he has himself called) *Genuine Anglicism*. To accomplish the same ends, without any sacrifice of these higher merits, has been one of the chief aims of the most eminent among his successors.

As an instrument of thought and a medium of scientific communication, the English language appears to me, in its present state, to be far superior to the French. Diderot, indeed (a very high authority), has, with much confidence, asserted the contrary, and it is but fair to let him speak for himself: "J'ajouterois volontiers que la marche didactique et reglée à laquelle notre langue est assujettie la rend plus propre aux sciences; et que par les tours et les inversions que le Grec, le Latin, l'Italien, l'Anglois, se permettent, ces langues sont plus avantageuses pour les lettres: Que nous pouvons mieux qu'aucun autre peuple faire parler l'esprit: et que le bon sens choisiroit la langue Française; mais que l'Imagination et les passions donneroient la préférence aux langues anciennes et à celles de nos voisins. Qu'il faut parler François dans la société et dans les écoles de Philosophie; et Grec, Latin, Anglois, dans les chaires et sur le Théâtre: Que notre langue seroit celle de la vérité, si jamais elle revient sur la terre, et que la Grecque, la Latine, et les autres seroient les langues de la fable et du mensonge. Le François est fait pour instruire, éclairer, et convaincre; le Grec, le Latin, l'Italien, l'Anglois, pour persuader, émuouvoir, et tromper; parlez Grec, Latin, Italien au peuple, mais parlez François au sage." (*Œuvres de Diderot*, Tome II. pp. 70, 71. Amsterdam, 1772.)

These peculiar excellencies of the French language are ascribed, in part, by Diderot, to the study of the Aristotelian Philosophy. (*Ibid.* p. 7.) I do not well see what advantage France should, in this respect, have enjoyed over England; and since that philosophy fell into disrepute, it will scarcely be alleged that the habits of thinking cultivated by Locke's disciples have been less favourable to a logical rigour of expression than those of any contemporary sect of French metaphysicians.

A later French writer has, with far greater justice, acknowledged the important services rendered to the French language by the gentlemen of the Port Royal Society. "L'Ecole de Port Royal, féconde en penseurs, illustrée par les écrivains les plus purs, par les érudits les plus laborieux du siècle de Louis XIV. eût déjà rendu parmi nous un assez grand service à la philosophie par cela seul qu'elle a puissamment concouru à fixer notre langue, à lui donner ce caractère de précision, de clarté, d'exactitude, qui la rend si favorable aux opérations de l'esprit" (*Hist. Comparée, &c.* Tome II. p. 45.)

Mr Gibbon also has remarked, how much "the learned Society of Port Royal contributed to establish in France

ed; and the language has assumed a form more systematic, precise, and luminous. The transitions, too, in our best authors, have become more logical, and less dependent on fanciful or verbal associations. If by these means our native tongue has been rendered more unfit for some of the lighter species of writing, it has certainly gained immensely as an instrument of thought, and as a vehicle of knowledge. May I not also add, that the study of it has been greatly facilitated to foreigners; and that in proportion to its rejection of colloquial anomalies, more durable materials are supplied to the present generation for transmitting their intellectual acquisitions to posterity?

But granting the truth of these reflections, it may still be asked, what is the amount of the discoveries brought to light by the metaphysical speculations of the eighteenth century? Or rather, where are the principles to be found, of which it can be justly said, that they unite the suffrages, not of the *whole*, but even of the *majority* of our present philosophers? The question has been lately put and urged, with no common ability, by a foreign academician.

“The diversity of doctrines (says M. de Bonald) has increased, from age to age, with the number of masters, and with the progress of knowledge; and Europe, which at present possesses libraries filled with philosophical works, and which reckons up almost as many philosophers as writers; poor in the midst of so much riches, and uncertain with the aid of all its guides, which road it should follow; Europe, the centre and the focus of all the lights of the world, has yet its *philosophy* only in expectation.”¹

In proof of this assertion, the author appeals to the *Comparative History of Philosophical Systems relative to the Principles of Human Knowledge*, by M. de Gerando; and, after a variety of acute strictures on the contradictory systems there described, sums up his argument in the following words:

“Thus, the *Comparative History of Philosophical Systems* is nothing else than a *History of the Variations* of philosophical schools, leaving no other impression upon the reader than an insurmountable disgust at all philosophical researches; and a demonstrated conviction of the impossibility of raising an edifice on a soil so void of consistency, and so completely surrounded by the most frightful precipices. About what then are philosophers agreed? What single point have they placed beyond the reach of dispute? Plato and Aristotle inquired, What is science? What is knowledge? And we, so many ages

a taste for just reasoning, simplicity of style, and philosophical method.” The improvement in all these respects of our English writers, during the same period, is, in my opinion, much more remarkable.

¹ *Recherches Philosophiques*. &c. p. 2. Paris, 1818.

after these fathers of philosophy; we, so proud of the progress of human reason, still continue to repeat the same questions; vainly pursuing the same phantoms which the Greeks pursued two thousand years ago.”¹

In reply to this bold attack on the evidence of the moral sciences, it may suffice to recall to our recollection the state of physical science not more than two centuries ago. The argument of M. de Bonald against the former is, in fact, precisely the same with that ascribed by Xenophon to Socrates against those studies which have immortalized the names of Boyle and Newton; and which, in our own times, have revealed to us all the wonders of the modern chemistry. Whatever contradictions, therefore, may yet exist in our metaphysical doctrines (and of these contradictions many more than is commonly suspected will be found to be merely verbal), why should we despair of the success of future ages in tracing the laws of the intellectual world, which, though less obvious than those of the material world, are not less the natural and legitimate objects of human curiosity?

Nor is it at all wonderful that the beneficial effects of metaphysical habits of thinking should have been at first perceived in political economy, and some other sciences to which, on a superficial view, they may seem to have a very remote relation; and that the rise of the sap in the tree of knowledge should be indicated by the germs at the extremities of the branches before any visible change is discernible in the trunk. The sciences, whose improvement during the last century has been generally acknowledged, are those which are most open to common observation; while the changes which have taken place in the state of metaphysics, have attracted the notice of the few alone who take a deep interest in these abstract pursuits. The swelling of the buds, however, affords a sufficient proof that the roots are sound, and encourages the hope that the growth of the trunk, though more slow, will, in process of time, be equally conspicuous with that of the leaves and blossoms.

¹ *Recherches Philosophiques*, &c. pp. 58, 59.

On the other hand, may it not be asked, if the number of philosophical systems be greater than that of the sects which at present divide the Christian Church? The allusion here made to Bossuet's celebrated *History of the Variations*, shows plainly that the similarity of the two cases had not been overlooked by the ingenious writer; and that the only effectual remedy which, in his opinion, can be applied to either, is to subject once more the reason, both of philosophers and of divines, to the paramount authority of an infallible guide. The conclusion is such as might have been expected from a good Catholic; but I trust that, in this country, it is not likely to mislead many of my readers. Some recent conversions to Popery, however, which, in consequence of views similar to those of M. de Bonald, have taken place among the philosophers of Germany, afford a proof that, in the present political state of Europe, the danger of a temporary relapse into the superstitions of the Church of Rome, how slight soever, ought not to be regarded as altogether visionary. (See *Lectures on the History of Literature*, by Frederick Schlegel, Vol. II. pp. 65, 88, 89, 175, 187. English Translation, Edinburgh.)

I shall close this part of my Dissertation with remarking, that the practical influence of such speculations as those of Locke and of Bacon is to be traced only by comparing, on a large scale, the state of the human mind at distant periods. Both these philosophers appear to have been fully aware (and I know of no philosopher before them of whom the same thing can be said), that the progressive improvement of the species is to be expected less from the culture of the *reasoning powers*, strictly so called, than from the prevention, in early life, of those artificial impressions and associations, by means of which, when once rivetted by habit, the strongest reason may be held in perpetual bondage. These impressions and associations may be likened to the slender threads which fastened Gulliver to the earth; and they are to be overcome, not by a sudden exertion of intellectual force, but by the gradual effect of good education, in breaking them asunder one by one. Since the revival of letters, seconded by the invention of printing, and by the Protestant Reformation, this process has been incessantly going on, all over the Christian world; but it is chiefly in the course of the last century that the result has become visible to common observers. How many are the threads which, even in Catholic countries, have been broken by the writings of Locke! How many still remain to be broken, before the mind of man can recover that moral liberty which, at some future period, it seems destined to enjoy!

NOTES AND ILLUSTRATIONS.

NOTE (A.) p. 10.

It deserves to be remarked, as a circumstance which throws considerable light on the literary history of Scotland during the latter half of the eighteenth century, that, from time immemorial, a continued intercourse had been kept up between Scotland and the Continent. To all who were destined for the profession of law, an education either at a Dutch or French university was considered as almost essential. The case was nearly the same in the profession of physic; and, even among the Scottish clergy, I have conversed, in my youth, with some old men who had studied theology in Holland or in Germany. Of our smaller country gentlemen, resident on their own estates (an order of men which, from various causes, has now, alas! totally vanished), there was scarcely one who had not enjoyed the benefit of a university education; and very few of those who could afford the expence of foreign travel, who had not visited France and Italy. Lord Monboddo somewhere mentions, to the honour of his father, that he sold part of his estate to enable himself (his eldest son) to pursue his studies at the University of Groningen. The constant influx of information and of liberality from abroad, which was thus kept up in Scotland in consequence of the ancient habits and manners of the people, may help to account for the sudden burst of genius, which to a foreigner must seem to have sprung up in this country by a sort of enchantment, soon after the rebellion of 1745. The great step then made was in the art of English composition. In the mathematical sciences, where the graces of writing have no place, Scotland, in proportion to the number of its inhabitants, was never, from the time of Neper, left behind by any country in Europe; nor ought it to be forgotten, that the philosophy of Newton was publicly taught by David Gregory at Edinburgh and by his brother James Gregory at St Andrews, before it was able to supplant the vortices of Descartes in that very university of which Newton was a member.¹

¹ For this we have the authority of Whiston, the immediate successor of Sir Isaac Newton in the Lucasian Professorship at Cambridge; and of Dr Reid, who was a nephew of the two Gregories. "Mr Gregory had already caused several of his scholars to keep Acts, as we call them, upon several branches of the Newtonian Philosophy; while we at Cambridge, poor wretches, were ignominiously studying the fictitious hypothesis of the Cartesians. (Whiston's *Memoirs of his own Life*.)

"I have by me" (says Dr Reid) "a *Thesis* printed at Edinburgh, 1690, by James Gregory, who was at that time Professor of Philosophy at St Andrew's, containing twenty-five positions; the first three relating to logic, and the abuse of it in the Aristotelian and Cartesian philosophy. The remaining twenty-two positions are a compend of Newton's *Principia*. This *Thesis*, as was the custom at that time in the Scottish Universities, was to be defended in a public disputation, by the candidates, previous to their taking their degree."—(Hutton's *Mathematical Dictionary*.—*Supplement* by Dr Reid to the article *Gregory*.)

The case was similar in every other liberal pursuit, where an ignorance of the delicacies of the English tongue was not an insuperable bar to distinction. Even in the study of eloquence, as far as it was attainable in their own vernacular idiom, some of the Scottish pleaders, about the era when the two kingdoms were united, seem ambitiously, and not altogether unsuccessfully, to have formed themselves upon models, which, in modern times, it has been commonly supposed to be more safe to admire than to imitate.¹ Of the progress made in this part of the island in Metaphysical and Ethical Studies, at a period long prior to that which is commonly considered as the commencement of our literary history, I shall afterwards have occasion to speak. At present, I shall only observe, that it was in the Scottish universities that the philosophy of Locke, as well as that of Newton, was first adopted as a branch of academical education.

NOTE (B.) p. 14.

EXTRACT of a letter from M. Allamand to Mr Gibbon. (See Gibbon's *Miscellaneous Works*.)

“ Vous avez sans doute raison de dire que les propositions évidentes dont il s'agit, ne sont pas de simples idées, mais des jugemens. Mais ayez aussi la complaisance de reconnaître que M. Locke les alléguant en exemple d'idées qui passent pour innées, et qui ne le sont pas selon lui, s'il y a ici de la méprise, c'est lui qu'il faut relever la-dessus, et non pas moi, qui n'avois autre chose à faire qu'à réfuter sa manière de raisonner contre l'innéité de ces idées ou jugemens là. D'ailleurs, Monsieur, vous remarquerez, s'il vous plaît, que dans cette dispute il s'agit en effet, de savoir si certaines vérités évidentes et communes, et non pas seulement certaines idées simples, sont innées ou non. Ceux qui affirment, ne donnent guère pour exemple d'idées simples qui le soient, que celles de Dieu, de l'unité, et de l'existence; les autres exemples sont pris de propositions complètes, que vous appelez jugemens.

“ Mais, dites vous, y aura-t-il donc des jugemens innés? Le jugement est il autre chose qu'un acte de nos facultés intellectuelles dans la comparaison des idées? Le jugement sur les vérités évidentes, n'est il pas une simple vue de ces vérités là, un simple coup d'œil que l'esprit jette sur elles? J'accorde tout cela. *Et de grace, qu'est ce qu' idée? N'est ce pas vue, ou coup d'œil, si vous voulez?* Ceux qui définissent l'idée autrement, ne s'éloignent-ils pas visiblement du sens et de l'intention du mot? Dire que les idées sont les *espèces* des choses imprimées dans l'esprit, comme l'image de l'objet sensible est tracée dans l'œil, n'est ce pas jargonner plutôt que définir? Or c'est la faute, qu'ont fait tous les *metaphysiciens*, et quoique M. Locke l'ait bien sentie, il a mieux aimé se facher contre eux, et tirer contre les girouettes de la place, que s'appliquer à démêler ce galimatias. Que n'a-t-il dit, non seulement il n'y a point d'idées innées dans le sens de ces Messieurs; mais *il n'y a point d'idées du tout dans ce sens là; toute idée est un acte, une vue, un coup d'œil de l'esprit.* Dès-lors demander s'il y a des idées innées, c'est demander s'il y a certaines vérités si évidentes et si communes que tout esprit non stupide puisse naturellement, sans culture et sans maître, sans discussion, sans raisonnement, les reconnaître d'un coup d'œil, et souvent même sans s'apercevoir qu'on jette ce coup d'œil. L'affirmative me paroît incontestable, et selon moi, la question est vidée par là.

¹ See a splendid eulogium in the Latin language, by Sir George Mackenzie, on the most distinguished pleaders of his time at the Scottish Bar. Every allowance being made for the flattering touches of a friendly hand, his portraits can scarcely be supposed not to have borne a strong and characteristic resemblance to the originals from which they were copied.

“ Maintenant prenez garde, Monsieur, que cette manière d'entendre l'affaire, va au but des partisans des idées innées, tout comme la leur ; et par la même contredit M. Locke dans le sien. Car pourquoi voudroit on qu'il y a eu des idées innées ? C'est pour en opposer la certitude et l'evidence au doute universel des sceptiques, qui est ruiné d'un seul coup, s'il y a des vérités dont la vue soit nécessaire et naturelle à l'homme. Or vous sentez, Monsieur, que je puis leur dire cela dans ma façon d'expliquer la chose, tout aussi bien que les partisans ordinaires des idées innées dans la leur. Et voilà ce que semble incommoder un peu M. Locke, qui, sans se déclarer Pyrrhonien, laisse appercevoir un peu trop de foible pour le Pyrrhonisme, et a beaucoup contribué à le nourrir dans ce siècle. A force de vouloir marquer les bornes de nos connoissances, ce qui étoit fort nécessaire, il a quelquefois tout mis en bornes.”

NOTE (C.) p. 15.

“ A DECISIVE proof of this is afforded by the allusions to Locke's doctrines in the dramatic pieces then in possession of the French stage,” &c.

In a comedy of Destouches (entitled *La Fausse Agnès*), which must have been written long before the period in question,¹ the heroine, a lively and accomplished girl, supposed to be just arrived from Paris at her father's house in Poitou, is introduced as first assuming the appearance of imbecility, in order to get rid of a disagreeable lover ; and afterwards, as pleading her own cause in a mock trial before an absurd old president and two provincial ladies, to convince them that she is in reality not out of her senses. In the course of her argument on this subject, she endeavours to astonish her judges by an ironical display of her philosophical knowledge ; warning them of the extreme difficulty and nicety of the question upon which they are about to pronounce. “ Vous voulez juger de moi ! mais, pour juger sainement, il faut une grande étendue de connoissance ; encore est il bien douteux qu'il y en ait de certaines. Avant donc que vous entrepreniez de prononcer sur mon sujet, je demande préalablement que vous examiniez avec moi nos connoissances en general, les degrés de ces connoissances, leur étendue, leur réalité ; que nous convenions de ce que c'est que la vérité et si la vérité se trouve effectivement. Après quoi nous traiterons des propositions universelles, des maximes, des propositions frivoles, et de la foiblesse, ou de la solidité de nos lumières Quelque personnes tiennent pour vérité, que l'homme nait avec certains principes innés, certaines notions primitives, certains caractères que sont comme gravés dans son esprit, dès le premier instant de son existence. Pour moi, j'ai longtemps examiné ce sentiment, et j'entreprends de le combattre, de le refuter, de l'anéantir, si vous avez la patience de m'écouter.” I have transcribed but a part of this curious pleading ; but I presume more than enough to show, that every sentence, and almost every word of it, refers to Locke's doctrines. In the second and third sentences, the titles of the principal chapters in the fourth book of his *Essay* are exactly copied. It was impossible that such a scene should have produced the slightest comic effect, unless the book alluded to had been in very general circulation among the higher orders ; I might perhaps add, in much

¹ This little piece was first published in 1757, three years after the author's death, which took place in 1754, in the seventy-fourth year of his age. But we are told by D'Alembert, that from the age of sixty, he had renounced, from sentiments of piety, all thoughts of writing for the stage. (*Eloge de Destouches.*) This carries the date of all his dramatic works, at least as far back as 1740. As for Destouches' own familiarity with the writings of Locke, it is easily accounted for by his residence in England from 1717 to 1723, where he remained, for some time after the departure of Cardinal Dubois, as *Charge d'Affaires*. Voltaire did not visit England till 1727.

more general circulation than it ever obtained among that class of readers in England. At no period, certainly, since it was first published (such is the difference of national manners), could similar allusions have been made to it, or to any other work on so abstract a subject, with the slightest hope of success on the London stage. And yet D'Alembert pronounces *La Fausse Agnes* to be a piece, *pleine de mouvement et de gaieté*.

NOTE (D.) p. 18.

"DESCARTES asserted" (says a very zealous Lockist, M. de Voltaire), "that the soul, at its coming into the body, is informed with the whole series of metaphysical notions; knowing God, infinite space, possessing all abstract ideas; in a word, completely endued with the most sublime lights, which it unhappily forgets at its issuing from the womb."

"With regard to myself" (continues the same writer), "I am as little inclined as Locke could be, to fancy that, some weeks after I was conceived, I was a very learned soul; knowing at that time a thousand things which I forgot at my birth; and possessing, when in the womb (though to no manner of purpose), knowledge which I lost the instant I had occasion for it; and which I have never since been able to recover perfectly."—*Letters Concerning the English Nation*. Letter 13.

Whatever inferences may be deducible from some of Descartes's expressions, or from the comments on these expressions by some who assumed the title of Cartesians, I never can persuade myself, that the system of *innate ideas*, as conceived and adopted by him, was meant to give any sanction to the absurdities here treated by Voltaire with such just contempt. In no part of Descartes's works, as far as I have been able to discover, is the slightest ground given for this extraordinary account of his opinions. Nor was Descartes the first person who introduced this language. Long before the date of his works, it was in common use in England; and is to be found in a Poem of Sir John Davis, published four years before Descartes was born. (See Sect. XXVI. of *The Immortality of the Soul*.) The title of this section expressly asserts, That *there are innate ideas in the soul*.

In one of Descartes's letters, he enters into some explanations with respect to this part of his philosophy, which he complains had been very grossly misunderstood or misrepresented. To the following passage I have no doubt that Locke himself would have subscribed. It strikes myself as so very remarkable, that, in order to attract to it the attention of my readers, I shall submit it to their consideration in an English translation.

"When I said that the idea of God is innate in us, I never meant more than this, that Nature has endowed us with a faculty by which we may know God; but I have never either said or thought, that such ideas had an actual existence, or even that they were *species* distinct from the faculty of thinking. I will even go farther, and assert that nobody has kept at a greater distance than myself from all this trash of scholastic entities, insomuch that I could not help smiling when I read the numerous arguments which Regius has so industriously collected to show that infants have no actual knowledge of God while they remain in the womb. Although the idea of God is so imprinted on our minds, that every person has within himself the faculty of knowing him, it does not follow that there may not have been various individuals who have passed through life without ever making this idea a distinct object of apprehension; and, in truth, they who think they have an idea of a plurality of Gods, have no idea of God whatsoever." (Cartesii, *Epist.* Pars I. Epist. xcix.)

After reading this passage from Descartes, may I request of my readers to look back to the extracts in the beginning of this note, from Voltaire's letters? A remark of Montesquieu, occasioned

by some strictures hazarded by this lively but very superficial philosopher on the *Spirit of Laws*, is more peculiarly applicable to him when he ventures to pronounce judgment on metaphysical writers: "Quant à Voltaire, il a trop d'esprit pour m'entendre; tous les livres qu'il lit, il les fait, après quoi il approuve ou critique ce qu'il a fait." (*Lettre à M. l'Abbé de Guasco.*) The remark is applicable to other critics as well as to Voltaire.

The prevailing misapprehensions with respect to this, and some other principles of the Cartesian metaphysics, can only be accounted for by supposing, that the opinions of Descartes have been more frequently judged of from the glosses of his followers, than from his own works. It seems to have never been sufficiently known to his adversaries, either in France or in England, that, after his philosophy had become fashionable in Holland, a number of Dutch divines, whose opinions differed very widely from his, found it convenient to shelter their own errors under his established name; and that some of them went so far as to avail themselves of his authority in propagating tenets directly opposite to his declared sentiments. Hence a distinction of the *Cartesians* into the *genuine* and the *pseudo-Cartesians*; and hence an inconsistency in their representations of the metaphysical ideas of their master, which can only be cleared up by a reference (seldom thought of) to his own very concise and perspicuous text. (*Fabricii Bib. Gr. lib. iii. cap. vi. p. 183. Heinecc. El. Hist. Phil. § cx.*)

Many of the objections commonly urged against the *innate ideas* of Descartes are much more applicable to the *innate ideas* of Leibnitz, whose language concerning them is infinitely more hypothetical and unphilosophical; and sometimes approaches nearly to the enthusiastic theology of Plato and of Cudworth. Nothing in the works of Descartes bears any resemblance, in point of extravagance, to what follows: "Pulcherrima multa sunt Platonis dogmata, esse in divina mente mundum intelligibilem, quem ego quoque vocare soleo regionem idearum; objectum sapientiæ esse τὰ ὀντα; ὀντα, substantias nempe simplices, quæ a me *monades* appellantur, et semel existentes semper perstant, πρῶτα διτινα τῆς ζωῆς, id est Deum et Animas, et harum polissimas mentes, producta a Deo simulacra divinitatis. Porro quævis mens, ut recte Plotinus, quendam in se mundum intelligibilem continet, imo mea sententia et hunc ipsum sensibilem sibi representat. Sunt in nobis *semina eorum*, quæ discimus, ideæ nempe, et quæ inde nascuntur, æternæ veritates. Longe ergo præferendæ sunt Platonis *notitiæ innatæ*, quas *reminiscentiæ* nomine velavit, tabulæ raræ Aristotelis et Lockii, aliorumque recentiorum, qui *ἐντελεῖαι* philosophantur." (*Leib. Opera*, Tom. II. p. 223.)

Wild and visionary, however, as the foregoing propositions are, if the names of Gassendi and of Hobbes had been substituted instead of those of Aristotle and of Locke, I should have been disposed to subscribe implicitly to the judgment pronounced in the concluding sentence. The metaphysics of Plato, along with a considerable alloy of poetical fiction, has at least the merit of containing a large admixture of important and of ennobling truth; while that of Gassendi and of Hobbes, beside its inconsistency with facts attested, every moment, by our own consciousness, tends directly to level the rational faculties of man with the instincts of the brutes.

In the *Acta Eruditorum* for the year 1684, Leibnitz observes, that "in the case of things which we have never thought of, the *innate ideas* in our minds may be compared to the figure of Hercules in a block of marble." This seems to me to prove, that the difference between him and Locke was rather in appearance than in reality; and that, although he called those ideas *innate* which Locke was at pains to trace to sensation or to reflection, he would have readily granted, that our first knowledge of their existence was coeval with the first impressions made on our senses by external objects. That this was also the opinion of Descartes is still more evident; notwithstanding the ludicrous point of view in which Voltaire has attempted to exhibit this part of his system.

NOTE (E.) p. 19.

MR LOCKE seems to have considered this use of the word *reflection* as peculiar to himself; but it is perfectly analogous to the *κίνησις κυκλῆταις* of the Greek philosophers, and to various expressions which occur in the works of John Smith of Cambridge, and of Dr Cudworth. We find it in a *Poem on the Immortality of the Soul*, by Sir John Davis, Attorney-General to Queen Elizabeth. and probably it is to be met with in English publications of a still earlier date.

All things without which round about we see,
 We seek to know, and have wherewith to do;
 But that whereby we reason, live, and be,
 Within ourselves we strangers are thereto.

Is it because the mind is like the eye,
 Thro' which it gathers knowledge by degrees;
 Whose rays *reflect* not, but spread outwardly;
 Not seeing itself, when other things it sees?

No, doubtless; for the mind can backward cast
 Upon herself her understanding light;
 But she is so corrupt, and so defac'd,
 As her own image doth herself affright.

As is the fable of the Lady fair,
 Which for her lust was turn'd into a cow;
 When thirsty, to a stream she did repair,
 And saw herself transform'd, she wist not how:

At first she startles, then she stands amaz'd;
 At last with terror she from hence doth fly,
 And loathes the wat'ry glass wherein she gaz'd,
 And shuns it still, altho' for thirst she die.

For even at first *reflection* she espies
 Such strange chimeras, and such monsters there;
 Such toys, such anticks, and such vanities,
 As she rather shrinks for shame and fear.

I have quoted these verses, chiefly because I think it not improbable that they may have suggested to Gray the following very happy allusion in his fine Fragment *De Principiis Cogitandi*:

Qualis Hamadryadum quondam si forte sororum
 Una, novos peragrans saltus, et septis rursus
 (Atque illum in viridi sundet percurrere ripa
 Fons pura quies, et opaci frigida umbra);
 Dum promissa latucae speculi de margine pendet,
 Mirata est subitam venienti occurrere Nympham
 Max eodem, quos ipsa, artus, eadem ora gerentem
 Unà inferre gradus, unà succedere sylvas
 Aspicit alludens; necque agnoscit in undis:
 Sic sensu interno rerum simulacra suarum
 Mens cœt, et proprios observat consæta vultus.

NOTE (F.) p. 37.

THE chief attacks made in England on Locke's *Essay*, during his own lifetime, were by Edward Stillingfleet, Bishop of Worcester; John Norris, Rector of Bemerton; Henry Lee, B. D.; and the Reverend Mr. Lewis (author of a *Discourse concerning the Nature of Man*). Of these four writers, the first is the only one whose objections to Locke are now at all remembered in the learned world; and for this distinction, Stillingfleet is solely indebted (I speak of him here merely as a metaphysician, for in some other departments of study, his merits are universally admitted) to the particular notice which Lock has condescended to take of him, in the Notes incorporated with the later editions of his *Essay*. The only circumstance which renders these Notes worthy of preservation, is the record they furnish of Locke's forbearance and courtesy, in managing a controversy carried on, upon the other side, with so much captiousness and asperity. An Irish Bishop, in a letter on this subject to Mr. Molyneux, writes thus: "I read Mr Locke's letter to the Bishop of Worcester with great satisfaction, and am wholly of your opinion, that he has fairly laid the great bishop on his back, but it is with so much gentleness, as if he were afraid not only of hurting him, but even of spoiling or troubling his clothes."

The work of Lee is entitled *Axi-scepticism*, or Notes upon each Chapter of Mr Locke's *Essay concerning Human Understanding*, with an explanation of all the particulars of which he treats, and in the same order. By Henry Lee, B. D. formerly Fellow of Emanuel College in Cambridge, now Rector of Tichmarsh in Northamptonshire. London, 1702, in folio.

The strictures of this author, which are often acute and sometimes just, are marked throughout with a fairness and candour rarely to be met with in controversial writers. It will appear remarkable to modern critics that he lays particular stress upon the charms of Locke's style,* among the other excellencies which had conspired to recommend his work to public favour. "The celebrated author of the *Essay on Human Understanding* has all the advantages desirable to recommend it to the inquisitive genius of this age, an avowed pretence to new methods of discovering truth and improving learning; an unusual coherence in the several parts of his scheme; a singular clearness in his reasonings; and above all, a natural elegance of style; an unaffected beauty in his expressions; a just proportion and tuneful cadence in all his periods." (See the *Epistle Dedicatory*)

NOTE (G.) p. 41.

FOR the information of some of my readers, it may be proper to observe, that the word *influi* came to be employed to denote the action of body and soul on each other, in consequence of a prevailing theory which supposed that this action was carried on by something intermediate (whether material or immaterial was not positively decided) flowing from the one substance to the other. It is in this sense that the word is understood by Leibnitz, when he states as an insurmountable objection to the theory of *influi*, that "it is impossible to conceive either material particles or immaterial qualities to pass from body to mind, or from mind to body."

Instead of the term *influi*, that of *influence* came gradually to be substituted by our English

* Of this person, who was a most ingenious and original thinker, I shall have occasion afterwards to speak.

writers; but the two words were originally synonymous, and were used indiscriminately as late as the time of Sir Matthew Hale. (See his *Primitive Origination of Mankind*.)

In Johnson's *Dictionary*, the primitive and radical meaning assigned to the word *influence* (which he considers as of French extraction) is "the power of the celestial aspects operating upon terrestrial bodies and affairs;" and in the *Encyclopædia* of Chambers, it is defined to be "a quality supposed to flow from the bodies of the stars, either with their heat or light, to which astrologers vainly attribute all the events which happen on the earth." To this astrological use of the word Milton had plainly a reference in that fine expression of his *L'Allegro*,

"Store of ladies whose bright eyes

"Rain influence."¹

It is a circumstance worthy of notice, that a word thus originating in the dreams of astrologers and schoolmen, should now, in our language, be appropriated almost exclusively to politics. "Thus" (says Blackstone) "are the electors of one branch of the legislature secured from any undue influence from either of the other two, and from all external violence and compulsion; but the greatest danger is that in which themselves co-operate by the infamous practice of bribery and corruption." And again, "The crown has gradually and imperceptibly gained almost as much in influence as it has lost in prerogative."

In all these cases, there will be found at bottom one common idea, the existence of some secret and mysterious connection between two things, of which connection it is conceived to be impossible or unwise to trace what Bacon calls the *latens processus*.

NOTE (H.) p. 43.

AFTER these quotations from Locke, added to those which I have already produced from the same work, the reader may judge of the injustice done to him by Leibnitz, in the first sentence of his correspondence with Clarke.

"Il semble que la religion naturelle même s'affoiblit extrêmement. Plusieurs font les ames corporelles; d'autres font Dieu lui-même corporel.

"M. Locke et ses sectateurs, doutent au moins, si les ames ne sont matérielles, et naturellement périssables."

Dr Clarke, in his reply to this charge, admits that "some parts of Locke's writings may justly be suspected as intimating his doubts whether the soul be immaterial or no, but herein (he adds) he has been followed only by some Materialists, enemies of the mathematical principles of philosophy; and who approve little or nothing in Mr Locke's writings, but his errors."

To those who have studied with care the whole writings of Locke, the errors here alluded to will appear in a very venial light when compared with the general spirit of his philosophy. Nor can I forbear to remark farther on this occasion, that supposing Locke's doubts concerning the immateriality of the soul to have been as real as Clarke seems to have suspected, this very circumstance would only reflect the greater lustre on the soundness of his logical views concerning the proper method of studying the mind;—in the prosecution of which study, he has adhered much more systematically

¹ The explanation of the word *Influence*, given in the *Dictionary* of the French Academy, accords perfectly with the tenor of the above remarks. "Verbe qui, suivant les Astrologues, découle des astres sur les corps sublunaires."

than either Descartes or Leibnitz, to the exercises of *reflection*, as the sole medium for ascertaining the internal phenomena; describing, at the same time, these phenomena in the simplest and most rigorous terms which our language affords, and avoiding, in a far greater degree than any of his predecessors, any attempt to explain them by analogies borrowed from the perceptions of the external senses.

I before observed, that Leibnitz greatly underrated Locke as a metaphysician. It is with regret I have now to mention, that Locke has by no means done justice to the splendid talents and matchless erudition of Leibnitz. In a letter to his friend Mr Molyneux, dated in 1697, he expresses himself thus: "I see you and I agree pretty well concerning Mr Leibnitz; and this sort of fiddling makes me hardly avoid thinking, that he is not that very great man as has been talked of him." And in another letter, written in the same year to the same correspondent, after referring to one of Leibnitz's Memoirs in the *Acta Eruditorum* (*De primæ Philosophiæ Emendatione*), he adds, "From whence I only draw this inference, that even great parts will not master any subject without great thinking, and that even the largest minds have but narrow swallows."

Let me add, that in my quotations from English writers, I adhere scrupulously to their own phraseology, in order to bring under the eye of my readers, specimens of English composition at different periods of our history. I must request their attention to this circumstance, as some expressions in the former part of this Dissertation, which have been censured as Scotticisms, occur in Extracts from authors who, in all probability, never visited this side of the Tweed.

NOTE (I.) p. 51.

AFTER studying, with all possible diligence, what Leibnitz has said of his *monads* in different parts of his works, I find myself quite incompetent to annex any precise idea to the word as he has employed it. I shall, therefore, aim at nothing more in this note, but to collect, into as small a compass as I can, some of his most intelligible attempts to explain its meaning.

"A substance is a thing capable of action. It is simple or compounded. A simple substance is that which has no parts. A compound substance is an aggregate of simple substances or of *monads*.

"Compounded substances, or bodies, are multitudes. Simple substances, lives, souls, spirits, are units.¹ Such simple substances must exist every where; for without simple substances there could be no compounded ones. All nature therefore is full of life." (Tom. II. p. 32.)

"*Monads*, having no parts, are neither extended, figured, nor divisible. They are the real atoms of nature, or, in other words, the elements of things." (Tom. II. p. 20.)

(It must not, however, be imagined, that the *monads* of Leibnitz have any resemblance to what are commonly called *atoms* by philosophers. On the contrary, he says expressly, that "*monads* are not atoms of matter, but atoms of substances;—real units, which are the first principles in the composition of things, and the last elements in the analysis of substances;—of which principles or elements, what we call *bodies* are only the *phenomena*."—(Tom. II. pp. 53. 325.)

In another passage we are told, that "a *monad* is not a *material* but a *formal* atom, it being impossible for a thing to be at once material, and possessed of a real unity and indivisibility. It is necessary, therefore" (says Leibnitz), "to revive the obsolete doctrine of *substantial forms* (the es-

¹ "Les substances simples, les vies, les âmes, les esprits, sont des unités."

sence of which consists in force), separating it, however, from the various abuses to which it is liable."—(*Ibid.* p. 59.)

"Every monad is a living mirror, representing the universe, according to its particular point of view, and subject to as regular laws as the universe itself."

"Every monad, with a particular body, makes a living substance."

"The knowledge of every soul (*ame*) extends to infinity, and to all things; but this knowledge is confused. As a person walking on the margin of the sea, and listening to its roar, hears the noise of each individual wave of which the whole noise is made up, but without being able to distinguish one sound from another, in like manner, our confused perceptions are the result of the impressions made upon us by the whole universe. The case (*he* adds) is the same with each monad."

"As for the reasonable soul or mind (*l'esprit*), there is something in it more than in the monads, or even than in those souls which are simple. It is not only a mirror of the universe of created things, but an image of the Deity. Such minds are capable of reflected acts, and of conceiving what is meant by the words *I, substance, monad, soul, mind*; in a word, of conceiving things and truths unconnected with matter; and it is this which renders us capable of science and of demonstrative reasoning.

"What becomes of these souls or forms, on the death of the animal? There is no alternative (replies Leibnitz) but to conclude, that not only the soul is preserved, but that the animal also with its organical machine continues to exist, although the destruction of its grosser parts has reduced it to a smallness as invisible to our eyes as it was before the moment of conception. Thus neither animals nor souls perish at death; nor is there such a thing as death, if that word be understood with rigorous and metaphysical accuracy. The soul never quits completely the body with which it is united, nor does it pass from one body into another with which it had no connection before, a *metamorphosis* takes place, but there is no *metempsychosis*."—(Tom. II. pp. 51, 52.)

On this part of the Leibnitzian system, D'Alembert remarks, that it proves nothing more than that the author had perceived better than any of his predecessors, the impossibility of forming a distinct idea of the nature of matter; a subject, however (D'Alembert adds), on which the theory of the monads does not seem calculated to throw much light. I would rather say (without altogether denying the justness of D'Alembert's criticism), that this theory took its rise from the author's vain desire to explain the nature of forces; in consequence of which he suffers himself perpetually to be led astray from those sensible effects which are exclusively the proper objects of physics, into conjectures concerning their efficient causes, which are altogether placed beyond the reach of our research.

NOTE (K.) p. 55.

THE metaphysical argument advanced by the Leibnitzians in proof of the law of continuity has never appeared to me to be satisfactory. "If a body at rest (it has been said) begins, *per saltum*, to move with any finite velocity, then this body must be at the same indivisible instant in two different states, that of rest and of motion, which is impossible."¹

¹ "Si toto tempore (says Father Roscovich, speaking of the Law of Continuity in the Collision of Bodies) ante contactum subsequentis corporis superficies antecedens habuit 12 gradus velocitatis, et sequenti 9, saltu facto momentaneo ipso initio contactus; in

As this reasoning, though it relates to a *physical fact*, is itself wholly of a *metaphysical* nature, and as the inference deduced from it has been generalized into a *LAW*, supposed to extend to all the various branches of human knowledge, it is not altogether foreign to our present subject briefly to consider how far it is demonstratively conclusive, in this simplest of all its possible applications.

On the above argument, then, I would remark, 1. That the ideas both of *rest* and of *motion*, as well as the more general idea conveyed by the word *state*, all of them necessarily involve the idea of *time* or *duration*; and, consequently, a body cannot be said to be in a *state* either of rest or of motion, at an *indivisible instant*. Whether the body be supposed (as in the case of motion) to *change* its place from one instant to another; or to *continue* (as in that of rest) for an instant in the same place, the idea of some finite portion of time will, on the slightest reflection, be found to enter as an essential element into our conception of the physical fact.

2. Although it certainly would imply a contradiction to suppose a body to be in two different *states* at the same instant, there does not appear to be any inconsistency in asserting that an indivisible instant may form the limit between a state of rest and a state of motion. Suppose one half of this page to be painted white, and the other black, it might, I apprehend, be said, with the most rigorous propriety, that the transition from the one colour to the other was made *per saltum*; nor do I think it would be regarded as a valid objection to this phraseology, to represent it as one of its implied consequences, that the mathematical line which forms their common limit, must at once be both black and white. It seems to me quite impossible to elude the force of this reasoning, without having recourse to the existence of something intermediate between *rest* and *motion*, which does not partake of the nature of either.

Is it conceivable that a body can exist in any *state* which does not fall under one or other of the two predicaments, rest or motion? If this question should be answered in the negative, will it not follow that the transition from one of these *states* to the other must, of necessity, be made *per saltum*, and must consequently violate the supposed law of continuity? Indeed, if such a law existed, how could a body at rest *begin* to move, or a body in motion come to a state of rest?

But farther, when it is said that "it is impossible for a body to have its state changed from motion to rest, or from rest to motion, without passing through all the intermediate degrees of velocity," what are we to understand by the *intermediate degrees of velocity between rest and motion*? Is not every velocity, how small soever, a *finite velocity*; and does it not differ as essentially from a state of rest, as the velocity of light?

It is observed by Mr Playfair (*Second Dissertation*, Part I. p. 70), that Galileo was the first who maintained the existence of the *law of continuity*, and who made use of it as a principle in his reasonings on the phenomena of motion. Mr Playfair, however, with his usual discrimination and correctness, ranks this among the *mechanical* discoveries of Galileo. Indeed, it does not appear that it was at all regarded by Galileo (as it avowedly was by Leibnitz) in the light of a metaphysical

ipse momentis ea tempora dirimente debuisse habere et 12 et 9 simul, quod est absurdum. Duae enim velocitates simul habere corpus non potest."—*Theoria Phil. Nat.* &c.

Boscovich, however, it is to be observed, admits the existence of the Law of Continuity in the phenomena of Motion alone (§ 143), and rejects it altogether in things co-existent with each other (§ 142). In other cases, he says, Nature does not observe the Law of Continuity with mathematical accuracy, but only *affects it*; by which expression he seems to mean, that, where she is guilty of a *salutis*, she aims at making it as moderate as possible. The expression is certainly deficient in metaphysical precision; but it is not unworthy of attention, inasmuch as it affords a proof, that Boscovich did not (with the Leibnitzians) conceive Nature, or the Author of Nature, as obeying an *irreversible necessity* in observing or not observing the Law of Continuity.

and necessary law, which could not by any possibility be violated in any of the phenomena of motion. It was probably first suggested to him by the diagram which he employed to demonstrate, or rather to illustrate, the uniformly accelerated motion of falling bodies;¹ and the numberless and beautiful exemplifications of the same law which occur in pure geometry, sufficiently account for the disposition which so many Mathematicians have shown to extend it to all those branches of physics which admit of a mathematical consideration.

My late illustrious friend, who, to his many other great and amiable qualities, added the most perfect fairness and candour in his inquiries after truth, has, in the posthumous fragment which has already appeared in this *Supplement*, expressed himself with considerably greater scepticism concerning the law of continuity, than in his *Outlines of Natural Philosophy*. In that work he pronounced the metaphysical argument, employed by Leibnitz to prove its necessity, "to be conclusive." (Sect. VI. § 99, b.) In the second part of his *Dissertation* (p. 34), he writes thus on the same subject:

"Leibnitz considered this principle as known *a priori*, because, if any *saltus* were to take place, that is, if any change were to happen without the intervention of time, the thing changed must be in two different conditions at the same individual instant, which is obviously impossible. Whether this reasoning be quite satisfactory or no, the conformity of the law to the facts generally observed cannot but entitle it to great authority in judging of the explanations and theories of natural phenomena."

The phrase, *Law of Continuity*, occurs repeatedly in the course of the correspondence between Leibnitz and John Bernouilli, and appears to have been first used by Leibnitz himself. The following passage contains some interesting particulars concerning the history of this law: "*Lex Continuitatis*, cum usque adeo sit rationi et naturæ consentanea, et usum habeat tam late patentem, mirum tamen est eam a nemine (quantum recorder) antea adhibitam fuisse. Mentionem ejus aliquam feceram olim in *Novellis Reipublicæ Literariæ* (Juillet 1687, p. 744), occasione collationculæ cum Malebranchio, qui ideo meis considerationibus persuasus, suam de legibus motus in *Inquisitione Veritatis* expositam doctrinam postea mutavit; quod brevi libello edito testatus est, in quo ingenue occasionem mutationis exponit. Sed tamen paullo promptior, quam par erat, fuit in novis legibus constituendis in eodem libello, antequam mecum communicasset; nec tantum in veritatem, sed etiam in illam ipsam *Legem Continuitatis*, etsi minus aperte, denuo tamen impegit; quod nolui viro optimo objicere, ne viderer ejus existimationi detrudere velle.—*Epist.* Leibnit. ad Joh. Bernouilli, 1697.

From one of John Bernouilli's letters to Leibnitz, it would appear that he had himself a conviction of the truth of this law, before he had any communication with Leibnitz upon the subject.

"Placet tuum criterium pro examinandis regulis motuum, quod *legem continuitatis* vocas; est enim per se evidens, et velut a natura nobis inditum, quod evanescente inæqualitate hypothesisum, evanescere quoque debeant inæqualitates eventuum. Hinc multoties non satis mirari potui, qui

¹ Descartes seems, from his correspondence with Mersenne, to have been much puzzled with Galileo's reasonings concerning the descent of falling bodies; and in alluding to it, has, on different occasions, expressed himself with an indecision and inconsistency of which few instances occur in his works. (Vide *Corteati Epist.* Pars II. Epist. xxxiv. xxxv. xxxvii. xci.) His doubts on this point will appear less surprising, if compared with a passage in the article *Mécanique* in D'Alembert's *Elémens de Philosophie*. "Tous les philosophes paroissent convenir, que la vitesse avec laquelle les corps qui tombent commencent à se mouvoir est absolument nulle, &c. &c." (See his *Mélanges*, Tom. IV. p. 219, 220.)

fieri potuerit, ut tam incongruas tam absonas, et tam manifeste inter se pugnantes regulas excepta sola prima, potuerit condere Cartesius, vir alias summi ingenii. Mihi videtur vel ab infante falsitatem illarum parari posse, ea quod ubique saltus ille, naturæ adeo inimicus, manifeste nimis elucet." (*Epist. Bernouilli ad Leib.* 1696. Vide Leibnitzii et Jo. Bernouilli *Comm. Epist.* 2 vols. 4to, Lausannæ et Genève, 1746.)

NOTE (L.) p. 56.

MAIS il restoit encore la plus grande question, de ce que ces âmes ou ces formes deviennent par la mort de l'animal, ou par la destruction de l'individu de la substance organisé. Et c'est ce qui embarrasse le plus; d'autant qu'il paroît peu raisonnable que les âmes restent inutilement dans un chaos de matière confuse. Cela m'a fait juger enfin qu'il n'y avoit qu'un seul parti raisonnable à prendre; et c'est celui de la conservation non seulement de l'âme, mais encore de l'animal même, et de la machine organique; quoique la destruction des parties grossières l'ait réduit à une petitesse qui n'échappe pas moins à nos sens que celle ou il étoit avant que de naître. (*Leib. Op.* Tom. II. p. 51.)

... Des personnes fort exactes aux expériences se sont déjà aperçues de notre tems,¹ qu'on peut douter, si jamais un animal tout à fait nouveau est produit, et si les animaux tout en vie ne sont déjà en petit avant la conception dans les semences aussi bien que les plantes. Cette doctrine étant posée, il sera raisonnable de juger, que ce qui ne commence pas de vivre ne cesse pas de vivre non plus; et que la mort, comme la génération, n'est que la transformation du même animal qui est tantôt augmenté, et tantôt diminué. (*Ibid.* pp. 42, 43.)

... Et puisqu'ainsi il n'y a point de première naissance ni de génération entièrement nouvelle de l'animal, il s'ensuit qu'il n'y en aura point d'extinction finale, ni de mort entière prise à la rigueur métaphysique; et que, par conséquent, au lieu de la transmigration des âmes, il n'y a qu'une transformation d'un même animal, selon que les organes sont pliés différemment, et plus ou moins développés. (*Ibid.* p. 52.)

Quant à la Métempsychose, je crois que l'ordre ne l'admet point; il veut que tout soit explicable distinctement, et que rien ne se fasse par saut. Mais le passage de l'âme d'un corps dans l'autre seroit un saut étrange et inexplicable. Il se fait toujours dans l'animal ce qui se fait présentement: C'est que le corps est dans un changement continu, comme un fleuve, et ce que nous appelons génération ou mort, n'est qu'un changement plus grand et plus prompt qu'à l'ordinaire, tel que seroit le saut ou la cataracte d'une rivière. Mais ces sauts ne sont pas absolus et tels que je desapprouve; comme seroit celui d'un corps qui iroit d'un lieu à un autre sans passer par le milieu. Et de tels sauts ne sont pas seulement défendus dans les mouvemens, mais encore dans tout ordre des choses ou des vérités.—The sentences which follow afford a proof of what I have elsewhere remarked, how much the mind of Leibnitz was misled, in the whole of this metaphysical theory, by habits of thinking formed in early life, amidst the hypothetical abstractions of pure geometry; a prejudice (or idol of the mathematical den) to which the most important errors of his philosophy might, without much difficulty, be traced.—“Or comme dans une ligne de géométrie il y a certains points distingués, qu'on appelle sommets, points d'inflexion, points de rebroussement, ou autrement; et comme il y en a des lignes qui en ont une infinité, c'est ainsi qu'il faut concevoir

¹ The experiments here referred to are the observations of Swammerdam, Malpighi, and Leuwenhoeck.

dans la vie d'un animal ou d'une personne les tems d'un changement extraordinaire, qui ne laissent pas d'être dans la règle générale; de même que les points distingués dans la courbe se peuvent déterminer par sa nature générale ou son équation. "On peut toujours dire d'un animal c'est tout comme ici, la différence n'est que de plus ou moins." (Tom. V. p. 18.)

NOTE (M.) p. 60.

THE praise which I have bestowed on this Memoir renders it necessary for me to take some notice of a very exceptionable proposition which is laid down in the first paragraph, as a fundamental maxim,—that "all proper names were at first Appellatives;" a proposition so completely at variance with the commonly received opinions among later philosophers, that it seems an object of some curiosity to inquire, how far it is entitled to plead in its favour the authority of Leibnitz. Since the writings of Condillac and of Smith, it has, so far as I know, been universally acknowledged, that, if there be any one truth in the *Theoretical History of Language*, which we are entitled to assume as an incontrovertible fact, it is the direct contrary of the above proposition. In deed, to assert that all proper names were at first appellative, would appear to be nearly an absurdity of the same kind as to maintain, that *classes* of objects existed before *individual* objects had been brought into being.

When Leibnitz, however, comes to explain his idea more fully, we find it to be something very different from what his words literally imply; and to amount only to the trite and indisputable observation, That, in simple and primitive languages, all proper names (such as the names of persons, mountains, places of residence, &c.) are descriptive or significant of certain prominent and characteristic features, distinguishing them from other objects of the same class,—a fact, of which a large proportion of the surnames still in use all over Europe, as well as the names of mountains, villages, and rivers, when traced to their primitive roots, afford numerous and well known exemplifications.

Not that the proposition, even when thus explained, can be assumed as a general maxim. It holds, indeed, in many cases, as the Celtic and the Saxon languages abundantly testify in our own island; but it is true only under certain limitations, and it is perfectly consistent with the doctrine delivered on this subject by the greater part of philologists for the last fifty years.

In the history of language, nothing is more remarkable, than the aversion of men to coin words out of unmeaning and arbitrary sounds; and their eagerness to avail themselves of the stores already in their possession, in order to give utterance to their thoughts on the new topics which the gradual extension of their experience is continually bringing within the circle of their knowledge. Hence metaphors, and other figures of speech; and hence the various changes which words undergo, in the way of amplification, diminution, composition, and the other transformations of elementary terms which fall under the notice of the etymologist. Were it not, indeed, for this strong and universal bias of our nature, the vocabulary of every language would, in process of time, become so extensive and unwieldy, as to render the acquisition of one's mother tongue a task of immense difficulty; and the acquisition of a dead or foreign tongue next to impossible. It is needless to observe, how immensely these tasks are facilitated by that etymological system which runs, more or less, through every language; and which everywhere proceeds on certain analogical principles, which it is the business of the practical grammarian to reduce to general rules, for the sake of those who wish to speak or to write it with correctness.

In attempting thus to trace backwards the steps of the mind towards the commencement of its progress, it is evident, that we must at last arrive at a set of elementary and primitive roots, of which no account can be given, but the arbitrary choice of those who first happened to employ them. It is to this *first* stage in the infancy of language, that Mr Smith's remarks obviously relate; whereas the proposition of Leibnitz, which gave occasion to this note, as obviously relates to its subsequent stages, when the language is beginning to assume somewhat of a regular form, by compositions and other modifications of the materials previously collected.

From these slight hints it may be inferred, 1st, That the proposition of Leibnitz, although it may seem, from the very inaccurate and equivocal terms in which it is expressed, to stand in direct opposition to the doctrine of Smith, was really meant by the author to state a fact totally unconnected with the question under Smith's consideration. 2dly, That even in the sense in which it was understood by the author, it fails entirely, when extended to that *first* stage in the infancy of language, to which the introductory paragraphs in Mr Smith's discourse are exclusively confined.

NOTE (N.) p. 62.

“ JE viens de recevoir une lettre d'un Prince Regnant de l'Empire, ou S. A. me marque avoir vu deux fois ce printems à la dernière foire de Leipsig et examiné avec soin, un chien qui parle. Ce chien a prononcé distinctement plus de trente mots, repondant même assez à propos à son maître : il a aussi prononcé tout l'alphabet excepté les lettres, m, n, x.” (Leib. Opera. Tom. V. p. 72.)

Thus far the fact rests upon the authority of the German prince alone. But from a passage in the *History of the Academy of Sciences*, for the year 1706, it appears that Leibnitz had himself seen and heard the dog. What follows is transcribed from a report of the Academy upon a letter from Leibnitz to the Abbé de St Pierre, giving the details of this extraordinary occurrence.

“ Sans un garant tel que M. Leibnitz, témoin oculaire, nous n'aurions pas la hardiesse de rapporter, qu'auprès de Zeitz dans la Misnie, il y a un chien qui parle. C'est un chien de Paysan, d'une figure des plus communes, et de grandeur médiocre. Un jeune enfant lui entendit pousser quelques sons qu'il crut ressembler à des mots Allemands, et sur cela se mit en tête de lui apprendre à parler. Le maître, qui n'avoit rien de mieux à faire, n'y épargna pas le tems ni ses peines, et heureusement le disciple avoit des dispositions qu'il eut été difficile de trouver dans un autre. Enfin, au bout de quelques années, le chien sut prononcer environ une trentaine de mots : de ce nombre sont *The, Caffé, Chocolat, Assemblée*, mots François, qui ont passé dans l'Allemand tels qu'ils sont. Il est à remarquer, que le chien avoit bien trois ans quand il fut mis à l'école. Il ne parle que par écho, c'est à dire, après que son maître a prononcé un mot; et il semble, qu'il ne repète que par force et malgré lui, quoiqu'on ne le maltraite pas. Encore une fois, M. Leibnitz l'a vu et entendu.”

(Exposé d'une lettre de M. Leibnitz à l'Abbé de St Pierre sur un chien qui parle.) “ Cet exposé de la lettre de M. Leibnitz se trouve dans l'Histoire de l'Académie des Sciences, Année 1706. Ce sont les Auteurs de l'Histoire de l'Académie qui parlent.” (Leib. Opera, Vol. II. p. 180. P. II.)

May not all these circumstances of the above story be accounted for, by supposing the master of the dog to have possessed that peculiar species of imitative power which is called *Ventriloquism*? Mathews, I have no doubt, would find little difficulty in managing such a deception, so as to impose on the senses of any person who had never before witnessed any exhibition of the same kind.

NOTE (O.) p. 62.

WHEN I speak in favourable terms of the *Philosophical Spirit*, I hope none of my readers will confound it with the spirit of that false philosophy, which, by unhinging every rational principle of belief, seldom fails to unite in the same characters the extremes of scepticism and of credulity. It is a very remarkable fact, that the same period of the eighteenth century, and the same part of Europe which were most distinguished by the triumphs of Atheism and Materialism, were also distinguished by a greater number of visionaries and impostors than had ever appeared before, since the revival of letters. Nor were these follies confined to persons of little education. They extended to men of the highest rank, and to many individuals of distinguished talents. Of this the most satisfactory proofs might be produced; but I have room here only for one short quotation. It is from the pen of the Duc de Lévis, and relates to the celebrated Mareschal de Richelieu, on whom Voltaire has lavished so much of his flattery. "Ce dont je suis positivement certain, c'est que cet homme spirituel (Le Mareschal de Richelieu) étoit superstitieux, et qu'il croyoit aux prédictions des astrologues et autres sottises de cet espèce. Je l'ai vu refusant à Versailles d'aller faire sa cour au fils aîné de Louis XVI. en disant sérieusement, qu'il savoit que cet enfant n'étoit point destiné au trône. Cette crédulité superstitieuse, générale pendant la ligue, étoit encore très commune sous la régence lorsque le Duc de Richelieu entra dans le monde; par la plus bizarre des inconséquences, elle s'allioit très bien avec la plus grande impiété, et la plupart des materialistes croyoient aux esprits; aujourd'hui, ce genre de folie est très rare; mais beaucoup de gens, qui se moquent des astrologues, croient à des prédictions d'une autre espèce." (*Souvenirs et Portraits*, par M. de Lévis, à Paris, 1818.)

Some extraordinary facts of the same kind are mentioned in the *Memoirs of the Marquis de Bouillé*. According to him, Frederic the Great himself was not free from this sort of superstition.

NOTE (P.) p. 63.

THE following estimate of Leibnitz, considered in comparison with his most distinguished contemporaries, approaches, on the whole, very nearly to the truth; although some doubts may be entertained about the justness of the decision in the last clause of the sentence. "Leibnitz, aussi hardi que Descartes aussi subtil que Bayle, peut-être moins profond que Newton, et moins sage que Locke, mais seul universel entre tous ces grand hommes, paroît avoir embrassé le domaine de la raison dans toute son étendue, et avoir contribué le plus à répandre cet esprit philosophique que fait aujourd'hui la gloire de notre siècle." (Bailly, *Eloge de Leibnitz*.)

I have mentioned in the text only a part of the learned labours of Leibnitz. It remains to be added, that he wrote also on various subjects connected with chemistry, medicine, botany, and natural history; on the philosophy and language of the Chinese; and on numberless other topics of subordinate importance. The philological discussions and etymological collections, which occupy so large a space among his works, would (even if he had produced nothing else) have been no inconsiderable memorials of the activity and industry of his mind.

Manifold and heterogeneous as these pursuits may at first appear, it is not difficult to trace the

thread by which his curiosity was led from one of them to another. I have already remarked a connection of the same sort between his different metaphysical and theological researches; and it may not be altogether uninteresting to extend the observation to some of the subjects enumerated in the foregoing paragraph.

The studies by which he first distinguished himself in the learned world (I pass over that of jurisprudence,¹ which was imposed on him by the profession for which he was destined) were directed to the antiquities of his own country; and more particularly to those connected with the history of the House of Brunswick. With this view he ransacked, with an unexampled industry, the libraries, monasteries, and other archives, both of Germany and of Italy; employing in this ungrateful drudgery several of the best and most precious years of his life. Mortified, however, to find how narrow the limits are, within which the range of written records is confined, he struck out for himself and his successors a new and unexpected light, to guide them through the seemingly hopeless darkness of remote ages. This light was the study of etymology, and of the affinities of different tongues in their primitive roots;—a light at first faint and glimmering, but which, since his time, has continued to increase in brightness, and is likely to do so more and more as the world grows older. It is pleasing to see his curiosity on this subject expand, from the names of the towns and rivers and mountains in his neighbourhood, till it reached to China and other regions in the East; leading him, in the last result, to some general conclusions concerning the origin of the different tribes of our species, approximating very nearly to those which have since been drawn from a much more extensive range of *data* by Sir William Jones, and other philologists of the same school.

As an additional light for illustrating the antiquities of Germany, he had recourse to natural history; examining, with a scientific eye, the shells and other marine bodies everywhere to be found in Europe, and the impressions of plants and fishes (some of them unknown in this part of the world) which are distinctly legible, even by the unlettered observer, on many of our fossils. In entering upon this research, as well as on the former, he seems to have had a view to Germany alone; on the state of which (he tells us), prior to all historical documents, it was his purpose to prefix a discourse to his History of the House of Brunswick. But his imagination soon took a bolder flight, and gave birth to his *Protogæa*;—a dissertation which (to use his own words) had for its object “to ascertain the original face of the earth, and to collect the vestiges of its earliest history from the monuments which nature herself has left of her successive operations on its surface.” It is a work, which, wild and extravagant as it may now be regarded, is spoken of by Buffon with much respect; and is considered by Cuvier as the ground-work of Buffon’s own system on the same subject.

In the connection which I have now pointed out between the Historical, the Philological, and the Geological speculations of Leibnitz, Helvetius might have fancied that he saw a new exemplification of the law of continuity; but the true light in which it ought to be viewed, is as a faithful picture of a philosophical mind emancipating itself from the trammels of local and conventional details, and gradually rising from subject to subject, till it embraces in its survey those nobler inquiries which, sooner or later, will be equally interesting to every portion of the human race.²

¹ Bailly, in his *Eloge on Leibnitz*, speaks of him in terms of the most enthusiastic praise, as a philosophical jurist, and as a man fitted to become the legislator of the human race. To me, I must own, it appears, that there is no part of his writings in which he discovers less of his characteristic originality, than where he professes to treat of the law of nature. On these occasions, how inferior does he appear to Grotius, not to speak of Montesquieu and his disciples!

² In the above note, I have said nothing of Leibnitz’s project of a philosophical language, founded on an alphabet of Human

NOTE (Q.) p. 70.

OF Locke's affectionate regard for Collins, notwithstanding the contrariety of their opinions on some questions of the highest moment, there exist many proofs in his letters, published by M. Des Maizeaux. In one of these, the following passage is remarkable. It is dated from Oates in Essex, 1703, about a year before Locke's death.

"You complain of a great many defects; and that very complaint is the highest recommendation I could desire to make me love and esteem you, and desire your friendship. And if I were now setting out in the world, I should think it my great happiness to have such a companion as you, who had a true relish for truth; would in earnest seek it with me; from whom I might receive it undisguised; and to whom I might communicate what I thought true freely. Believe it, my good friend, to love truth for truth's sake, in the principal part of human perfection in this world, and the seed-plot of all other virtues; and, if I mistake not, you have as much of it as ever I met with in any body. What, then, is there wanting to make you equal to the best; a friend for any one to be proud of?" The whole of Locke's letters to Collins are highly interesting and curious; more particularly that which he desired to be delivered to him after his own death. From the general tenor of these letters, it may be inferred, that Collins had never let Locke fully into the secret of those pernicious opinions which he was afterwards at so much pains to disseminate.

NOTE (R.) p. 72.

IN addition to the account of Spinoza given in Bayle, some interesting particulars of his history may be learnt from a small volume, entitled, *La Vie de B. de Spinoza, Tirée des écrits de ce Fameux Philosophe, et du témoignage de plusieurs personnes dignes de foi, qui l'ont connu particulièrement: par Jean Colerus, Ministre de l'Eglise Lutherienne de la Haye. 1706.*¹ The book is evidently written by a man altogether unfit to appreciate the merits or demerits of Spinoza as an author; but it is not without some value to those who delight in the study of human character, as it supplies some chasms in the narrative of Bayle, and has every appearance of the most perfect impartiality and candour.

According to this account, Spinoza was a person of the most quiet and inoffensive manners; of singular temperance and moderation in his passions; contented and happy with an income which barely supplied him with the necessaries of life; and of too independent a spirit to accept of any addition to it, either from the favour of princes, or the liberality of his friends. In conformity to

Thoughts, as he has nowhere given us any hint of the principles on which he intended to proceed in its formation, although he has frequently alluded to the practicability of such an invention in terms of extraordinary confidence. (For some remarks on these passages in his works, see *Philosophy of the Human Mind*, Vol. II. pp. 143, *et seq.*) In some of Leibnitz's expressions on this subject, there is a striking resemblance to those of Descartes in one of his letters. (See the preliminary discourse prefixed to the *Abbe Emery's Pensées de Descartes*, p. xiv. *et seq.*)

In the ingenious essay of Michaelis *On the Influence of Opinions on Language, and of Language on Opinions* (which obtained the prize from the Royal Society of Berlin in 1759), there are some very acute and judicious reflections on the impossibility of carrying into effect, with any advantage, such a project as these philosophers had in view. The author's argument on this point seems to me decisive, in the present state of human knowledge; but who can pretend to fix a limit to the possible attainments of our posterity!

¹ The life of Spinoza by Colerus, with some other curious pieces on the same subject, is reprinted in the complete edition of Spinoza's Works, published at Jena, in 1802.

the law, and to the customs of his ancestors (which he adhered to, when he thought them not unreasonable, even when under the sentence of excommunication), he resolved to learn some mechanical trade; and fortunately selected that of grinding optical glasses, in which he acquired so much dexterity, that it furnished him with what he conceived to be a sufficient maintenance. He acquired also enough of the art of designing, to produce good portraits in chalk and china-ink, of some distinguished persons.

For the last five years of his life he lodged in the house of a respectable and religious family, who were tenderly attached to him, and from whom his biographer collected various interesting anecdotes. All of them are highly creditable to his private character, and more particularly show how courteous and amiable he must have been in his intercourse with his inferiors. In a bill presented for payment after his death, he is styled by Abraham Keveling, his barber-surgeon, *Benedict Spinoza, of blessed memory*; and the same compliment is paid to him by the tradesman who furnished gloves to the mourners at his funeral.

These particulars are the more deserving of notice, as they rest on the authority of a very zealous member of the Lutheran communion, and coincide exactly with the account given of Spinoza by the learned and candid Mosheim. "This man (says he) observed, in his conduct, the rules of wisdom and probity much better than many who profess themselves Christians; nor did he ever endeavour to pervert the sentiments or to corrupt the morals of those with whom he lived; or to inspire, in his discourse, a contempt of religion or virtue." (*Eccles. History*, translated by Dr Maclaine, Vol. IV. p. 252.)

Among the various circumstances connected with Spinoza's domestic habits, Colerus mentions one very trifling singularity, which appears to me to throw a strong light on his general character, and to furnish some apology for his eccentricities as an author. The extreme feebleness of his constitution (for he was consumptive from the age of 20) having unfitted him for the enjoyment of convivial pleasures, he spent the greater part of the day in his chamber alone; but when fatigued with study, he would sometimes join the family-party below, and take a part in their conversation, however insignificant its subject might be. One of the amusements with which he was accustomed to unbend his mind, was that of entangling flies in a spider's web, or of setting spiders a-fighting with each other; on which occasions (it is added) he would observe their combats with so much interest, that it was not unusual for him to be seized with immoderate fits of laughter. Does not this slight *trait* indicate very decidedly a tendency to insanity; a supposition by no means incompatible (as will be readily admitted by all who have paid any attention to the phenomena of madness) with that logical *acumen* which is so conspicuous in some of his writings.

His irreligious principles he is supposed to have adopted, in the first instance, from his Latin preceptor Vander Ende, a physician and classical scholar of some eminence; but it is much more probable, that his chief school of atheism was the synagogue of Amsterdam; where, without any breach of charity, a large proportion of the more opulent class of the assembly may be reasonably presumed to belong to the ancient sect of *Sadducees*.* (This is, I presume, the idea of Heineccius in the following passage; "Quamvis Spinoza Cartesii principia methodo mathematica demonstrata dederit; Pantheismum tamen ille non ex Cartesio didicit, sed domi habuit, quos sequeretur." In proof of this, he refers to a book entitled *Spinozismus in Judaismo*, by Waechterus.) The blasphemous curses pronounced upon him in the sentence of excommunication were not well calculated to recall him to the faith of his ancestors: and when combined with his early and hereditary

prejudices against Christianity, may go far to account for the indiscriminate war which he afterwards waged against priests of all denominations.

The ruling passion of Spinoza seems to have been the love of fame. "It is owned (says Bayle) that he had an extreme desire to immortalize his name, and would have sacrificed his life to that glory, though he should have been torn to pieces by the mob." (Art. *Spinoza*.)

NOTE (S. p. 79.)

IN proof of the impossibility of Liberty, Collins argues thus :

"A second reason to prove man a necessary agent is, because all his actions have a beginning. For whatever has a beginning must have a cause; and every cause is a necessary cause.

"If anything can have a beginning, which has no cause, then nothing can produce something. And if nothing can produce something, then the world might have had a beginning without a cause; which is an absurdity not only charged on atheists, but is a real absurdity in itself. * * * * Liberty, therefore, or a power to act or not to act, to do this or another thing under the same causes, is an impossibility and Atheistical."¹

"And as Liberty stands, and can only be grounded on the absurd principles of Epicurean atheism; so the Epicurean atheists, who were the most popular and most numerous sect of the atheists of antiquity, were the great assertors of liberty; as, on the other side, the Stoics, who were the most popular and numerous sect among the religionaries of antiquity, were the great assertors of fate and necessity." (Collins, p. 54.)

As to the above reasoning of Collins, it cannot be expected that I should, in the compass of a Note, "boul't this matter to the bran." It is sufficient here to remark, that it derives all its plausibility from the unqualified terms in which the maxim (*μὴδὲν ἀναγκάζει*) has frequently been stated. "In the idea of every change (says Dr Price, a zealous advocate for the freedom of the will) is included that of its being an effect." (*Review*, &c. p. 30, 3d Edition.) If this maxim be literally admitted without any explanation or restriction, it seems difficult to resist the conclusions of the Necessitarians. The proper statement of Price's maxim evidently is, that "in every change we perceive in *inanimate* matter, the idea of its being an effect is necessarily involved;" and that he himself understood it under this limitation appears clearly from the application he makes of it to the point in dispute. As to intelligent and active beings, to affirm that they possess the power of self-determination, seems to me to be little more than an identical proposition. Upon an accurate analysis of the meaning of words, it will be found that the idea of an *efficient* cause implies the idea of *Mind*; and, consequently, that it is absurd to ascribe the volitions of *mind* to the efficiency of causes foreign to itself. To do so must unavoidably involve us in the inconsistencies of Spinozism; by forcing us to conclude that everything is passive, and nothing active in the universe; and, consequently, that the idea of a *First Cause* involves an impossibility.—But upon these hints I must not enlarge at present; and shall, therefore, confine myself to what falls more immediately within the scope of this Discourse, Collins's Historical Statement with respect to the tenets of the Epicureans and the Stoics.

¹ To the same purpose Edwards attempts to show, that "the scheme of free-will (by affording an exception to that dictate of common sense which refers every event to a cause) would destroy the proof *a posteriori* for the being of God."

In confirmation of his assertion concerning the former, he refers to the following well known lines of Lucretius :

Denique si semper motus connectitur omnia.

&c. &c.

(*Lucret*, Lib. 2. v. 251.)

On the obscurity of this passage, and the inconsistencies involved in it, much might be said ; but it is of more importance, on the present occasion, to remark its complete repugnance to the whole strain and spirit of the Epicurean Philosophy. This repugnance did not escape the notice of Cicero, who justly considers Epicurus as having contributed more to establish, by this puerile subterfuge, the authority of Fatalism, than if he had left the argument altogether untouched. “*Nec vero quisquam magis confirmare mihi videtur non modo fatum, verum etiam necessitatem et vim omnium rerum, sustulisseque motus animi voluntarios, quam hic qui aliter obsistere fato fatetur se non potuisse nisi ad has commenticias declinationes confugisset.*” (*Liber de Fato*, cap. 20.)

On the noted expression of Lucretius (*fatis avolsa voluntas*) some acute remarks are made in a note on the French translation by M. de la Grange. They are not improbably from the pen of the Baron d'Holbach, who is said to have contributed many notes to this translation. Whoever the author was, he was evidently strongly struck with the inconsistency of this particular tenet with the general principles of the Epicurean System.

“On est surpris qu' Epicure fonde la liberté humaine sur la déclinaison des atomes. On demande si cette déclinaison est nécessaire, ou si elle est simplement accidentelle. Nécessaire, comment la liberté peut elle en être le resultat ? Accidentelle, par quoi est elle déterminée ? Mais on devrait bien plutôt être surpris, qu'il lui soit venu en idée de rendre l'homme libre dans un système qui suppose un enchainement nécessaire de causes et d'effets. C'étoit une recherche curieuse, que la raison qui a pu faire d'Epicure l'Apôtre de la Liberté.” For the theory which follows on this point, I must refer to the work in question. (See *Traduction Nouvelle de Lucrece, avec des Notes*, par M. de la Grange, Vol. I. pp. 218, 219, 220, à Paris, 1768.)

But whatever may have been the doctrines of some of the ancient Atheists about man's free-agency, it will not be denied, that in the *History of Modern Philosophy*, the schemes of Atheism and of Necessity have been hitherto always connected together. Not that I would by any means be understood to say, that every Necessitarian must *ipso facto* be an Atheist, or even, that any presumption is afforded by a man's attachment to the former sect, of his having the slightest bias in favour of the latter ; but only that every modern Atheist I have heard of has been a Necessitarian. I cannot help adding, that the most consistent Necessitarians who have yet appeared, have been those who followed out their principles till they ended in *Spinozism*, a doctrine which differs from atheism more in words than in reality.

In what Collins says of the Stoics in the above quotation, he plainly proceeds on the supposition that all Fatalists are of course Necessitarians ;¹ and I agree with him in thinking, that this would be the case, if they reasoned logically. It is certain, however, that a great proportion of those who have belonged to the first sect have disclaimed all connection with the second. The Stoics themselves furnish one very remarkable instance. I do not know any author by whom the liberty of the will is stated in stronger and more explicit terms, than it is by Epictetus in the very first sentence of the *Enchiridion*. Indeed the Stoics seem, with their usual passion for exaggeration, to have carried their ideas about the freedom of the will to an unphilosophical extreme.

¹ Collins states this more strongly in what he says of the Pharisees. “The Pharisees, who were a religious sect, ascribed all things to fate or to God's appointment, and it was the first article of their creed, that Fate and God do all, and, consequently, they could not assert a *true* liberty when they asserted a liberty together with this fatality and necessity of all things.” (Collins, p. 54.)

If the belief of man's free-agency has thus maintained its ground among professed Fatalists, it need not appear surprising, that it should have withstood the strong arguments against it, which the doctrine of the eternal decrees of God, and even that of the Divine prescience, appear at first sight to furnish. A remarkable instance of this occurs in St Augustine (distinguished in ecclesiastical history by the title of *the Doctor of Grace*), who has asserted the liberty of the will in terms as explicit as those in which he has announced the theological dogmas with which it is most difficult to reconcile it. Nay, he has gone so far as to acknowledge the essential importance of this belief, as a motive to virtuous conduct. "Quocirca nullo modo cogimur, aut retentâ præscientiâ Dei, tollere voluntatis arbitrium, aut retento voluntatis arbitrio, Deum, quod nefas est, negare præscium futurorum, sed utrumque amplectimur, utrumque fideliter et veraciter confitemur: illud, ut bene credamus; hoc ut bene vivamus."

Descartes has expressed himself on this point nearly to the same purpose with St Augustine. In one passage he asserts, in the most unqualified terms, that God is the cause of all the actions which depend on the Free-will of Man; and yet, that the Will is really free, he considers as a fact perfectly established by the evidence of consciousness. "Sed quemadmodum existentie divinæ cognitione non debet liberi nostri arbitrii certitudinem tollere, quia illud in nobismet ipsis experimur et sentimus; ita neque liberi nostri arbitrii cognitio existentiam Dei apud nos dubiam facere debet. Independentia enim illa quam experimur, atque in nobis persentiscimus, et quæ actionibus nostris laude vel vituperio dignis efficiendis sufficit, non pugnat cum dependentia alterius generis, secundum quam omnia Deo subjiciuntur." (*Cartesii Epistolæ*, Epist. VIII. IX. Pars i.) These letters form part of his correspondence with the Princess Elizabeth, daughter of Frederick, King of Bohemia, and Elector Palatine.

We are told by Dr Priestley, in the very interesting *Memoirs of his own Life*, that he was educated in the strict principles of Calvinism; and yet it would appear, that while he remained a Calvinist, he entertained no doubt of his being a free-agent. "The doctrine of necessity (he also tells us) he first learned from Collins;¹ and was established in the belief of it by Hartley's *Observations on Man*." (*Ibid.* p. 19.) He farther mentions in another work, that "he was not a ready convert to the doctrine of necessity, and that, like Dr Hartley himself, he gave up his liberty with great reluctance." (*Preface to the Doctrine of Philosophical Necessity Illustrated*, 2d Edit. Birmingham, 1782, p. xxvii.)

These instances afford a proof, I do not say of the compatibility of man's free-agency with those schemes with which it seems most at variance, but of this compatibility in the opinion of some of the profoundest thinkers who have turned their attention to the argument. No conclusion, therefore, can be drawn against a man's belief in his own free-agency, from his embracing other metaphysical or theological tenets, with which it may appear to ourselves impossible to reconcile it.

As for the notion of liberty, for which Collins professes himself an advocate, it is precisely that of his predecessor Hobbes, who defines a free-agent to be, "he that can do if he will, and forbear if he will." (*Hobbes's Works*, p. 484, fol. ed.) The same definition has been adopted by Leibnitz, by Gravesande, by Edwards, by Bonnet, and by all our later necessitarians. It cannot be better ex-

¹ We are elsewhere informed by Priestley, that "it was in consequence of reading and studying the *Inquiry* of Collins, he was first convinced of the truth of the doctrine of Necessity, and was enabled to see the fallacy of most of the arguments in favour of Philosophical Liberty: though (he adds) I was much more confirmed in this principle by my acquaintance with *Hartley's Theory of the Human Mind*; a work to which I owe much more than I am able to express."—(*Preface*, &c. &c. p. xxvii.)

pressed than in the words of Gravesande: "*Facultas faciendi quod libuerit, quæcunque fuerit voluntatis determinatio.*" (*Introd. ad Philosoph.* § 115.)

Dr Priestley ascribes this peculiar notion of free-will to Hobbes as its author;¹ but it is, in fact, of much older date even among modern metaphysicians; coinciding exactly with the doctrine of those scholastic divines who contended for the *Liberty of Spontaneity*; in opposition to the *Liberty of Indifference*. It is, however, to Hobbes that the partizans of this opinion are indebted for the happiest and most popular illustration of it that has yet been given. "I conceive (says he) liberty to be rightly defined, The absence of all the impediments to action that are not contained in the nature and intrinsic quality of the agent. As, for example, the water is said to descend *freely*, or to have liberty to descend by the channel of the river, because there is no impediment that way: but not across, because the banks are impediments. And though water cannot ascend, yet men never say, it wants the *liberty* to ascend, but the *faculty* or power, because the impediment is in the nature of the water, and intrinsic. So also we say, he that is tied wants the *liberty* to go, because the impediment is not in him, but in his hands; whereas we say not so of him who is sick or lame, because the impediment is in himself." (*Treatise of Liberty and Necessity.*)

According to Bonnet, "moral liberty is the power of the mind to obey without constraint the impulse of the motives which act upon it." This definition, which is obviously the same in substance with that of Hobbes, is thus very justly, as well as acutely, animadverted on by Cuvier. "N'admettant aucune action sans motif, comme dit-il, il n'y a aucun effet sans cause, Bonnet définit la *liberté morale* le pouvoir de l'âme de suivre sans contrainte les motifs dont elle éprouve l'impulsion; et résout ainsi les objections que l'on tire de la prévision de Dieu; mais peut-être aussi détournent-til l'idée qu'on se fait d'ordinaire de la liberté. Malgré ces opinions que touchent au Matérialisme et au Fatalisme, Bonnet fut très religieux." (*Biographie Universelle*, à Paris, 1812. Art. Bonnet.)

From this passage, it appears, that the very ingenious writer was as completely aware as Clarke or Reid, of the unsoundness of the definition of *moral liberty* given by Hobbes and his followers; and that the ultimate tendency of the doctrine which limits the free-agency of man to (what has been called) the *liberty of spontaneity*, was the same, though in a more disguised form, with that of fatalism.

For a complete exposure of the futility of this definition of *liberty*, as the word is employed in the controversy about man's free-agency, I have only to refer to Clarke's remarks on Collins, and to Dr Reid's *Essays on the Active Powers of Man*. In this last work, the various meanings of this very ambiguous word are explained with great accuracy and clearness.

The only two opinions which, in the actual state of metaphysical science, ought to be stated in contrast, are that of Liberty (or free-will) on the one side, and that of Necessity on the other. As to the *Liberty of Spontaneity* (which expresses a fact altogether foreign to the point in question), I can conceive no motive for inventing such a phrase, but a desire in some writers to veil the scheme of necessity from their readers, under a language less revolting to the sentiments of mankind: and, in others, an anxiety to banish it as far as possible from their own thoughts, by substituting, instead of the terms in which it is commonly expressed, a circumlocution which seems, on a superficial view, to concede something to the advocates for liberty.

¹ "The doctrine of philosophical necessity," says Priestley, "is in reality a modern thing, not older, I believe, than Mr Hobbes. Of the Calvinists, I believe Mr Jonathan Edwards to be the first." (*Illustrations of Philosophical Necessity*, p. 195.)

Supposing this statement to be correct, does not the very modern date of Hobbes's alleged *discovery* furnish a very strong presumption against it?

If this phrase (the *Liberty of Spontaneity*) should fall into disuse, the other phrase (the *Liberty of Indifference*),¹ which is commonly stated in opposition to it, would become completely useless; nor would there be occasion for qualifying with any epithet, the older, simpler, and much more intelligible word *Free-will*.

The distinction between *physical* and *moral* necessity I conceive to be not less frivolous than those to which the foregoing animadversions relate. On this point I agree with Diderot, that the word *necessity* (as it ought to be understood in this dispute) admits but of one interpretation.

NOTE (T.) p. 79.

To the arguments of Collins, against man's free-agency, some of his successors have added, the inconsistency of this doctrine with the known *effects of education* (under which phrase they comprehend the moral effects of all the external circumstances in which men are involuntarily placed) in forming the characters of individuals.

The plausibility of this argument (on which much stress has been laid by Priestley and others) arises entirely from the mixture of truth which it involves; or, to express myself more correctly, from the evidence and importance of the *fact* on which it proceeds, when that fact is stated with due limitations.

That the influence of *education*, in this comprehensive sense of the word, was greatly underrated by our ancestors, is now universally acknowledged; and it is to Locke's writings, more than to any other single cause, that the change in public opinion on this head is to be ascribed. On various occasions, he has expressed himself very strongly with respect to the *extent* of this influence; and has more than once intimated his belief, that the great majority of men continue through life what early education had made them. In making use, however, of this strong language, his object (as is evident from the opinions which he has avowed in other parts of his works) was only to arrest the attention of his readers to the practical lessons he was anxious to inculcate; and not to state a *metaphysical fact* which was to be literally and rigorously interpreted in the controversy about liberty and necessity. The only sound and useful *moral* to be drawn from the *spirit* of his observations is, the duty of gratitude to Heaven for all the blessings, in respect of education and of external situation, which have fallen to our own lot; the impossibility of ascertaining the involuntary misfortunes by which the seeming demerits of others may have been in part occasioned, and in the same proportion diminished; and the consequent obligation upon ourselves, to think as charitably as possible of their conduct, under the most unfavourable appearances. The truth of all this I conceive to be implied in these words of Scripture, "To whom much is given, of him much will be required;" and, if possible, still more explicitly and impressively, in the Parable of the Talents.

Is not the use which has been made by Necessitarians of Locke's *Treatise on Education*, and other books of a similar tendency, only one instance more of that disposition, so common among metaphysical Sciologists, to appropriate to themselves the conclusions of their wiser and more sober predecessors, under the startling and imposing disguise of universal maxims, admitting neither of exception nor restriction? It is thus that Locke's judicious and refined remarks on the *Association of Ideas* have been exaggerated to such an extreme in the coarse caricatures of Hartley and of Priest-

¹ Both phrases are favourite expressions with Lord Kames in his discussions on this subject. See in particular the Appendix to his *Essay on Liberty and Necessity*, in the last Edition of his *Essays on Morality and Natural Religion*.

ley, as to bring, among cautious inquirers, some degree of discredit on one of the most important doctrines of modern philosophy. Or, to take another case still more in point; it is thus that Locke's reflections on the effects of education in modifying the intellectual faculties, and (where skilfully conducted) in supplying their original defects, have been distorted into the puerile paradox of Helvetius, that the mental capacities of the whole human race are the same at the moment of birth. It is sufficient for me here to throw out these hints, which will be found to apply equally to a large proportion of other theories started by modern metaphysicians.

Before I finish this note, I cannot refrain from remarking, with respect to the argument for Necessity drawn from the Divine prescience, that, if it be conclusive, it only affords an additional confirmation of what Clarke has said concerning the identity of the creed of the Necessitarians with that of the Spinozists. For, if God certainly foresees all the future volitions of his creatures, he must, for the same reason, foresee all *his own* future volitions; and if this knowledge infers a necessity of volition in the one case, how is it possible to avoid the same inference in the other?

NOTE (U.) p. 80.

A SIMILAR application of St Paul's comparison of the potter is to be found both in Hobbes and in Collins. Also, in a note annexed by Cowley to his ode entitled *Destiny*; an ode written (as we are informed by the author) "upon an extravagant supposition of two angels playing a game at chess; which, if they did, the spectators would have reason as much to believe that the pieces moved themselves, as we have for thinking the same of mankind, when we see them exercise so many and so different actions. It was of old said by Plautus, *Dii nos quasi pilas homines habent*. "We are but tennis-balls for the gods to play withal," which they strike away at last, and still call for new ones; and St Paul says, "*We are but the clay in the hand of the potter.*"

For the comparison of *the potter*, alluded to by these different writers, see the epistle to the Romans, Chap. ix. verses 18, 19, 20, 21. Upon these verses the only comment which I have to offer is a remark of the Apostle Peter; that "In the epistles of our beloved brother Paul are some things hard to be understood, which they that are unlearned and unstable wrest unto their own destruction."

The same similitude of *the potter* makes a conspicuous figure in the writings of Hobbes, who has availed himself of this, as of many other insulated passages of Holy Writ, in support of principles which are now universally allowed to strike at the very root of religion and morality. The veneration of Cowley for Hobbes is well known, and is recorded by himself in the ode which immediately precedes that on *Destiny*. It cannot, however, be candidly supposed, that Cowley understood the whole drift of Hobbes' doctrines. The contrary, indeed, in the present instance, is obvious from the ode before us; for while Cowley supposed the angels to move, like chess-men, the inhabitants of this globe, Hobbes (along with Spinoza) plainly conceived that the angels themselves, and even that Being to which he impiously gave the name of *God*, were all of them moved, like knights and pawns, by the invisible hand of fate or necessity.

Were it not for the serious and pensive cast of Cowley's mind, and his solemn appeal to the authority of the apostle, in support of the doctrine of *destiny*, one would be tempted to consider the first stanzas of this ode in the light of a *jeu d'esprit*, introductory to the very characteristic and interesting picture of himself, with which the poem concludes.

NOTE (X.) p. 82.

“ Tout ce qui est doit être, par cela même que cela est. Voilà la seule bonne philosophie. Aussi longtemps que nous ne connaissons pas cet univers, comme on dit dans l'école, *a priori*, tout est nécessité. La liberté est un mot vide de sens, comme vous allez voir dans la lettre de M. Diderot.” (Lettre de Grimm au Duc de Saxe-Gotha.)

“ C'est ici mon cher, que je vais quitter le ton de prédicateur pour prendre, si je peux, celui de philosophe. Regardez-y de près, et vous verrez que le mot liberté est un mot vide de sens; qu'il n'y a point, et qu'il ne peut y avoir d'êtres libres; que nous ne sommes que ce qui convient à l'ordre général, à l'organisation, à l'éducation, et à la chaîne des événemens. Voilà ce qui dispose de nous invinciblement. On ne conçoit non plus qu'un être agisse sans motif, qu'un des bras d'une balance agisse sans l'action d'un poids, et le motif nous est toujours extérieur, étranger, attachés ou par une nature ou par une cause quelconque, qui n'est pas nous. Ce qui nous trompe, c'est la prodigieuse variété de nos actions, jointe à l'habitude que nous avons prise tout en naissant, de confondre le volontaire avec le libre. Nous avons tant loué, tant repris, nous l'avons été tant de fois, que c'est un préjugé, bien vieux que celui de croire que nous et les autres voulons, agissons librement. Mais s'il n'y a point de liberté, il n'y a point d'action qui mérite la louange ou le blâme; il n'y a ni vice, ni vertu, rien dont il faille récompenser ou châtier. Qu'est ce qui distingue donc les hommes? La bienfaisance ou la malfaisance. Le malfaisant est un homme qu'il faut détruire, en non punir; la bienfaisance est une bonne fortune, et non une vertu. Mais quoique l'homme bien ou malfaisant ne soit pas libre, l'homme n'en est pas moins un être qu'on modifie; c'est par cette raison qu'il faut détruire le malfaisant sur une place publique. De là les bons effets de l'exemple, des discours, de l'éducation, du plaisir, de la douleur, des grandeurs, de la misère, &c.; de là une sorte de philosophie pleine de commisération, qui attache fortement aux bons, qui n'irrite non plus contre le méchant, que contre un ouragan qui nous remplit les yeux de poussière. Il n'y a qu'une sorte de causes à proprement parler; ce sont les causes physiques. Il n'y a qu'une sorte de nécessité, c'est la même pour tous les êtres. Voilà ce qui me réconcilie avec le genre humain; c'est pour cette raison que je vous exhortais à la philanthropie. Adoptez ces principes si vous les trouvez bons, ou montrez-moi qu'ils sont mauvais. Si vous les adoptez, ils vous réconcilieront aussi avec les autres et avec vous-même; vous ne vous saurez ni bon ni mauvais gré d'être ce qui vous êtes. Ne rien reprocher aux autres, ne se repentir de rien; voilà les premiers pas vers la sagesse. Ce qui est hors de là est préjugé, fausse philosophie.” (*Correspondance Littéraire, Philosophique, et Critique, adressée au Duc de Saxe-Gotha*, par le Baron de Grimm et par Diderot. Première Partie, Tom. I. pp. 300, 304, 305, 306, Londres, 1814.)

NOTE (Y.) p. 91.

SEE in Bayle the three articles *Luther*, *Knox*, and *Buchanan*. The following passage concerning *Knox* may serve as a specimen of the others. It is quoted by Bayle from the *Cosmographie Universelle* of Thevet, a writer who has long sunk into the contempt he merited, but whose zeal for legitimacy and the Catholic faith raised him to the dignity of almoner to Catherine de Medicis, and of historiographer to the King of France. I borrow the translation from the English *Historical Dictionary*.

“ During that time the Scots never left England in peace; it was when Henry VIII. played his

pranks with the chalices, relics, and other ornaments of the English churches; which tragedies and plays have been acted in our time in the kingdom of Scotland, by the exhortations of Noptz,¹ the first Scots minister of the bloody Gospel. This firebrand of sedition could not be content with barely following the steps of Luther, or of his master, Calvin, who had not long before delivered him from the galleys of the Prior of Capua, where he had been three years for his crimes, unlawful amours, and abominable fornications; for he used to lead a dissolute life, in shameful and odious places, and had been also found guilty of the parricide and murder committed on the body of the Archbishop of St Andrew's, by the contrivances of the Earl of Rophol, of James Lesclé, John Lesclé, their uncle, and William du Coy. This simonist, who had been a priest of our church, being fattened by the benefices he had enjoyed, sold them for ready money; and finding that he could not make his cause good, he gave himself up to the most terrible blasphemies. He persuaded also several devout wives and religious virgins to abandon themselves to wicked adulterers. Nor was this all. During two whole years, he never ceased to rouse the people, encouraging them to take up arms against the Queen, and to drive her out of the kingdom, which he said was elective, as it had been formerly in the time of heathenism. The Lutherans have churches and oratories. Their ministers sing psalms, and say mass; and though it be different from ours, yet they add to it the Creed, and other prayers, as we do. And when their ministers officiate, they wear the cope, the chasuble, and the surplice, as ours do, being concerned for their salvation, and careful of what relates to the public worship. Whereas the Scots have lived these twelve years past without laws, without religion, without ceremonies, constantly refusing to own a King or a Queen, as so many brutes, suffering themselves to be imposed upon by the stories told them by this arch-hypocrite Noptz, a traitor to God and to his country, rather than to follow the pure Gospel, the councils, and the doctrine of so many holy doctors, both Greek and Latin, of the Catholic church."

If any of my readers be yet unacquainted with the real character and history of this distinguished person, it may amuse them to compare the above passage with the very able, authentic, and animated account of his life, lately published by the reverend and learned Dr M'Crie.

NOTE (Z.) p. 100.

DR BLAIR (whose estimate of the distinguishing beauties and imperfections of Addison's style reflects honour on the justness and discernment of his taste) has allowed himself to be carried along much too easily, by the vulgar sneers at Addison's want of philosophical depth. In one of his lectures on rhetoric he has even gone so far as to accuse Addison of misapprehending, or, at least, of *mis-stating* Locke's doctrine concerning *secondary qualities*. But a comparison of Dr Blair's own statement with that which he censures, will not turn out to the advantage of the learned critic; and I willingly lay hold of this example, as the point at issue turns on one of the most refined questions of metaphysics. The words of Addison are these:—

" Things would make but a poor appearance to the eye, if we saw them only in their proper figures and motions. And what reason can we assign for their exciting in us many of those ideas which are different from any thing that exists in the objects themselves (for such are *light* and *colours*), were it not to add supernumerary ornaments to the universe, and make it more agreeable to the imagination?"

¹ Thus Thevet (says Bayle) writes the name of Knox.

After quoting this sentence, Dr Blair proceeds thus:—

“ Our author is now entering on a theory, which he is about to illustrate, if not with much philosophical accuracy, yet with great beauty of fancy and glow of expression. A strong instance of his want of accuracy appears in the manner in which he opens the subject. For what meaning is there in things *exciting in us many of those ideas which are different from any thing that exists in the objects* ? No one, sure, ever imagined that our ideas exist in the objects. Ideas, it is agreed on all hands, can exist no where but in the mind. What Mr Locke’s philosophy teaches, and what our author should have said, is, *exciting in us many ideas of qualities which are different from any thing that exists in the objects.*”

Let us now attend to Locke’s theory as stated by himself:—

“ From whence I think it is easy to draw this observation, That the *ideas* of primary qualities of bodies are *resemblances* of them, and *their patterns* do really exist in the bodies themselves, but the *ideas* produced in us by these secondary qualities have *no resemblance* of them at all. There is nothing like our ideas existing in the bodies themselves. They are in the bodies we denominate from them, only a power to produce these sensations in us. And what is sweet, blue, or warm in *idea*, is but the certain bulk, figure, and motion of the insensible parts in the bodies themselves, which we call so.”

The inaccuracy of Locke in conceiving that our *ideas* of primary qualities are *resemblances* of these qualities, and that the *patterns* of such ideas exist in the bodies themselves, has been fully exposed by Dr Reid. But the *repetition* of Locke’s inaccuracy (supposing Addison to have been really guilty of it) should not be charged upon him as a *deviation* from his master’s doctrine. To all, however, who understand the subject, it must appear evident, that Addison has, in this instance, *improved* greatly on Locke, by keeping out of view what is most exceptionable in his language, while he has retained all that is solid in his doctrine. For my own part, I do not see how Addison’s expressions could be altered to the better, except, perhaps, by substituting the words *unlike to*, instead of *different form*. But in this last phrase, Addison has been implicitly followed by Dr Blair, and certainly would not have been disavowed as an interpreter by Locke himself. Let me add, that Dr Blair’s proposed emendation (“*exciting in us many ideas of qualities, which are different from any thing that exists in the objects*”), if not wholly unintelligible, deviates much farther from Locke’s meaning than the correspondent clause in its original state. The additional words *of qualities* throw an obscurity over the whole proposition, which was before sufficiently precise and perspicuous.¹

My principal reason for offering these remarks in vindication of Addison’s account of secondary qualities was, to prepare the way for the sequel of the passage animadverted on by Dr Blair.

¹ Another passage, afterwards quoted by Dr Blair, might have satisfied him of the clearness and accuracy of Addison’s ideas on the subject.

“ I have here supposed that my reader is acquainted with that great modern discovery, which is, at present, universally acknowledged by all the inquirers into natural philosophy; namely, that light and colours, *as apprehended by the imagination*, are only ideas in the mind, and, not qualities that have any existence in matter. As this is a truth which has been proved incontestably by many modern philosophers, if the English reader would see the notion explained at large, he may find it in the eighth book of Mr Locke’s *Essay on Human Understanding*.”

I have already taken notice (*Elements of the Philosophy of the Human Mind*, Vol. I. Note P.) of the extraordinary precision of the above statement, arising from the clause printed in Italics. By a strange slip of memory I ascribed the merit of this very judicious qualification, not to Addison, but to Dr Akenside, who transcribed it from the Spectator.

The last quotation affords me also an opportunity of remarking the correctness of Addison’s information about the history of this doctrine, which most English writers have conceived to be an original speculation of Locke’s. From some of Addison’s expressions, it is more than probable, that he had derived his first knowledge of it from Malebranche.

"We are everywhere entertained with pleasing shows and apparitions. We discover imaginary glories in the heavens and in the earth, and see some of this visionary beauty poured out upon the whole creation. But what a rough unsightly sketch of nature should we be entertained with, did all her colouring disappear, and the several distinctions of light and shade vanish?¹ In short, our souls are delightfully lost and bewildered in a pleasing delusion, and we walk about like the enchanted hero of a romance, who sees beautiful castles, woods, and meadows, and, at the same time, hears the warbling of birds and the purling of streams: but, upon the finishing of some secret spell, the fantastic scene breaks up, and the disconsolate knight finds himself on a barren heath, or in a solitary desert."

In this passage one is at a loss whether most to admire the author's depth and refinement of thought, or the singular felicity of fancy displayed in its illustration. The image of the *enchanted hero* is so unexpected, and, at the same time, so exquisitely appropriate, that it seems itself to have been conjured up by an enchanter's wand. Though introduced with the unpretending simplicity of a poetical simile, it has the effect of shedding the light of day on one of the darkest corners of metaphysics. Nor is the language in which it is conveyed unworthy of the attention of the critic; abounding throughout with those natural and happy graces, which appear artless and easy to all but to those who have attempted to copy them.

The praise which I have bestowed on Addison as a commentator on this part of Locke's *Essay* will not appear extravagant to those who may take the trouble to compare the conciseness and elegance of the foregoing extracts with the prolixity and homeliness of the author's text. (See *Locke's Essay*, Book II. chap. viii. §§ 17, 18.) It is sufficient to mention here, that his chief illustration is taken from "the effects of manna on the stomach and guts."

NOTE (AA.) p. 111.

For the following note I am indebted to my learned friend Sir William Hamilton, Professor of Universal History in the University of Edinburgh.

"The *Clavis Universalis* of Arthur Collier, though little known in England, has been translated into German. It is published in a work entitled "*Samlung*, &c. &c. literally, "A Collection of the most distinguished authors who deny the existence of their own bodies, and of the whole material world,—containing the dialogues of Berkeley, between Hylas and Philonous, and Collier's *Universal Essay* translated, with Illustrative Observations, and an Appendix, wherein the existence of Body is demonstrated, by John Christopher Eschenbach, Professor of Philosophy in Rostock." (Rostock, 1756, 8vo.) The remarks are numerous, and show much reading. The Appendix contains, 1. An exposition of the opinion of the Idealists, with its grounds and arguments. 2. A proof of the external existence of body. The argument on which he chiefly dwells to show the existence of matter is the same with that of Dr Reid, in so far as he says "a direct proof must not here be expected; in regard to the fundamental principles of human nature, this is seldom possible, or rather is absolutely impossible." He argues at length, that the Idealist has no better proof of the existence of his soul than of the existence of his body; "when an Idealist says, *I am a thinking being; of this I am certain from internal conviction*;—I would ask from whence he derives this certainty, and why he ex-

¹ On the supposition made in this sentence, the face of Nature, instead of presenting a "rough unsightly sketch," would, it is evident, become wholly invisible. But I need scarcely say, this does not render Mr Addison's allusion less pertinent.

cludes from this conviction the possibility of deception? He has no other answer than this, *I feel it. It is impossible that I can have any representation of self without the consciousness of being a thinking being.* In the same manner, Eschenbach argues that the *feeling* applies to the existence of body, and that the ground of belief is equally strong and conclusive, in respect to the reality of the objective, as of the subjective, in perception."

NOTE (BB.) p. 132.

"*And yet Diderot, in some of his lucid intervals, seems to have thought and felt very differently.*"

THE following passage (extracted from his *Pensées Philosophiques*) is pronounced by La Harpe to be not only one of the most eloquent which Diderot has written, but to be one of the best comments which is any where to be found on the Cartesian argument for the existence of God. It has certainly great merit in point of reasoning, but I cannot see with what propriety it can be considered as a comment upon the argument of Descartes; nor am I sure if, in point of eloquence, it be as well suited to the English as to the French taste.

"Convenez qu'il y auroit de la folie à refuser à vos semblables la faculté de penser. Sans doute, mais que s'ensuit-il de là? Il s'ensuit, que si l'univers, que dis-je l'univers, si l'aile d'un papillon m'offre des traces mille fois plus distinctes d'une intelligence que vous n'avez d'indices que votre semblable à la faculté de penser, il est mille fois plus fou de nier qu'il existe un Dieu, que de nier que votre semblable pense. Or, que cela soit ainsi, c'est à vos lumières, c'est à votre conscience que j'en appelle. Avez-vous jamais remarqué dans les raisonnemens, les actions, et la conduite de quelque homme que ce soit, plus d'intelligence, d'ordre, de sagacité, de conséquence, que dans le mécanisme d'un insècte? La divinité n'est elle pas aussi clairement empreinte dans l'œil d'un ciron, que la faculté de penser dans les écrits du grand Newton? (Quoi! le monde formé prouverait moins d'intelligence, que le monde expliqué? Quelle assertion! l'intelligence d'un premier être ne m'est pas mieux démontrée par ses ouvrages, que la faculté de penser dans un philosophe par ses écrits? Songez donc que je ne vous objecte que l'aile d'un papillon, quand je pourrais vous écraser du poids de l'univers."

This, however, was certainly not the creed which Diderot professed in his more advanced years. The article, on the contrary, which immediately follows the foregoing quotation, there is every reason to think, expresses his real sentiments on the subject. I transcribe it at length, as it states clearly and explicitly the same argument which is indirectly hinted at in a late publication by a more illustrious author.

"J'ouvre les cahiers d'un philosophe célèbre, et je lis. Athées, je vous accorde que le mouvement est essentiel à la matière; qu'en concluez-vous? que le monde resulte du jet fortuit d'atomes? J'aimerois autant que vous me dissiez que l'Iliade d'Homère ou la Henriade de Voltaire est un resultat de jets fortuits de caractères?" Je me garderai bien de faire ce raisonnement à un athée. Cette comparaison lui donneroit beau jeu. Selon les lois de l'analyse des sorts, me diroit-il, je ne dois être surpris qu'une chose arrive, lorsqu'elle est possible, et que la difficulté de l'événement est compensée par la quantité des jets. Il y a tels nombre de coups dans lesquels je gagerois avec avantage d'amener cent mille six à la fois avec cent mille dez. Quelle que fût la somme finie de caractères avec laquelle on me proposeroit d'engendrer fortuitement l'Iliade, il y a telle somme finie de jets qui me rendroit la proposition avantageuse; mon avantage seroit même infinie, si la quantité de jets accordée étoit infini," &c. &c. (*Pensées Philosophiques*, par Diderot, XXI.)

My chief reason for considering this as the genuine exposition of Diderot's own creed is, that he omits no opportunity of suggesting the same train of thinking in his other works. It may be distinctly traced in the following passage of his *Traité du Beau*, the substance of which he has also introduced in the article *BEAU* of the *Encyclopédie*.

“ Le beau n'est pas toujours l'ouvrage d'une cause intelligente ; le mouvement établit souvent, soit dans un être considéré solitairement, soit entre plusieurs êtres comparés entr'eux, une multitude prodigieuse de rapports surprenans. Les cabinets d'histoire naturelle en offrent un grand nombre d'exemples. Les rapports sont alors des resultats de combinaisons fortuites, du moins par rapport à nous. La nature imite en se jouant, dans cent occasions, les productions d'art ; et l'on pourroit demander, je ne dis pas si ce philosophe qui fut jeté par une tempête sur les bords d'une Ile inconnue, avoit raison de se crier, à la vue de quelques figures de geometrie ; ‘ *Courage mes amis, voici des pas d'hommes ;* ’ mais combien il faudroit remarquer de rapports dans un être, pour avoir une certitude complète qu'il est l'ouvrage d'un artiste¹ (en quelle occasion, un seul défaut de symmetrie prouveroit plus que toute somme donnée de rapports) ; comment sont entr'eux le temps de l'action de la cause fortuite, et les rapports observés dans les effets produits ; et si (à l'exception des œuvres du Tout-Puissant)² il y a des cas ou le nombre des rapports ne puisse jamais être compensé par celui des jets.”

With respect to the passages here extracted from Diderot, it is worthy of observation, that if the atheistical argument from chances be conclusive in its application to that order of things which we behold, it is not less conclusive when applied to every other possible combination of atoms which imagination can conceive, and affords a mathematical proof, that the fables of Grecian mythology, the tales of the genii, and the dreams of the Rosicrusians, *may, or rather must,* all of them, be somewhere or other realised in the infinite extent of the universe ; a proposition which, if true, would destroy every argument for or against any given system of opinions founded on the reasonableness or the unreasonableness of the tenets involved in it ; and would, of consequence, lead to the subversion of the whole frame of the human understanding.³

¹ Is not this precisely the sophistical mode of questioning known among Logicians by the name of *Sorites* or *Acervus* ? ‘ *Vitiosum sane (says Cicero) et captiosum genus.*’ (*Acad. Quest. Lib. IV. xvi.*)

² To those who enter fully into the spirit of the foregoing reasoning, it is unnecessary to observe, that this parenthetical clause is nothing better than an ironical *salvo*. If the argument proves any thing it leads to this general conclusion, that the apparent order of the universe affords no evidence whatever of the existence of a designing cause.

³ The atheistical argument here quoted from Diderot is, at least, as old as the time of Epicurus.

Nam certè neque consilio primordia rerum
Ordine se quæque, atque sagaci mente locarunt ;
Nec quos quæque darent motus pepigere profectò ;
Sed quia multimodis, multis, mutata, per omne
Ex infinito vexantur percita plagis,
Omne genus motûs, et cœtus experiundo,
Tandem deveniunt in taleis disposituras,
Qualibus hæc rebus consistit summa creata.

(Lucret. Lib. I. l. 1020.)

And still more explicitly in the following lines :

Nam cùm respicias immensi temporis omne
Præteritum spatium ; tam motus materiali
Multimodi quàm sint ; facillè hoc adcredere possis,
Semina sæpe in eodem, ut nunc sunt, ordine posta.

(Ibid. Lib. III. l. 967.)

Mr Hume, in his *Natural History of Religion*, (Sect. XI.), has drawn an inference from the internal evidence of the Heathen Mythology, in favour of the supposition, that it may not be altogether so fabulous as is commonly supposed. "The whole mythological system is so natural, that in the vast variety of planets and worlds contained in this universe, it seems more than probable that somewhere or other it is really carried into execution." The argument of Diderot goes much farther, and leads to an extension of Mr Hume's conclusion to all conceivable systems, whether natural or not.

But further, since the human mind, and all the numberless displays of wisdom and of power which it has exhibited, are ultimately to be referred to a fortuitous concourse of atoms, why might not the Supreme Being, such as we are commonly taught to regard him, have been Himself (as well as the Gods of Epicurus)¹ the result of the continued operation of the same blind causes? or rather, must not such a Being have necessarily resulted from these causes operating from all eternity, through the immensity of space?—a conclusion, by the way, which, according to Diderot's own principles, would lead us to refer the era of his origin to a period indefinitely more remote than any given point of time which imagination can assign; or, in other words, to a period to which the epithet *eternal* may with perfect propriety be applied. The amount, therefore, of the whole matter is this, that the atheistical reasoning, as stated by Diderot, leaves the subject of natural, and, I may add, of revealed religion, precisely on the same footing as before, without invalidating, in the very smallest degree, the evidence for any one of the doctrines connected with either; nay more, superadding to this evidence, a mathematical demonstration of the *possible* truth of all those articles of belief which it was the object of Diderot to subvert from their foundation.

It might be easily shown, that these principles, if pushed to their legitimate consequences, instead of establishing the just authority of reason in our constitution, would lead to the most unlimited credulity on all subjects whatever; or (what is only another name for the same thing) to that state of mind, which, in the words of Mr Hume, "does not consider any one proposition as more certain, or even as more probable, than another."

The following curious and (in my opinion) instructive anecdote has a sufficient connection with the subject of this note, to justify me in subjoining it to the foregoing observations. I transcribe it from the Notes annexed to the Abbé de Lille's poem, entitled *La Conversation*. (A Paris, 1812.)

"Dans la société du Baron d'Holbach, Diderot proposa un jour de nommer un *avocat de Dieu*, et on choisit l'Abbé Galiani. Il s'assit et débuta ainsi.

"Un jour à Naples, un homme de la Basilicate prit devant nous, six dés dans un cornet, et paria d'amener rasle de six. Je dis cette chance étoit possible. Il l'amena sur le champ une seconde fois; je dis la même chose. Il remit les dés dans le cornet trois, quatre, cinq fois, et toujours rasle de six. *Sangue di Bacco* m'écriai-je, *les dés sont pipés*; et ils l'étoient.

"Philosophes, quand je considère l'orde toujours renaissant de la nature, ses lois immuables, ses révolutions toujours constantes dans une variété infinie; cette chance unique et conservatrice d'un univers tel que nous le voyons, qui revient sans cesse, malgré cent autres millions de chances de perturbation et de destruction possibles, je m'écrie: *certes la nature est pipée!*"

The argument here stated strikes me as irresistible, nor ought it at all to weaken its effect, that it was spoken by the mouth of the Abbé Galiani. Of this extraordinary person I shall have occasion afterwards to speak as a political economist.

¹ *Cic. de Nat. Deor.* Lib. I. XXIV.

Whatever his own professed principles may have been, this theory of the *loaded die* appears evidently, from the repeated allusions to it in his familiar correspondence, to have produced a very deep impression on his mind. (See *Correspondance inédite de l'Abbé Galiani*, &c. Vol. I. pp. 18, 42, 141, 142, à Paris, 1818.)

As the old argument of the atomical atheists is plainly that on which the school of Diderot are still disposed to rest the strength of their cause, I shall make no apology for the length of this note. The sceptical suggestions on the same subject which occur in Mr Hume's *Essay on the Idea of Necessary Connection*, and which have given occasion to so much discussion in this country, do not seem to me to have ever produced any considerable impression on the French philosophers.

NOTE (CC.) p. 133.

AMONG the contemporaries of Diderot, the author of the *Spirit of Laws* is entitled to particular notice, for the respect with which he always speaks of natural religion. A remarkable instance of this occurs in a letter to Dr Warburton, occasioned by the publication of his *View of Bolingbroke's Philosophy*. The letter, it must be owned, savours somewhat of the political religionist; but how fortunate would it have been for France, if, during its late revolutionary governments, such sentiments as those here expressed by Montesquieu had been more generally prevalent among his countrymen! "Celui qui attaque la religion révélée n'attaque que la religion révélée; mais celui qui attaque la religion naturelle attaque toutes les religions du monde. . . . Il n'est pas impossible d'attaquer une religion révélée, parce qu'elle existe par des faits particuliers, et que les faits par leur nature peuvent être une matière de dispute; mais il n'en est pas de même de la religion naturelle; elle est tirée de la nature de l'homme, dont on ne peut pas disputer encore. J'ajoute à ceci, quel peut être le motif d'attaquer la religion révélée en Angleterre? On l'y a tellement purgé de tout préjugé destructeur qu'elle n'y peut faire de mal et qu'elle y peut faire, au contraire, une infinité de biens. Je sais, qu'un homme en Espagne ou en Portugal que l'on va brûler, ou qui craint d'être brûlé, parce qu'il ne croit point de certains articles dépendans ou non de la religion révélée, a un juste sujet de l'attaquer, parce qu'il peut avoir quelque espérance de pourvoir à sa défense naturelle: mais il n'en est pas de même en Angleterre, où tout homme qui attaque la religion révélée l'attaque sans intérêt, et où cet homme, quand il réussiroit, quand même il auroit raison dans le fond, ne feroit que détruire une infinité de biens pratiques, pour établir une vérité purement spéculative." (For the whole letter, see the 4th edit. of Montesquieu's *Works*. Paris, 1788. Tome V. p. 391. Also Warburton's *Works* by Hurd, Vol. VII. p. 553. London, 1758.)

In the foregoing passage, Montesquieu hints more explicitly than could well have been expected from a French magistrate, at a consideration which ought always to be taken into the account, in judging of the works of his countrymen, when they touch on the subject of religion; I mean, the corrupted and intolerant spirit of that system of faith which is immediately before their eyes. The eulogy bestowed on the church of England is particularly deserving of notice; and should serve as a caution to Protestant writers against making common cause with the defenders of the church of Rome.

With respect to Voltaire, who, amidst all his extravagancies and impieties, is well known to have declared open war against the principles maintained in the *Système de la Nature*, it is remarked by Madame de Staël, that two different epochs may be distinguished in his literary life; the one,

while his mind was warm from the philosophical lessons he had imbibed in England; the other, after it became infected with those extravagant principles which, soon after his death, brought a temporary reproach on the name of Philosophy. As the observation is extended by the very ingenious writer to the French nation in general, and draws a line between two classes of authors who are frequently confounded together in this country, I shall transcribe it in her own words.

“ Il me semble qu'on pourroit marquer dans le dix-huitième siècle, en France, deux époques parfaitement distinctes, celle dans laquelle l'influence de l'Angleterre s'est fait sentir, et celle où les esprits se sont précipités dans la destruction: Alors les lumières se sont changées en incendie, et la philosophie, magicienne irritée, a consumé le palais où elle avoit étalé ses prodiges.

“ En politique, Montesquieu appartient à la première époque, Raynal à la seconde; en religion les écrits de Voltaire, qui avoit la tolérance pour but, sont inspirés par l'esprit de la première moitié du siècle; mais sa misérable et vaniteuse irréligion a flétri la seconde.” (*De l'Allemagne*, Tome III. pp. 37, 38.)

Nothing, in truth, can be more striking than the contrast between the spirit of Voltaire's early and of his later productions. From the former may be quoted some of the sublimest sentiments any where to be found, both of religion and of morality. In some of the latter, he appears irrecoverably sunk in the abyss of fatalism. Examples of both are so numerous, that one is at a loss in the selection. In making choice of the following, I am guided chiefly by the comparative shortness of the passages.

“ Consulte Zoroastre et Minos, et Solon,
Et le sage Socrate, et le grand Cicéron :
Ils ont adoré tous un maître, un juge, un père ; —
Ce système sublime à l'homme est nécessaire.
C'est le sacré lien de la société,
Le premier fondement de la sainte équité ;
Le frein du scélérat, l'espérance du juste.
Si les cieux dépouillés de leur empreinte auguste
Pouvoient cesser jamais de le manifester,
Si Dieu n'existoit pas, il faudroit l'inventer.”¹

Nor is it only on this fundamental principle of religion that Voltaire, in his better days, delighted to enlarge. The existence of a natural law engraved on the human heart, and the liberty of the human will, are subjects which he has repeatedly enforced and adorned with all his philosophical and poetical powers. What can be more explicit, or more forcible, than the following exposition of the inconsistencies of fatalism?

“ Vois de la liberté cet ennemi mutin,
Aveugle partisan d'un aveugle destin ;
Entends comme il consulte, approuve, ou délibère,
Entends de quel reproche il couvre un adversaire,
Voy comment d'un rival il cherche à se venger,
Comme il punit son fils, et le veut corriger.

¹ A thought approaching very nearly to this occurs in one of Tillotson's Sermons. “ The being of God is so comfortable, so convenient, so necessary to the felicity of Mankind, that (as Tully admirably says), *Dil immortales ad usum hominum fabricati pene videantur*. — If God were not a necessary being of himself, he might almost be said to be made for the use and benefit of Man.” For some ingenious remarks on this quotation from Cicero, see Jortin's Tracts, Vol. I. p. 371.

Il le croyoit donc libre ?—Oui sans doute, et lui-même
 Dément à chaque pas son funeste système.
 Il mentoit à son cœur, en voulant expliquer
 Ce dogme absurde à croire, absurde à pratiquer.
 Il reconnoit en lui le sentiment qu'il brave,
 Il agit comme libre et parle comme esclave."

This very system, however, which Voltaire has here so severely reprobated, he lived to avow as the creed of his more advanced years. The words, indeed, are put into the mouth of a fictitious personage; but it is plain, that the writer meant to be understood as speaking his own sentiments. "Je vois une chaîne immense, dont tout est chaînon; elle embrasse, elle serre aujourd'hui la nature," &c. &c.

"Je suis donc ramené malgré moi à cette ancienne idée, que je vois être la base de tous les systèmes, dans laquelle tous les philosophes retombent après mille détours, et qui m'est démontré par toutes les actions des hommes, par les miennes, par tous les événemens que j'ai lus, que j'ai vus, et aux-quelles j'ai eu part; c'est le Fatalisme, c'est la Necessité dont je vous ai déjà parlé." (*Lettres de Memmius à Cicéron*. See *Œuvres de Voltaire, Mélanges*, Tome IV. p. 358. 4to. Edit. Geneve, 1771.)

Notwithstanding, however, this change in Voltaire's philosophical opinions, he continued to the last his zealous opposition to atheism.¹ But in what respects it is more pernicious than fatalism, it is not easy to discover.

A reflection of La Harpe's, occasioned by some strictures of Voltaire's upon Montesquieu, applies with equal force to the numberless inconsistencies which occur in his metaphysical speculations: "Les objets de méditation étoient trop étrangers à l'excessive vivacité de son esprit. Saisir fortement par l'imagination les objets qu'elle ne doit montrer que d'un côté, c'est ce qui est du Poète; les embrasser sous toutes les faces, c'est ce qui est du Philosophe, et Voltaire étoit trop exclusivement l'un pour être l'autre." (*Cours de Littérature*, Tome XV. pp. 46, 47.)

A late author² has very justly reprobated that *spiritual deification of nature* which has been long fashionable among the French; and which, according to his own account, is at present not unfashionable in Germany. It is proper, however, to observe, that this mode of speaking has been used by two very different classes of writers; by the one with an intention to keep as much as possible the Deity out of their view, while studying his works; by the other, as a convenient and well understood metaphor, by means of which the frequent and irreverent mention of the name of God is avoided in philosophical arguments. It was with this last view, undoubtedly, that it was so often employed by Newton, and other English philosophers of the same school. In general, when we find a writer speaking of the *wise* or of the *benevolent intentions* of nature, we should be slow in imputing to him any leaning towards atheism. Many of the finest instances of Final Causes, it is certain, which the eighteenth century has brought to light, have been first remarked by inquirers who seem to have been fond of this phraseology; and of these inquirers, it is possible that some would have been less forward in bearing testimony to the truth, had they been forced to avail themselves of the style of theologians. These speculations, therefore, concerning the *intentions* or *designs of Nature*, how reprehensible soever and even absurd in point of strict

¹ See the *Dict. Philosophique*, Art. *Athéisme*. See also the strictures on the *Système de la Nature* in the *Questions sur l'Encyclopédie*; the very work from which the above quotation is taken.

² Frederick Schlegel. *Lectures on the History of Literature*. Vol. II. p. 109. (Edinburgh, 1818.)

logic the language may be in which they are expressed, may often be, nay, have often been, a step towards something higher and better; and, at any rate, are of a character totally different from the blind chance of the Epicureans, or the conflicting principles of the Manicheans.

MORR (DD.) p. 153.

"In the attempt, indeed, which Kant has made to enumerate the general ideas which are not derived from experience, but arise out of the pure understanding, Kant may well lay claim to the praise of originality." The object of this problem is thus stated by his friend, Mr Schulze, the author of the Synopsis formerly quoted. (The following translation is by Dr Willich, *Elements*, &c. p. 45.)

"To investigate the whole store of original notions discoverable in our understanding, and which lie at the foundation of all our knowledge; and at the same time to authenticate their true descent, by showing that they are not derived from experience, but are pure productions of the understanding.

"1. The perceptions of objects contain, indeed, the matter of knowledge, but are in themselves blind and dead, and not knowledge; and our soul is merely passive in regard to them.

"2. If these perceptions are to furnish knowledge, the understanding must think of them, and this is possible only through notions (conceptions), which are the peculiar form of our understanding, in the same manner as space and time are the form of our sensitive faculty

"3. These notions are active representations of our understanding-faculty; and as they regard immediately the perceptions of objects, they refer to the objects themselves only mediately

"4. They lie on our understanding as pure notions *a priori*, at the foundation of all our knowledge. They are necessary forms, radical notions, categories (predicaments), of which all our knowledge of them must be compounded: And the table of them follows.

"Quantity; unity, plurality, totality.

"Quality; reality, negation, limitation.

"Relation; substance, cause, reciprocation.

"Modality; possibility, existence, necessity.

"5. Now, to think and to judge is the same thing; consequently, every notion contains a particular form of judgment concerning objects. There are four principal genera of judgments. They are derived from the above four possible functions of the understanding, each of which contains under it three species; namely, with respect to

"Quantity, they are universal, particular, singular judgments.

"Quality, they are affirmative, negative, infinite judgments.

"Relation, they are categorical, hypothetical, disjunctive judgments.

"Modality, they are problematical, assertory, apodictical judgments."

These tables speak for themselves without any comment.

NOTE (EE.) p. 154.

KANT'S notions of Time are contained in the following seven propositions: "1. *Idea temporis non oritur sed supponitur a sensibus.* 2. *Idea temporis est singularis, non generalis.* Tempus enim

quodlibet non cogitatur, nisi tanquam pars unius ejusdem temporis immensi. 3. *Idea itaque temporis est intuitus*, et quoniam ante omnem sensationem concipitur, tanquam conditio respectuum in sensibilibus obviorem, est *intuitus*, non sensualis, sed *purus*. 4. *Tempus est quantum continuum* et legum continui in mutationibus universi principium. 5. *Tempus non est objectivum aliquid et reale*, nec substantia, nec accidens, nec relatio, sed *subjectiva conditio*, per naturam mentis humanæ necessaria, quælibet sensibilia, certa lege sibi co-ordinandi, et *intuitus purus*. 6. *Tempus est conceptus verissimus*, et, per omnia possibilia sensuum objecta, in infinitum patens, intuitivæ representationis conditio. 7. *Tempus itaque est principium formale mundi sensibilis absolute primum.*"

With respect to *Space*, Kant states a series of similar propositions, ascribing to it very nearly the same metaphysical attributes as to *Time*, and running as far as possible a sort of parallel between them. "A. *Conceptus spatii non abstrahitur a sensationibus externis*. B. *Conceptus spatii est singularis representatio omnia in se comprehendens*, non *sub se* continens notio abstracta et communis. C. *Conceptus spatii itaque est intuitus purus*; cum sit conceptus singularis; sensationibus non conflatus, sed omnis sensationis externæ forma fundamentalis. D. *Spatium non est aliquid objectivi et realis*, nec substantia, nec accidens, nec relatio; sed *subjectivum et ideale*, e natura mentis stabili lege proficiscens, veluti schema, omnia omnino externe sensa sibi co-ordinandi. E. *Quamquam conceptus spatii*, ut objectivi alicujus et realis entis vel affectionis, sit imaginarius, nihilo tamen secius *respective ad sensibilia quæcunque*, non solum est *verissimus*, sed et omnis veritatis in sensualitate externa fundamentum."

These propositions are extracted from a Dissertation written by Kant himself in the Latin language.¹ Their obscurity, therefore, cannot be ascribed to any misapprehension on the part of a translator. It was on this account that I thought it better to quote them in his own unaltered words, than to avail myself of the corresponding passage in Born's Latin version of the *Critique of Pure Reason*.

To each of Kant's propositions concerning Time and Space I shall subjoin a short comment, following the same order in which these propositions are arranged above.

1. That the idea of *Time* has no resemblance to any of our sensations, and that it is, therefore, not derived from sensation immediately and directly, has been very often observed; and, if nobody had ever observed it, the fact is so very obvious, that the enunciation of it could not entitle the author to the praise of much ingenuity. Whether "this idea be *supposed* in all our sensations," or (as Kant explains himself more clearly in his third proposition) "be *conceived* by the mind prior to all sensation," is a question which seems to me at least doubtful; nor do I think the opinion we form concerning it a matter of the smallest importance. One thing is certain, that this idea is an inseparable concomitant of every act of memory with respect to past events; and that, in whatever way it is acquired, we are irresistibly led to ascribe to the thing itself an existence independent of the will of any being whatever.

2. On the second proposition I have nothing to remark. The following is the most intelligible translation of it that I can give. "The idea of Time is singular, not general; for any particular length of time can be conceived only as a part of one and the same immense whole."

3. From these premises (such as they are) Kant concludes, that the idea of Time is *intuitive*; and that this intuition, being prior to the exercise of the senses, is not empirical but pure. The

¹ *De Mundi Sensibilis atque Intelligibilis forma et principis*. Dissertatio pro loco professionis Log. et Metaph. Ordinarius rite sibi vindicando; quam exigentibus statutis Academicis publice tubitur IMMANUEL KANT.—Regiomonti, 1770.

conclusion here must necessarily partake of the uncertainty of the premises from which it is drawn, but the meaning of the author does not seem to imply any very erroneous principle. It amounts, indeed, to little more than an explanation of some of his peculiar terms.

4. That Time is a *continued quantity* is indisputable. To the latter clause of the sentence I can annex no meaning but this, that time enters as an essential element into our conception of the law of continuity, in all its various applications to the changes that take place in Nature.

5. In this proposition Kant assumes the truth of that much contested, and, to me, incomprehensible doctrine, which denies the objective reality of time. He seems to consider it merely as a subjective condition, inseparably connected with the frame of the Human Mind, in consequence of which it arranges sensible phenomena, according to a certain law, in the order of succession.

6. What is meant by calling Time a *true conception*, I do not profess to understand; nor am I able to interpret the remainder of the sentence in any way but this, that we can find no limits to the range thus opened in our conceptions to the succession of sensible events.

7. The conclusion of the whole matter is, that Time is "absolutely the first formal principle of the sensible world." I can annex no meaning to this; but I have translated the original, word for word, and shall leave my readers to their own conjectures.

A. It appears from this, that, in the opinion of Kant, the idea of Space is connate with the mind, or, at least, that it is prior to any information received from the senses. But this doctrine seems to me not a little doubtful. Indeed, I rather lean to the common theory, which supposes our first ideas of Space or Extension to be formed by abstracting this attribute from the other qualities of matter. The idea of Space, however, in whatever manner formed, is manifestly accompanied with an irresistible conviction, that Space is necessarily existent, and that its annihilation is impossible; nay, it appears to me to be also accompanied with an irresistible conviction, that Space cannot possibly be extended in more than three dimensions. Call either of these propositions in question, and you open a door to universal scepticism.

B. I can extract no meaning from this, but the nugatory proposition, that our conception of Space leads us to consider it as the place in which all things are comprehended.

C. "The conception of Space, therefore, is a *pure intuition*." This follows as a necessary corollary (according to Kant's own definition) from Prop. A. What is to be understood by the clause which asserts, that Space is the fundamental form of every external sensation, it is not easy to conjecture. Does it imply merely that the conception of Space is necessarily involved in all our notions of things external? In this case, it only repeats over, in different and most inaccurate terms, the last clause of Prop. B. What can be more loose and illogical than the phrase *external sensation*?

D. That Space is neither a *substance*, nor an *accident*, nor a *relation*, may be safely granted; but does it follow from this that it is nothing *objective*, or, in other words, that it is a mere creature of the imagination? This, however, would seem to be the idea of Kant; and yet I cannot reconcile it with what he says in Prop. E., that the conception of Space is the foundation of all the truth we ascribe to our perceptions of external objects. (The author's own words are—*omnis veritatis in sensualitate externa fundamentum*!)

¹ Mr Nitch has remarked this difficulty, and has attempted to remove it. "The most essential objection (he observes) to Kant's system is, that it leads to scepticism; because it maintains, that the figures in which we see the external objects clothed are not in-

Upon the whole, it appears to me, that, among these various propositions, there are some which are quite unintelligible; that others assume, as first principles, doctrines which have been disputed by many of our most eminent philosophers; that others, again, seem to aim at involving plain and obvious truths in darkness and mystery; and that not one is expressed with the simplicity and precision which are the natural results of clear and accurate thinking. In considering time and space as the *forms* of all sensible phenomena, does Kant mean any thing more but this,—that we necessarily refer every sensible phenomenon to some point of space, or to some instant of time? If this was really his meaning, he has only repeated over, in obscurer language, the following propositions of Newton: “*Ut ordo partium temporis est immutabilis, sic etiam ordo partium spatii. Moveantur hæc de locis suis, et movebuntur (ut ita dicam) de seipais. Nam tempora et spatia sunt sui ipsorum et rerum omnium quasi loca. In tempore, quoad ordinem successionis; in spatio, quoad ordinem situs locantur universa. De illorum essentia est ut sint loca: et loca primaria moveri absurdum est*”

I have quoted this passage, not from any desire of displaying the superiority of Newton over Kant, but chiefly to show how very nearly the powers of the former sink to the same level with those of the latter, when directed to inquiries unfathomable by the human faculties. What abuse of words can be greater than to say, That neither the parts of time nor the parts of space can be moved from their *places*?¹ In the *Principia* of Newton, however, this incidental discussion is but a spot on the sun. In the *Critique of Pure Reason*, it is a fair specimen of the rest of the work, and forms one of the chief pillars of the whole system, both metaphysical and moral.

NOTE (FF.) p. 155.

THE following quotation will account for the references which I have made to Mr. Nitsch among the expounders of Kant's Philosophy. It will also serve to show that the *Critique of Pure Reason* has still some admirers in England, not less enthusiastic than those it had formerly in Germany.

“In submitting this fourth Treatise on the Philosophy of Kant to the reader” (says the author of these articles in the *Encyclopædia Londinensis*), “I cannot deny myself the satisfaction of publicly acknowledging the great assistance which I have derived in my literary pursuits, from my excellent and highly valued friend Mr Henry Richter. To him I am indebted for the clearness and perspicuity with which the thoughts of the immortal Kant have been conveyed to the public. Indeed, his comprehensive knowledge of the system, as well as his enthusiastic admiration of its general truth, render him a most able and desirable co-operator. Should, therefore, any good result to mankind from our joint labours in the display of this vast and profound system, he is justly entitled to his share of the praise. It is with sincere pleasure that I reflect upon that period, now

herent in those objects, and that consequently space is something *within*, and not *without* the mind.” (pp. 144, 145.) “It may be farther objected (he adds), that, if there be no external space, there is also no external world. But, this is concluding by far too much from these premises. If there be no external space, it will follow, that we are not authorised to assign *extension* to external things, but there will follow no more.” (p. 140.) Mr Nitsch then proceeds to obviate these objections; but his reply is far from satisfactory, and is indeed not less applicable to the doctrine of Berkeley than to that of Kant. This point, however, I do not mean to argue here. The concessions which Nitsch has made are quite sufficient for my present purpose. They serve at least to satisfy my own mind, that I have not misrepresented Kant's meaning.

¹ Was it not to avoid the palpable incongruity of this language that Kant was led to substitute the word *forms* instead of *places*; the former word not seeming to be so obviously inapplicable as the latter to time and space in common; or, to speak more correctly, being, from its extreme vagueness, equally unmeaning when applied to both?

two and twenty years ago, when we first studied together under the same master, Frederic Augustus Nitsch, who originally imported the seeds of TRANSCENDENTAL PHILOSOPHY from its native country, to plant them in our soil; and though, as is usually the case, many of those seeds were scattered by the wind, I trust that a sufficient number have taken root to maintain the growth of this vigorous and flourishing plant, till the time shall come, when, by its general cultivation, England may be enabled to enrich other nations with the most perfect specimens of its produce. Professor Nitsch, who thus bestowed upon our country his first attainments in the department of *Pure Science*, has paid the debt of nature. I confess it is some reflection upon England, that she did not foster and protect this immediate disciple of the father of philosophy; but the necessities of this learned and illustrious man unfortunately compelled him to seek that subsistence elsewhere, which was withheld from him here. At Rostock, about the year 1813, this valuable member of society, and perfect master of the philosophy he undertook to teach, entered upon his immortal career as a reward for his earthly services. It is with the most heartfelt satisfaction that I add my mite of praise to his revered memory. But for him, I might ever have remained in the dark regions of sophistry and uncertainty."

NOTZ (G.G.) p. 164.

AMONG the secondary mischiefs resulting from the temporary popularity of Kant, none is more to be regretted than the influence of his works on the habits, both of thinking and of writing, of some very eminent men, who have since given to the world histories of philosophy. That of Tenneman in particular (a work said to possess great merit) would appear to have been vitiated by this unfortunate bias in the views of its author. A very competent judge has lately said of it, that "it affords, as far as it is completed, the most accurate, the most minute, and the most rational view we yet possess of the different systems of philosophy; but that the critical philosophy being chosen as the vantage ground from whence the survey of former systems is taken, the continual reference in Kant's own language to his peculiar doctrines, renders it frequently impossible for those who have not studied the dark works of this modern Heraclitus to understand the strictures of the historian on the systems even of Aristotle or Plato."* (See the article BRUCKER in this *Supplement*.) We are told by the same writer, that "among the learned of Germany, Brucker has never enjoyed a very distinguished reputation." This I can very easily credit; but I am more inclined to interpret it to the disadvantage of the German taste, than to that of the historian. Brucker is indeed not distinguished by any extraordinary measure of depth or of acuteness; but in industry, fidelity, and sound judgment, he has few superiors; qualities of infinitely greater value in the undertaker of a historical work, than that passion for systematical refinement, which is so apt to betray the best-intentioned writers into false glosses on the opinions they record.

When the above passage was written, I had not seen the work of Buhle. I have since had an opportunity of looking into the French translation of it, published at Paris in 1816; and I must frankly acknowledge, that I have seldom met with a greater disappointment. The account there given of the Kantish system, to which I turned with peculiar eagerness, has, if possible, involved to my apprehension, in additional obscurity, that mysterious doctrine. From this, however, I did not feel myself entitled to form an estimate of the author's merits as a philosophical historian, till I had read some other articles of which I considered myself as better qualified to judge.

The following short extract will, without the aid of any comment, enable such of my readers as know anything of the literary history of Scotland, to form an opinion upon this point for themselves.

"Reid n'attaqua les systèmes de ces prédécesseurs, et notamment celui de Hume, que parce qu'il se croyait convaincu de leur défaut de fondement. Mais un autre antagoniste, non moins célèbre, du scepticisme de Hume, fut, en outre, guidé par la haine qu'il avoit vouée à son illustre compatriote, lequel lui répondit avec beaucoup d'aigreur et d'amertume. James Beattie, professeur de morale à Edimbourg, puis ensuite, de logique et de morale, à l'Université d'Aberdeen, obtint la préférence sur Hume lorsqu'il fut question de remplir la chaire vacante à Edimbourg. Cette circonstance étant sans doute la principale source de l'inimitié que les deux savans conquirent l'un pour l'autre, et qui influa même sur le ton qu'ils employèrent dans les raisonnemens par lesquels ils se combattirent." (Tome V. p. 235.)

To this quotation may I be pardoned for adding a few sentences relative to myself? "L'ouvrage de Dugald Stewart, intitulé, *Elements of the Philosophy of the Human Mind*, est un syncrétisme des opinions de Hartley et de Reid. Stewart borne absolument la connoissance, tant de l'âme que des choses extérieures, à ce que le sens commun nous en apprend, et croit pouvoir ainsi mettre l'étude de la métaphysique à l'abri du reproche de rouler sur des choses qui dépassent la sphère de notre intelligence, ou qui sont tout-à-fait inutiles dans la pratique de la vie. . . . Les chapitres suivans renferment le développement du principe de l'association des idées. Ils sont presque entièrement écrits d'après Hartley. Stewart fait dériver de ce principe toutes les facultés intellectuelles et pratiques de l'homme." (Tom. V. pp. 330, 331.)

Of the discrimination displayed by Buhle in the classification of systems and of authors, the title prefixed to his 19th chapter may serve as a specimen: "*Philosophy of Condillac, of Helvetius, of Baron d'Holbach, of Robinet, of Bonnet, of Montesquieu, of Burlamaqui, of Vattel, and of Reid.*"

But the radical defect of Buhle's work is, the almost total want of references to original authors. We are presented only with the general results of the author's reading, without any guide to assist us in confirming his conclusions when right, or in correcting them when wrong. This circumstance is of itself sufficient to annihilate the value of any historical composition.

Sismondi, in mentioning the history of modern literature by Bouterwek, takes occasion to pay a compliment (and, I have no doubt, a very deserved one) to German scholars in general; observing, that he has executed his task—"avec une étendue d'érudition, et une loyauté dans la manière d'en faire profiter ses lecteurs, qui semblent propres aux savans Allemands." (*De la Litt. du Midi de l'Europe*, Tom. I. p. 13, à Paris, 1813.) I regret that my ignorance of the German language has prevented me from profiting by a work of which Sismondi has expressed so favourable an opinion; and still more, that the only history of philosophy from the pen of a contemporary German scholar, which I have had access to consult, should form so remarkable an exception to Sismondi's observation.

The contents of the preceding note lay me under the necessity, in justice to myself, of taking some notice of the following remark on the first part of this *Dissertation*, by an anonymous critic. (See *Quarterly Review*, Vol. XVII. p. 42.)

"In the plan which Mr Stewart has adopted, if he has not consulted his strength, he has at least consulted his ease; for, supposing a person to have the requisite talent and information, the task which our author has performed, is one which, with the historical abstracts of Buhle or Tenneman, cannot be supposed to have required any very laborious meditation."

On the insinuation contained in the foregoing passage, I abstain from offering any comment. I have only to say, that it is now, for the first time (Summer of 1820), that I have seen the work of Burke; and that I have never yet had an opportunity of seeing that of Tenneman. From what I have found in the one, and from what I have heard of the other, I am strongly inclined to suspect, that when the anonymous critic wrote the above sentence, he was not less ignorant than myself of the works of these two historians. Nor can I refrain from adding (which I do with perfect confidence), that no person competent to judge on such a subject can read with attention this Historical Sketch, without perceiving that its merits and defects, whatever they may be, are at least all my own.

NOTE (HH.) p. 168.

OF the Scottish authors who turned their attention to metaphysical studies, prior to the Union of the two Kingdoms, I know of none so eminent as George Dalgarno of Aberdeen, author of two works, both of them strongly marked with sound philosophy, as well as with original genius. The one published at London, 1660, is entitled, "*Ars signorum, vulgò character universalis et lingua philosophica, qua poterunt, homines diversissimorum idiomatum, spatio duarum septimanarum, omnia animi sui sensa (in rebus familiaribus) non minus intelligibiliter, sive scribendo, sive loquendo, mutuo communicare, quam linguis propriis vernaculis. Præterea, hinc etiam poterunt juvenes philosophiæ principia, et veram logicæ praxin, citius et facilius multo imbibere, quam ex vulgaribus philosophorum scriptis.*" The other work of Dalgarno, is entitled, "*Didascalocophus, or the Deaf and Dumb Man's Tutor.*" Printed at Oxford, 1680. I have given some account of the former in the notes at the end of the first volume of the *Philosophy of the Human Mind*; and of the latter, in a *Memoir*, published in Vol. VII. of the *Transactions of the Royal Society of Edinburgh*. As they are now become extremely rare, and would together form a very small octavo volume, I cannot help thinking that a bookseller, who should reprint them, would be fully indemnified by the sale. The fate of Dalgarno will be hard, indeed, if, in addition to the unjust neglect he experienced from his contemporaries, the proofs he has left of his philosophical talents shall be suffered to sink into total oblivion.

Lord Stair's *Physiologia Nova Experimentalis* (published at Leyden in 1686) is also worthy of notice in the literary history of Scotland. Although it bears few marks of the eminent talents which distinguished the author, both as a lawyer and as a statesman, it discovers a very extensive acquaintance with the metaphysical as well as with the physical doctrines, which were chiefly in vogue at that period; more particularly with the leading doctrines of Gassendi, Descartes, and Malebranche. Many acute and some important strictures are made on the errors of all the three, and at the same time complete justice is done to their merits; the writer every where manifesting an independence of opinion and a spirit of free inquiry, very uncommon among the philosophers of the seventeenth century. The work is dedicated to the Royal Society of London, of the utility of which institution, in promoting experimental knowledge, he appears to have been fully aware.

The limit of a note will not permit me to enter into farther details concerning the state of philosophy in Scotland, during the interval between the Union of the Crowns and that of the Kingdoms. The circumstances of the country were indeed peculiarly unfavourable to it. But memorials still exist of a few individuals, sufficient to show, that the philosophical taste, which has so remarkably distinguished our countrymen during the eighteenth century, was in some measure an inheritance from their immediate predecessors. Leibnitz, I think, somewhere mentions the number of learned

Scotchmen by whom he was visited in the course of their travels. To one of them (Mr. Burnet of Kemney) he has addressed a most interesting letter, dated in 1697, on the general state of learning and science in Europe; opening his mind on the various topics which he introduces, with a freedom and confidence highly honourable to the attainments and character of his correspondent. Dr Arbuthnot, who was born about the time of the Restoration, may serve as a fair specimen of the very liberal education which was then to be had in some of the Scottish Universities. The large share which he is allowed to have contributed to the *Memoirs of Martinus Scriblerus* abundantly attests the variety of his learning, and the just estimate he had formed of the philosophy of the schools; and in one or two passages, where he glances at the errors of his contemporaries, an attentive and intelligent reader will trace, amid all his pleasantry, a metaphysical depth and soundness which seem to belong to a later period.—Is there no Arbuthnot now, to chastise the follies of our craniologists?

NOTE (II.) p. 184.

THE letter which gives occasion to this note was written twenty years after the publication of the *Treatise of Human Nature*. As it relates, however, to the history of Mr Hume's studies previous to that publication, I consider this as the proper place for introducing it. The Dialogue to which the letter refers was plainly that which appeared after Mr Hume's death, under the title of *Dialogues on Natural Religion*.

“ DEAR SIR,

Ninewells, March 19, 1751

“ You would perceive by the sample I have given you, that I make Cleanthes the hero of the dialogue. Whatever you can think of to strengthen that side of the argument will be most acceptable to me. Any propensity you imagine I have to the other side crept in upon me against my will; and it is not long ago that I burned an old manuscript book, wrote before I was twenty, which contained, page after page, the gradual progress of my thoughts on that head. It began with an anxious search after arguments to confirm the common opinion; doubts stole in, dissipated, returned, were again dissipated, returned again, and it was a perpetual struggle of a restless imagination against inclination, perhaps against reason.

“ I have often thought that the best way of composing a dialogue would be for two persons that are of different opinions about any question of importance, to write alternately the different parts of the discourse, and reply to each other. By this means that vulgar error would be avoided of putting nothing but nonsense into the mouth of the adversary; and, at the same time, a variety of character and genius being upheld, would make the whole look more natural and unaffected. Had it been my good fortune to live near you, I should have taken on me the character of Philo in the dialogue, which you'll own I could have supported naturally enough; and you would not have been averse to that of Cleanthes. I believe, too, we could both of us have kept our tempers very well; only you have not reached an absolute philosophical indifference on these points. What danger can ever come from ingenious reasoning and inquiry? The worst speculative sceptic ever I knew was a much better man than the best superstitious devotee and bigot. I must inform you, too, that this was the way of thinking of the ancients on this subject. If a man made profession of philosophy, whatever his sect was, they always expected to find more regularity in his life and manners than in those of the ignorant and illiterate. There is a remarkable pas-

sage of Appian to this purpose. That historian observes, that, notwithstanding the established prepossessions in favour of learning, yet some philosophers who have been trusted with absolute power have very much abused it; and he instances Critias, the most violent of the Thirty, and Aristion who governed Athens in the time of Sylla. But I find, upon inquiry, that Critias was a professed Atheist, and Aristion an Epicurean, which is little or nothing different; and yet Appian wonders at their corruption as much as if they had been Stoics or Platonists. A modern zealot would have thought that corruption unavoidable.

"I could wish that Cleanthes's argument could be so analyzed as to be rendered quite formal and regular. The propensity of the mind towards it, unless that propensity were as strong and universal as that to believe in our senses and experience, will still, I am afraid, be esteemed a suspicious foundation. 'Tis here I wish for your assistance. We must endeavour to prove that this propensity is somewhat different from our inclination to find our own figures in the clouds, our face in the moon, our passions and sentiments even in inanimate matter. Such an inclination may and ought to be controlled, and can never be a legitimate ground of assent.

"The instances I have chosen for Cleanthes are, I hope, tolerably happy; and the confusion in which I represent the sceptic seems natural. But, *si quid novisti rectius*, &c.

"You ask me, if the idea of cause and effect is nothing but vicinity? (you should have said constant vicinity or regular conjunction)—I would gladly know whence is that farther idea of causation against which you argue? The question is pertinent; but I hope I have answered it. We feel, after the constant conjunction, an easy transition from one idea to the other, or a connection in the imagination; and, as it is usual for us to transfer our own feelings to the objects on which they are dependant, we attach the internal sentiment to the external objects. If no single instances of cause and effect appear to have any connection, but only repeated similar ones, you will find yourself obliged to have recourse to this theory.

"I am sorry our correspondence should lead us into these abstract speculations. I have thought, and read, and composed very little on such questions of late. Morals, politics, and literature, have employed all my time; but still the other topics I must think more curious, important, entertaining, and useful, than any geometry that is deeper than Euclid. If, in order to answer the doubts started, new principles of philosophy must be laid, are not these doubts themselves very useful? Are they not preferable to blind and ignorant assent? I hope I can answer my own doubts: but, if I could not, is it to be wondered at? To give myself airs and speak magnificently; might I not observe that Columbus did not conquer empires and plant colonies?

"If I have not unravelled the knot so well in these last papers I sent you, as perhaps I did in the former, it has not, I assure you, proceeded from want of good will. But some subjects are easier than others; and sometimes one is happier in one's researches and inquiries than at other times. Still I have recourse to the *si quid novisti rectius*; not in order to pay you a compliment, but from a real philosophical doubt and curiosity."¹

An unfinished draught of the letter, to which the foregoing seems to have been the reply, has been preserved among Sir Gilbert Elliot's papers. This careless fragment is in his own handwriting, and exhibits an interesting specimen of the progress made in Scotland among the higher classes, seventy years ago, not only in sound philosophy, but in purity of English style.

¹ The original is in the possession of the Earl of Minto.

" DEAR SIR,

" Inclosed I return your papers, which, since my coming to town, I have again read over with the greatest care. The thoughts which this last perusal of them has suggested I shall set down, merely in compliance with your desire, for I pretend not to say anything new upon a question which has already been examined so often and so accurately. I must freely own to you, that to me it appears extremely doubtful, if the position which Cleanthes undertakes to maintain can be supported, at least in any satisfactory manner, upon the principles he establishes and the concessions he makes. If it be only from effects exactly similar that experience warrants us to infer a similar cause, then I am afraid it must be granted, that the works of Nature resemble not so nearly the productions of man as to support the conclusion which Cleanthes admits can be built only on that resemblance. The two instances he brings to illustrate his argument are indeed ingenious and elegant; the first, especially, which seemingly carries great weight along with it: the other, I mean that of the Vegetating Library, as it is of more difficult apprehension, so I think it is not easy for the mind either to retain or to apply it. But, if I mistake not, this strong objection strikes equally against them both. Cleanthes does no more than substitute two artificial instances in the place of natural ones: but if these bear no nearer a resemblance than natural ones to the effects which we have experienced to proceed from men, then nothing can justly be inferred from them; and if this resemblance be greater, then nothing farther ought to be inferred from them. In one respect, however, Cleanthes seems to limit his reasonings more than is necessary even upon his own principles. Admitting, for once, that experience is the only source of our knowledge, I cannot see how it follows, that, to enable us to infer a similar cause, the effects must not only be similar, but exactly and precisely so. Will not experience authorise me to conclude, that a machine or a piece of mechanism was produced by human art, unless I have happened previously to see a machine or piece of mechanism exactly of the same sort? Point out, for instance, the contrivance and end of a watch to a peasant, who had never before seen anything more curious than the coarsest instruments of husbandry, will he not immediately conclude, that this watch is an effect produced by human art and design? And I would still farther ask, does a spade or a plough much more resemble a watch than a watch does an organized animal? The result of our whole experience, if experience indeed be the only principle, seems rather to amount to this: There are but two ways in which we have ever observed the different parcels of matter to be thrown together; either at random, or with design and purpose. By the first, we have never seen produced a regular complicated effect, corresponding to a certain end; by the second, we uniformly have. If, then, the works of nature, and the productions of man, resemble each other in this one general characteristic, will not even experience sufficiently warrant us to ascribe to both a similar though proportionable cause? If you answer, that abstracting from the experience we acquire in this world, order and adjustment of parts is no proof of design, my reply is, that no conclusions, drawn from the nature of so chimerical a being as man, considered abstracted from experience, can at all be listened to. The principles of the human mind are clearly so contrived as not to unfold themselves till the proper objects and proper opportunity and occasion be presented. There is no arguing upon the nature of man but by considering him as grown to maturity, placed in society, and become acquainted with surrounding objects. But if you should still farther urge, that, with regard to instances of which we have no experience, for ought we know, matter may contain the principles of order, arrangement, and the adjustment of final causes, I should only answer, that whoever can conceive this proposition to be true, has exactly the same idea of matter that I have of mind. I know not if I have reasoned justly upon Cleanthes's prin-

ciples, nor is it indeed very material. The purpose of my letter is barely to point out what to me appears the fair and philosophical method of proceeding in this inquiry. That this universe is the effect of an intelligent designing cause, is a principle which has been most universally received in all ages and in all nations; the proof uniformly appealed to is, the admirable order and adjustment of the works of nature. To proceed, then, experimentally and philosophically, the first question in point of order seems to be, what is the effect which the contemplation of the universe, and the several parts of it, produces upon a considering mind? This is a question of fact; a popular question, the discussion of which depends not upon refinements and subtlety, but merely upon impartiality and attention. I ask, then, what is the sentiment which prevails in one's mind, after having considered not only the more familiar objects that surround him, but also all the discoveries of Natural Philosophy and Natural History; after having considered not only the general economy of the universe, but also the most minute parts of it, and the amazing adjustment of means to ends with a precision unknown to human art, and in instances innumerable? Tell me (to use the words of Cleanthes), does not the idea of a Contriver flow in upon you with a force like that of sensation? Expressions how just! (yet in the mouth of Cleanthes you must allow me to doubt of their propriety.) Nor does this conviction only arise from the consideration of the inanimate parts of the creation, but still more strongly from the contemplation of the faculties of the understanding, the affections of the heart, and the various instincts discoverable both in men and brutes; all so properly adapted to the circumstances and situation both of the species and the individual. Yet this last observation, whatever may be in it, derives no force from experience. For who ever saw a mind produced? If we are desirous to push our experiments still farther, and inquire, whether the survey of the universe has regularly and uniformly led to the belief of an intelligent cause? Shall we not find, that, from the author of the book of Job to the preachers at Boyle's Lecture, the same language has been universally held? No writer, who has ever treated this subject, but has either applied himself to describe, in the most emphatical language, the beauty and order of the universe, or else to collect together and place in the most striking light, the many instances of contrivance and design which have been discovered by observation and experiment. And when they have done this, they seem to have imagined that their task was finished, and their demonstration complete; and indeed no wonder,—for it seems to me, that we are scarce more assured of our own existence, than that this well-ordered universe is the effect of an intelligent cause.

“ This first question, then, which is indeed a question of fact, being thus settled upon observations which are obvious and unrefined, but not on that account the less satisfactory, it becomes the business of the philosopher to inquire, whether the conviction arising from these observations be founded on the conclusions of reason, the reports of experience, or the dictates of feeling, or possibly upon all these together; but if his principles shall not be laid so wide as to account for the fact already established upon prior evidence, we may, I think, safely conclude, that his principles are erroneous. Should a philosopher pretend to demonstrate to me, by a system of optics, that I can only discern an object when placed directly opposite to my eye, I should certainly answer, your system must be defective, for it is contradicted by matter of fact.” * * * * *

When this *Dissertation* was nearly ready for the press, the posthumous works of my late very learned, ingenious, and amiable friend, Dr Thomas Brown, were published. The contributions which the philosophy of the human mind owes to his talents and industry, belong exclusively to the literary history of the nineteenth century; and will, I doubt not, receive ample justice from the pens of some of his numerous pupils. On certain points on which we differed in opinion, more particularly on the philosophical merits of Lord Bacon and of Dr Reid, I should have been tempted to offer some additional explanations, if the circumstance of his recent and much lamented death had not imposed silence on me, upon all questions of controversy between us. The state of my health, besides, has been such during the winter, that I have found the task of correcting the press more than sufficient to furnish employment both to my mind and body; and, in fact, I have been forced to deny myself the satisfaction of reading Dr Brown's *Lectures*, till my own performance shall be in the hands of the public.

THE END.

Supplement

TO THE

ENCYCLOPÆDIA BRITANNICA.

H U N

HUNGARY, one of the kingdoms comprehended within the empire of Austria, and the constitution of which is, in some degree, sketched under that article, in the Second Volume of this *Supplement*.

It is wholly surrounded by other Austrian states, and bounded on the east by the district of the Seven Mountains, on the north-east by Galicia, on the north-west by Moravia, on the south-west by Illyria, on the west by Steyermark, and on the south by the military colonies. Its extent is variously estimated by different writers, some making it not more than 86,060 square English miles; whilst Lipsky, the latest geographer, calculates it at 88,940 miles. The whole kingdom lies between the latitude $44^{\circ} 2'$, and $49^{\circ} 46' 20''$ north, and between longitude $16^{\circ} 12'$ and $25^{\circ} 16'$ east from London. The Austrian province of Hungary is more extensive than the kingdom of that name, and includes within it the principalities of the Seven Mountains, the military boundaries, and the lands of Dalmatia; but they are not regulated according to the constitution of the kingdom of Hungary, but governed directly by the cabinet of Vienna, with the intervention of the Governor-general of the province.

The kingdom of Hungary, properly so called, is divided into six circles, the names, extent, and population of which are as follows:

Extent in English Square Miles.	Population in 1805.
1. Circle this side the Danube, 23,595	2,194,390
2. Circle beyond the Danube, 16,896	1,062,270
3. Circle this side the Theisa, 15,510	1,442,626
4. Circle beyond the Theisa, 26,946	1,919,284
5. Province of Slavonia, 3,570	287,868
6. Province of Croatia, 2,262	200,820
88,779	7,707,258

The number of the people here given is that of the conscription lists of 1805, in which the nobility and clergy were not included. The former of those bodies amounted, according to a list twenty years before, to 13,728, and the latter to 162,49. males; so that, estimating the females of noble families at the same number, and that neither they nor the clergy had increased or diminished in the preceding twenty years, the whole population in 1805 must have been 8,105,950. In the period that has elapsed since the census was made, an increase must have taken place, as the country has not been the seat of war; and though many of its male population must have fallen in the wide spreading hostilities between Austria and France, the country has been exposed to no such calamitous visitations as tend greatly to check the increase of population. Blumenbach estimated the

Hungary. number of inhabitants in 1817 to be 8,500,000; and Lichternstern, another statistical writer of great accuracy, coincides with his calculation. By the conscription lists of 1805, the numbers of the sexes appeared to be more nearly equal than is generally found to be the case. The males were 3,759,526, and the females 3,796,394.

Religion
and Edu-
cation.

The majority of the people are Catholics, but the other religious sects are established upon nearly a footing of equality, and have their independent ecclesiastical revenues and discipline. In 1805, the Catholics, including some of the Greek church, and the Armenians who had united with them, were 4,647,832. The Greek church, separate from the Catholics, were 1,161,138, the Calvinists, or Reformed, 1,002,490, the Lutherans 624,776, and the Jews 75,128. The Catholic hierarchy consists of three Archbishops, seventeen diocesan and nineteen titular Bishops; besides Abbots, Priors, and other dignified clergy. The Greek church has one Archbishop, seven Bishops, eighteen Deans, several Abbots, and near three thousand Parish Priests. The Reformed have, in four superintendencies, thirteen hundred ministers; and the Lutherans, in four superintendencies, four hundred and eighty pastors. The education of the people is carefully attended to, as far as regards elementary instruction. Each of the religious sects have their separate institutions for educating those of their confession. The Catholics control one University, five Academies, one Lyceum, two Philosophical Institutes, fifty-five Gymnasiums, six Grammar schools, and nine schools for preparing teachers for the villages, whose number is two thousand six hundred and ninety, and employ three thousand five hundred teachers. The Greeks in union with the Catholics have three hundred and eighty schools, and the same number of teachers. The independent Greeks have two gymnasiums, and twelve hundred and thirty schools, with a master to each. The Reformed have three Colleges, six Gymnasiums, and sixteen hundred schools. The Lutherans have one Lyceum, one College, ten Gymnasiums, and six hundred and thirty schools, with a teacher to each. Thus, for about eight millions and a half of people, the number of institutions for the instruction of the young amount to upwards of six thousand six hundred, and the number of instructors to nearly eight thousand.

Classes of
Inhabi-
tants.

The inhabitants are divided into nobles, citizens, and peasants. The first class, though differing in titles and rank, have all equal privileges; the principal distinction betwixt them is, that, in the Assembly of the States, or Diet, the Magnates have personally a seat and vote; and the other nobles vote by their representatives. The higher clergy are considered as nobles, and enjoy like privileges. The nobility can alone possess free lands, or those enjoying the *jus dominicæ*, and they are exempt from taxes, tithes, and the quartering of soldiers; but, on the other hand, they are bound to perform personal military service, when the pressure of circumstances compels the Diet to decree the levy en-masse, or, as it is called, the *insurrection*.

The citizens, or burghers, are the inhabitants of those cities which own no superior lord but the mo-

narch. These have privileges similar to the nobility, by which they are exempted from the payment of taxes and tithes, and from the quarterings of the military; and their deputies have seats in the Diet. They are governed by their own magistrates, and manage their own local funds. They cannot, however, hold estates out of their cities, nor institute a suit against the nobles, in their individual names, but only in that of the corporation to which they belong. The peasants generally are slaves, but with a more or less mitigated degree of servitude; and some few, under the denomination of German, or other colonists, are free. The lot of the common peasants has, however, been of late years much improved. They are more protected against the power of their lords, by being allowed to acquire property, by being permitted to leave their estates to their heirs, and to become, if they can do so, burghers of the royal cities. Their condition is, however, still a severe one, as they bear almost all the burdens of the state, and are incapable of commencing suits in the courts against either the nobility or burghers.

The northern and western sides of Hungary are remarkably mountainous. The Carpathian mountains form a semicircle, extending from the south-east portion of the kingdom till it meets the Danube on the western frontier. In the circle they describe, many projecting ranges extend themselves into the level land. On the western side, the Carinthian mountains cover a considerable portion of the kingdom. The highest points of the Carpathian mountains are the Lomnitzer Spitz, 8,545 feet above the level of the sea; the great Krywan, 8,218; the Caesmark, 8,194; and the Unack, 7,597. The loftiest of the Carinthian mass, though it can be scarcely said to be in Hungary, is the Terklou, which is elevated to 10,485 feet. To the eastward of this extend the Norischen and Rhetian Alps, the highest of whose summits, within the Austrian dominions, attains the height of 14,814 feet. The greatest extent of level land in Hungary is found to the eastward of the river Theisa, forming a rich plain of more than 20,000 square miles. Another level, called the Three Cornered Plain, is found to the eastward of the Danube, beginning near Presburg, whose base line extends 150 miles in length. The soil is as various as the elevation of the land; on the mountains it is dry and sterile; on the terraces that surround them, of moderate fertility, and of most luxurious richness on the plains, but mixed with considerable tracks nearly barren, where, for many miles, neither tree, stone, bush, or living creature are to be seen, with sand-hills, varying their position with the violent storms that frequently occur.

Hungary, however, is a country highly productive, yielding the largest proportion of the necessaries of life of any part of the ancient Austrian dominions, and furnishing, from its surplus, large quantities of corn, tobacco, fruit, wine, and cattle, to the neighbouring states. According to the account of Grellman, the extent of land is 39,329,000 jochs, which are nearly equal to an English acre. Of this land only 23,905,126 jochs are in cultivation; the remainder is composed of sandy deserts, lakes, morasses, and barren mountains. The productive lands

Hungary. are thus divided: 4,897,218 arable, 638,767 gardens, 911,176 vineyards, 2,129,225 meadows, 5,536,000 pastures, 850,000 ponds, and 8,940,740 woods. The northern part of Hungary scarcely produces sufficient corn for its own consumption; but the south is the granary, not only for the northern part of the kingdom, but, after deficient harvests, for a great portion both of Germany and Italy. The corn consists of wheat, rye, barley, oats, peas, and in the most southern parts, of rice and maize. Next to the cultivation of corn, the growth of wine is the most considerable object of attention, and managed with the most care. The wines of Tokay have long been celebrated through Europe, and are of the first class of sweet wines; but the wines of Edenburg, of Rust, and of Ofen, are very highly valued, though but little known beyond the boundaries of the Austrian empire. The whole of the annual produce of wine is estimated by Blumenbach at 4,500,000 hogsheads, and valued at near ten millions Sterling. Notwithstanding the proportion of wood land, the eastern part of the kingdom is much distressed from the want of fuel; but the west furnishes much wood, both for firing and building, and considerable quantities of gall-nuts, turpentine, pitch, tar, and pot and pearl ashes, for the supply of the surrounding countries. The other productions of agriculture, which furnish commerce, are hemp, flax, and tobacco. This last article has been long and successfully cultivated; and that produced in the provinces of Tolna, of Fünfkirchen, and in the peninsula of Murakoz, is highly prized for its peculiar aromatic flavour.

The breeding of cattle is an important branch of the rural economy of Hungary. The horses, though small, are active and hardy, but, in spite of the measures pursued by the government to improve the races, are still much inferior to those of most parts of the empire. They are generally set to work at too early a period, and their food is usually scanty and bad. They have, however, been somewhat improved of late years, by the institution of studs in different parts, whence stallions are gratuitously supplied. The whole number of horses does not exceed 180,000, of all kinds. The horned cattle are a race much valued in every part of the empire, though they receive but little attention. The extensive *Steppes* between Debretzen, Temeswar, Neusatz, and Pest, are the native homes of these beasts. Their number was 886,900 oxen, and 1,508,100 cows. These, by their sale to the surrounding countries, produce annually near L.500,000 Sterling. The numbers of the sheep are stated to be upwards of 8,000,000. There are prodigious flocks on the plains between the Danube and the Theisa, and on the elevated grounds of that district. The wool is coarse, and the owners estimate the cheese, milk, and flesh, more than the fleeces. In Western Hungary, on the other hand, the large flocks have been much improved of late years, by crosses with the Merino breeds, and with the sheep of Padua, yield fine wool, which, to the value of L.500,000, is exported. Swine are reared in abundance; and though, when cured, they form the principal animal food of the inhabitants, there are yearly from 200,000 to 250,000 of these animals exported. The feathered tribes

furnish a part of the annual wealth of the country. The greater part of the goose feathers, in which the Jews of Prague trade, come from Hungary; and the capital of the Austrian dominions is supplied from thence with that commodity. The rearing of silk-worms has been of late much attended to, in some of the southern parts of Hungary, especially in the Banat. The mulberry trees are very flourishing, and great progress is expected in future, but the undertaking is yet in its infancy.

The southern part of Hungary is a country enriched by minerals of various kinds. About two-thirds of the mines belong to the crown, and are worked on account of the government, under an expensive system of administration, and with a profusion of royal officers. These are formed into four divisions, the principal seats of which are at Chemnitz, Schmollnitz, Nagybanja, and Oravicza, and employ, in the various operations, about 45,000 workmen. The labourers, occupied in these mining operations, are generally emigrants from Moldavia and Wallachia. The whole produce of the mines, as well as the varying accounts of André and of Schwartzner can be reconciled, average, in a series of years, as follow:

Gold,	16,800 ounces.
Silver,	686,500 do.
Copper,	38,000 quintals.
Lead,	24,000 do.
Iron,	192,000 do.
Quicksilver,	130 do.
Antimony,	5,250 do.
Cobalt,	5,000 do.
Calamine,	500 do.
Alum,	1,800 do.
Natron,	15,000 do.
Salt,	47,000 tons.
Coals,	30,000 do.

The manufactures of Hungary are yet in an infant state. The kingdom has been long accustomed to supply raw materials to the surrounding countries, and to draw from them their manufactured goods. The inhabitants are not disposed to labour in confined houses; and, till within the last twenty years, their principal occupation, exclusive of agriculture, was confined to making very coarse cloths, and various kinds of wood ware, for furniture, musical instruments, and toys. The spinning of flax is a domestic manufactory carried on by the females of almost every peasant's family; the annual quantity produced is estimated at sixteen million of ells, or about ten million yards, the far greater part of which is consumed within the kingdom. The principal bleaching works are at Rosenau, where about 300,000 ells are annually whitened, all of the finer kind. There is much woollen cloth made in small manufactories scattered over the whole kingdom, which is of a coarse quality, and adapted for the use of the peasantry. Within the last thirty years more extensive factories have been established in Gacs, Illawa, Kaschau, Munkatsch, Lipersdorf, Mosztenie, and Presburg. These have been mostly founded by Germans, and the greater part of the operative people are of that nation. At these places the use of vari-

Hungary. — One machinery has been introduced, and the cloth made in them, from the wool of a mixed breed of sheep, partly of the Merino and partly of the Paduan races, is of fine quality and well finished. There are forty paper-mills in Hungary which produce printing and writing paper, all of a very wretched quality, except some from the mill belonging to the University, which is tolerably good. Silks and ribbons are made at Pest, Groswarden, and Presburg, but to a very small extent. The leather of Hungary is much valued through the whole Austrian territories, but the quantity of curried leather, prepared mostly at Presburg, is not equal to the consumption, and the hides of their cattle are sent to Germany, from whence they return in a state fit for use; the tanneries are numerous in Presburg, Funfkirchen, Ratko, Zips, and Debreczyn. The iron produced by the native mines is manufactured into the various articles which the wants of the inhabitants require, at Zips, Abouigvar, Sarosch, Zemplin, Vorschod, and through the whole county of Gomorer. The best steel is made in Diosgyver, and the vicinity of Neusol; and the swords and other weapons manufactured in the different hard-ware districts are esteemed to be of excellent quality, though of clumsy and grotesque forms. Glass is made (but scarcely any but green) in twenty-five glass-houses in different parts of the kingdom. The sugar refiners supply the domestic consumption. Smell and tobacco are made almost exclusively from the plants raised on their own soil. The soap of Hungary, which is very good, is principally made from tallow in Debreczyn, where there are seventy-eight manufactories of that article. Linseed-oil, oil of turpentine, corn spirits, cordials, especially Rosiglio, and a medicine for wounds, known through Germany by the name of the Hungarian Balsam, refined saltpetre, and pearl ashes, are the productions of the other manufactories.

Commerce. — Hungary is surrounded on every side by the other Austrian dominions. The states of that country are proud of their independence as a separate kingdom, and tenacious of their privileges, especially of their exemption from the taxes imposed by the Cabinet of Vienna. As the Emperor's government has no wish to embroil itself with the states by attempting internal taxation, it extracts a revenue by surrounding Hungary with customhouses, where tolls are collected on every commodity that enters into the kingdom, or passes from it into the hereditary states. The toll thus collected is one-thirtieth part of the commodity, or three and a third *per cent.* on the value of it. The very high rate of carriage arising from the bad state of the roads is, however, a greater impediment to the exchange of commodities than even this tax at the frontiers. The principal trade of Hungary, beyond the immediate boundaries, is with Poland and Silesia, which countries draw their wine from thence; and with the north of Italy, to which its surplus corn is transported. The port of Fiume is connected with Hungary by the only good roads the kingdom possesses, and may be considered as its haven for exportation and importation, and as alone bringing it into contact with distant countries. The central point of internal trade is Pest, where, at four

great fairs, the concourse of buyers and sellers is so great, that the prices settled by them, if they do not absolutely govern, in a great degree regulate those of the other parts of the kingdom. From the central city the commerce diverges in four great branches; 1st, Towards the German Austrian dominions by Raab, Presburg, Komorn, and Oedenburg, at each of which places considerable business is transacted, 2d, Toward Galicia, through Kaschau, Eperies, and Leutschau; 3d, To Sieberburgom, Moldavia, and Wallachia, through Lebreeczyn, Ezegeidin, and Temeswar; and, 4th, To the Turkish dominions beyond the Danube, through Neusatz and Semlin. At all these places considerable annual fairs or markets are held, which are resorted to by vast numbers of merchants, not only from Germany and Poland, but by the Turks, Armenians, Greeks, and even Tartars. Besides the marts at these cities, there are in Hungary sixteen hundred other places where annual fairs are held. The means of internal transit furnished by the rivers are a great assistance to commerce. The Danube is navigable for craft of two hundred tons burden, the Theisa for those of one hundred, and the other rivers, the Save, the Drave, the Wara, the Gran, the Unna, and the Kulpa, are all navigable in smaller vessels of various capabilities. Although the roads generally are miserably bad, yet some have been constructed for the purposes of trade, called *Kommerzialstrasse*, which, commencing at Pest in six different directions, cross the kingdom. Though not very good, or only so when compared with the other roads, they afford communications; but the want of bridges over the different rivers makes every removal of commodities both dilatory and troublesome. The paper money which Austria circulates through all her dominions, and which is greatly depreciated, when compared with the precious metals that are used as measures of value in all the other parts of Europe, makes any returns in the amount of exports and imports very indefinite, without going back to a period prior to any sensible depreciation. We have, therefore, extracted from various accounts the amount of the trade of Hungary for the year 1802. Since that time the apparent amount has been swelled in figures, but, as the paper has fallen in value, it has created an illusive increase without any correspondent one in intrinsic value. The fluctuations in the relative value of the paper money have been very great, so that, without knowing its precise relation to metallic money at the given periods, any accounts of the extent of the trade at those periods must be as uncertain as the then value of the currency.

Trade of Hungary in 1802.

	Exports in Gulden.	Imports in Gulden.
Cattle,	8,483,492	682,171
Corn and other fruits of the fields,	2,816,338	266,554
Other eatables,	412,253	290,802
Honey and wax,	203,865	3,275

Total in gulden about 10th of the pound sterling,	24,514,96	18,390,111

The balance of commodities between Hungary and the other parts of the Austrian dominions is thus, 6,124,878 gulden, or about L.600,000 in favour of the former.

The government of Hungary is a limited monarchy, hereditary in the house of Hapsburg at present; but, in case of the failure of all the branches of that family, the king, or rather dynasty, becomes elective by the assembled states or diet. The laws by which the constitution was founded, and by which it is maintained, are the *Golden Bull* of their king Andrea II., dated in 1222, the Magna Charta of the nobles, whose privileges are principally regarded; and these have been confirmed by the peace of Vienna in 1606, and of Lintz in 1647. By these two treaties also the free exercise of their religion is secured to the Protestant sectaries. All these interests were further confirmed by the diet of Presburg in 1687, and by the inauguration diploma of Leopold II. in 1790. These various charters and acts of the states have merely secured to the privileged orders their various ancient rights, but have left the peasantry, the great mass of the population, in the same state of subjection as before their promulgation.

The King

The whole executive power is vested in the monarch. He is the source of all titles and offices, nominates to the higher ecclesiastical dignities and to the benches of justice. He makes war and peace, can call together and dissolve the diet, and draw forth the whole military population. He receives the incomes of all vacant ecclesiastical benefices, and is heir to the property of such noble families as become extinct. The direction of the universities and colleges belongs to the King, but to the higher offices in

them he can only appoint those who are of noble birth. Hungary The appeals to Rome on the affairs of the Catholic church can only be made through him, and the royal authority has been constantly exercised to contract the number and limit the causes of such applications. The King must be of the Catholic religion, and, at his inauguration, must swear to maintain the privileges and rights of the states; notwithstanding this oath, by various circumstances, many arising out of the late long wars, the power and influence of the Crown have been recently very much extended. Within six months after succeeding to the throne, the King must call together the states, and in their presence, in the open air, swear to maintain the privileges of the states, to leave the crown of St Stephen within the kingdom, and to allow the states to elect a King, upon failure of issue both male and female of the Emperor Charles VI. Joseph I. and Leopold I. During a minority, the Palatine is guardian of the King and kingdom; but the monarch is capable of assuming the exercise of power when he has completed his fourteenth year.

The States of Hungary (*status et ordinis*) consist of, 1st, The Prelates, to which class belong the Archbishops, Bishops, Abbots, and Priors of the Greek and Catholic Churches; 2d, The temporal Barons and Magnates, the High Bailiffs of the provinces, and the Counts and independent noble proprietors of estates; 3d, The Nobility, or Knights, who do not attend personally, but choose two deputies for each county (*komitat*) or province; and, 4th, The Deputies from the royal cities. These members are said to be the representatives of Hungary, whilst the mass of the inhabitants, in their law described as *miseri plebs contributiva*, have no connection with public affairs, except by paying taxes and furnishing recruits; from both of which services the nobles and clergy are exempt. The purposes for which the States assemble are the coronation of the King,—the election of a Palatine,—the admission to or exclusion of nobles and cities from their rank,—the granting subsidies and imposing taxes, and the framing new laws, or rather giving the assent of the assembly to such laws as the King may enact. By the constitution, the States should be convened every five years, or whenever any pressing circumstances require their assembling. Of these circumstances the King must judge, as the States are only convened by his summons. They meet in two chambers, or, as they are denominated, tables. The Magnates' table is composed of the royal barons, the high hereditary officers of the kingdom, and the prelates, counts and free landlords. The other chamber, called the States' table, consists of the deputies of the *Komitats*, or the suppleans of the nobles, the representatives of the royal free cities, and the persons appointed by such Magnates as do not attend, who are called *Ablegati absentium*. Though the States meet but in two chambers, yet they vote in four distinct bodies, and the absolute majority of those present determine each question in that body. If the King and three of these bodies determine any point, it becomes a law; and the fourth body has no suspending power. The King appears personally, or by his commissioner, and claims his pre-

HUNGARY.

Hungary. rogatives, and the States demand a confirmation of their rights. At the Diet in 1792 were present 30 Bishops and other ecclesiastics, 178 Counts, 131 Hereditary Officers and Barons, 16 Law Officers, 30 Deputies of Chapters, 98 Representatives of *Komitats*, 115 Suppleans of absent Magnates, and 82 Deputies of Cities. The sitting of the Diet depends on the King, who has usually dismissed them as speedily as possible, out of regard to the general welfare of the people. During the meeting of the Diet, all the courts of justice are shut up, and the deputies of the free cities and of the *Komitats* are maintained at the time of the session at the expence of the people who send them, whilst the hereditary officers are kept by the Crown. From these regulations, it is not to be wondered at that no anxiety for the meeting of the Diet is manifested by any part of the kingdom. The King is well aware that no considerable sum beyond what is necessary for the expences of the local government, will be often granted by the Diet; and when it is granted, as the whole is squeezed from the hard earnings of the peasants, it is collected with difficulty, and produces great oppression. As each *Komitat* has its own provincial Diet, in which its affairs are discussed and regulated, and to which appeals from the courts of justice of the nobles (*Herren Stuhls*) can be made, there is less occasion for the assembling of the general Diet; and though, by the constitution, that body should meet every five years, yet, by a general acquiescence, its periodical convocation has been of late dispensed with. Whenever the Diet is convoked, the summons of the monarch states the purposes for which they are to meet, in the orders to these subordinate diets; and no other proposition is or can be produced at the assembly. The local diets thus have an opportunity of discussing the propositions that are to be made to the general assembly, of determining what part to take, and of instructing their deputies in what manner to vote. No project of a new law originates with any of the States; and the sittings, though they have been formerly very stormy, have been, of late, rather in compliance with ancient forms, and for purposes of display, than for any objects of great utility.

Great Officer. The principal officer of the kingdom is the Palatine, who is the representative of the King, president of the Diet, and of the Supreme Court of Justice, dispenser of pardons, and mediator between the Monarch and the States; his office continues but one year, but he may be re-appointed. Next to him is the Judge of the Supreme Court, who is the president of the other two, and fills the office of Palatine in the absence of that chief. The Ban of the Croats follows next in rank, but has no official duties unless at the coronation, when he carries the golden ball. The hereditary treasurer (*Tavernicus*) has a seat in the supreme council, and is Captain of the noble Hungarian Body Guards, w. perform the palace duty.

Chancery Court. The administration is conducted by the Emperor through the means of the Hungarian Court of Chancery in Vienna, which is constituted of twenty-four state-councillors, viz. three ecclesiastics, eleven mag-

nates, and ten of knightly rank, all nominated by Hungary. the monarch. This college exercises the superintendence over churches, schools, and charitable establishments, administers the funds of the universities and convents, and regulates the agriculture, the trade, and the feudal claims. This body has no original jurisdiction in matters of finance or of justice, but may be appealed to by the provincial diets, or the local courts of law.

The primary courts of law are under the control of the nobles, who appoint the judges and direct the procedure. The oppression in such courts towards those not noble has been long excessive, and, though somewhat mitigated since the reign of Maria Theresa, bears still the deep impression of the worst periods of the feudal government. The whole system of laws seems calculated only to secure and perpetuate to the nobles the enormous power they possess. The nobles are exempt from all taxes and imposts of every kind; the only duty they owe to the state is that of personal service in war. If a person not noble assaults one who is so, the legal punishment is death, which is, however, now usually commuted into the forfeiture of all his property, with the privilege of reclaiming it whenever he shall have the means of paying for it a stipulated portion of the value. If a peasant is injured by a noble, to whose estate he is attached, he can have no redress, since he can only sue for it in the name and through the medium of the very person against whom he seeks it. The court in which his complaint is to be heard, not only consists of persons who are generally the dependants of the presumed offender, but moreover they can only be assembled at his summons. If a peasant is injured by any other noble, he cannot seek redress in his own person, but only through the intervention of him on whose estate he lives; and such is the contempt in which the peasantry are held, that even this privilege must very often be nugatory. The law of entail is another injurious privilege of the nobility, common, indeed, to all the feudal countries, which puts it out of their power to alienate the estates to the detriment of the successors. The effect of this is, that the possessions of the nobles are of enormous extent, embracing, often, whole *Komitats*; and they are held upon tenures which convert them into the nature of principalities. The kingdom, indeed, partakes more of the nature of a great military confederation of subordinate chiefs, under one hereditary leader, than of any other known form of government. As all the descendants of noble families are themselves noble, whilst property remains almost unalienable, the poverty into which individuals belonging to distant branches of these families fall is in proportion to their number. In Hungary, it is estimated that one person in twenty is of noble birth, all possessing the obnoxious privileges here noticed; many of them, though free from all taxes, sunk to a state of most abject poverty, and some of them filling the offices of peasants or servants. The inhabitants of the free cities are supposed to be about equal in numbers to the nobility, and the remainder of the people, according to these estimates, amounting to eighteen

HUNGARY.

Hungary. out of every twenty, can have no protection from the laws, nor any resource when injured or oppressed by their superiors. "The noble," says Dr Bright, "pays no tribute, and goes freely through the country, subject to neither tolls nor duties; but the peasant is subject to pay tribute, and although there may be some nominal restrictions to the services due from him to the government, it can safely be said, that there is no limit, in point of fact, to the services which he is compelled to perform. Whatever public work is to be executed,—not only when a road is to be prepared, but when new roads are to be made, or bridges built, the county meeting gives the order, and the peasant dares not refuse to execute it. All soldiers passing through the country are quartered exclusively upon the peasantry. They must provide them, without recompence, with bread, and furnish their horses with corn, and whenever called upon, by an order termed a *forespan order*, they must provide the person bringing it with horses and means of conveyance. Such an order is always employed by the officers of government; and whoever can in any way plead public business as the cause of his journey, takes care to provide himself with it. In all levies of soldiers, the whole falls upon the peasant, and the choice is left to the arbitrary discretion of the lord and his servants."

From the same intelligent traveller we learn, what, indeed, the observations of all ages has taught, that whilst the nobles are hospitable, high-spirited, well informed, and zealous to promote such institutions and projects as they think calculated to benefit their country, the peasantry are not only poor but idle, dissolute, and dishonest. Perhaps in no other country of Europe is highway robbery so frequent; and, as a remarkable trait in the character both of the noble and the peasant, we are told, that to every nobleman's house a prison is attached, in which are to be constantly found from ten to twenty miserable wretches, pinioned in a way which would not be tolerated in England towards the worst felons. The dungeons in which they are immured are far more dismal and wretched than any prison in London can exhibit. The extreme viciousness of the Hungarian peasantry seems to have extinguished all feeling in the breasts of the higher nobles for their degraded state; and instead of the wise policy, which, by meliorating their condition, would improve their morals, they are left to endure those punishments which a different state of society would be likely to render unnecessary.

finances. In speaking of the finances of the Hungarian government, a difficulty arises from the state of the currency. In the whole of the Austrian dominions, the currency is paper money issued by the monarch, which has gradually depreciated, and, by affecting the prices of all commodities, has rendered them variable, and extended those variations to the public revenue; hence the accounts of the national income, given by different writers, are excessively discordant. According to the best view we can take, the revenue, if reduced into metallic money, would amount to nearly L.2,000,000 Sterling, the greater part of which is expended by the local diets of the several *Komitats*, and a very small portion is remitted to

Vienna. This revenue is derived from the following sources: 1. The royal domains; 2. The regalia, among which the most considerable are the salt mines and salt springs, and in which is included the coinage, the mines, the toleration tax on the Jews, the profits on posting, and the revenues of the vacant ecclesiastical benefices; 3. The land-tax levied on the peasants, which amounts to nearly L.400,000 Sterling; and, 4. The profits arising from loans of money by the royal banks.

The military force raised by Hungary consists of twelve regiments of infantry of 3857 men each, and ten complete Hussar regiments of 1698 men each, making together 63,364 regulars, which are recruited from among the peasantry, and are much increased in time of war, when danger threatens the country, and what is termed the insurrection is called forth. In 1797, this irregular force was 18,000 cavalry and 35,000 infantry; in 1800, it was 11,000 horse and 26,000 foot; and, in 1809, 18,000 horse and 21,000 foot. From being tenacious of their privileges, and from the organization and the ranking of the different portions of this noble force, being partly under the control of the monarch, and partly under that of the diets, it has never been found very efficient when engaged in field operations.

The southern frontier on the boundary of the Turkish empire is planted with a military colony, who hold the lands they cultivate upon the terms of being always ready for active service when a war breaks out with that power. Though scattered on different small farms, they are all regimented, and have been drilled, so that they are capable of affording some defence against such undisciplined bodies as the Turks usually employ in their predatory irruptions.

Though Hungary has a national language, yet it is not generally spoken, nor supposed to be understood by more than one-third of the inhabitants. The only written language, until within a very late period, was the Latin, in which all their laws and public proceedings were promulgated; and it is still the most common medium of communication. It was not till the reign of Maria Theresa that any experiments were made to improve and polish the national language. When she formed her Hungarian guards, a number of young men of noble families were drawn to Vienna, where they had means of knowing the estimation in which the cultivation of learning was held in the more civilized parts of Europe, and were taught to feel the inferiority of their native country, in not possessing a national language and national literature. This stimulated them to exertions to remove the stigma, and give birth to most of those writings of which the Hungarians boast. The cultivation of the vernacular tongue was further promoted by the attempt of the Emperor Joseph to introduce the German tongue into their public transactions; this roused the patriotic spirit of the Hungarians, and the effect of that spirit became visible in the extension and improvement of the native language. Since that period the study of this language has produced some good poets, who have generally dedicated their powers to the praises of their country, and to recording the merits of its most distin-

Hungary guished natives. As the subjects of their poetry are very little known beyond the limits of the country, we must trust to the reports of those who feel the most interest in the subjects of which it principally treats, and who, for that reason, may not be the most unbiassed critics.

The inhabitants of Hungary, for the greater part, live in villages, and those residing in the cities and towns are not supposed to be more than a twentieth of the whole number. The principal cities, and their population in 1817, were,

Extent and Boundaries. HUNTINGDONSHIRE, an inland county of England, and, except Rutlandshire, the smallest of the whole. It is bounded on the north-east and east by Cambridgeshire, on the north-west and west by Northamptonshire, and on the south by Bedfordshire. Its greatest breadth is twenty-three miles, and its greatest length thirty miles, and its square contents are 350 miles.

Towns and Population. It is divided into four hundreds, containing six market towns, and 104 parishes, in which are 7719 houses. At the census of 1811 the number of inhabitants was 42,208, viz. 20,402 males, and 21,806 females. The baptisms of the preceding year were 613 males and 591 females, the burials 445 males and 404 females, the marriages were 357. The number of families were 8808, of whom 5361 were employed in agriculture; 2205 in trade and manufactures; and 1242 in various occupations. The towns containing more than 1000 inhabitants are as follow:

Four members are returned to Parliament, viz. two for the county, and two for the borough of Huntingdon.

The appearance of the county is of three descriptions. In the south-east it is an extensive plain of rich meadow land, the middle varying in its surface with gentle undulations, and without many inclosures or many woods; the higher part was anciently a forest, and still contains a great extent of woodland, whose foliage gives beauty to the scenery. On the north-eastern side a portion of the county is fine land, comprizing a part of what is commonly called Bedford level, comprehending nearly one-fifth of the whole county.

The two most considerable rivers are the Ouse and the Nen. The Ouse enters from Bedfordshire, and crossing the whole of the county, passes into Cambridgeshire in its way to the German Ocean. It is navigable in its whole extent through Huntingdonshire, and forms an important means of intercourse. The Nen enters from Northamptonshire, and runs to the marshes; it is also navigable the greater part of its course. Besides these, the Cam passes through a part of the county. There are three lakes, viz. Whittlesea mere, Ramsay mere, and Ugg mere; the first of these is the largest, and covers an area of several miles in extent. It affords excellent fishing, and pleasant sailing, which induces many parties of pleasure to visit it in the summer season. Projects for draining this lake have been formed, as the water is not deep, and the soil excellent; but they have not yet been carried into execution.

The county of Huntingdon scarcely contains any manufactures, excepting some spinning, performed by the females; but the improvements of machinery in other districts have much diminished that mode of employment. The only trade is that of corn, cattle, and the wool of the few flocks of sheep.

Agriculture is the principal pursuit of the district. The marshes and meadows are highly productive, and many oxen are fattened on them, without any other food than their natural grass. Much of this land is under the plough, and produces most abundant crops of oats and coleseed; the mills for making the latter into oil are numerous. The hay from those fens is very considerable, but on the banks of the rivers they are subject to great floods, which sometimes destroy the harvest of the year. Though these lands are very valuable, yet the expence of draining them causes a great deduction from their value.

The soils in the upland parts of the county are various, but consist principally of a tenacious clayey loam, or of a deep gravelly loam with some clay. Much of this is in open common fields, where each occupier is compelled to follow a rotation like that of his neighbours. On the best of these lands the usual course of cropping is a year's fallow, then wheat or barley, next beans, and then barley or wheat. On

Hunting-
donshire.

Hydraulics.

the land of a quality somewhat inferior, a three course rotation of fallow, wheat, and peas or beans, is pursued. In those fields that are calculated for turnips, that root is succeeded by barley and wheat, or by wheat and barley. The average produce of the lands is stated at five quarters of barley, four of oats, and three and a half of wheat to the acre. The excellent practice of sowing clover between two corn crops is followed to a very small extent. The farms are generally small, few rentals exceed L.200 *per annum*.

The sheep of Huntingdonshire are a mixed race, composed of crosses of the Lincolnshire and Leicestershire breeds, with the native kinds. They are without horns, of very imperfect shape, but are found profitable from the quantity of wool they produce; their fleeces usually weighing from seven to eight pounds each. The sheep of the original race of the county are much inferior to those produced by the crossing with the better kinds; many of these are still found in the open commons, and their fleeces seldom exceed four pounds in weight. The cows are bred with little attention, and are a compound of many races. Very little butter or cheese is made; the principal object being the suckling of calves to supply veal for the London markets. Many horses are bred in the lower part of the county, but without much attention to their races. From this practice of breeding, it has become very general to execute all the agricultural work with mares.

The remains of antiquity in this county are principally of Roman origin; among them are the vestiges of the three roads, which were constructed by that people across the country. The remains of Ramsey Abbey and Castle, the seat of the family from which Oliver Cromwell, a native of this county, sprung, are of venerable date. The monks who formerly occupied it were highly celebrated for their knowledge of the Hebrew language. The churches of Bluntisham, St Ives, and St Neots, and the Castle of Kimbolton, exhibit marks of high antiquity.

The most remarkable noblemen and gentlemen's seats are, Kimbolton, Duke of Manchester; Buccleugh Palace, Bishop of Lincoln; Connington Castle, J. Heathcote, Esq.; Elton, Earl of Carysfort; Hinchinbroke, Earl of Sandwich; Overton Longueville, Earl of Aboyne; Gains Hall, Sir James Duberly, Bart.; Place, P. Stanley, Esq.; Ramsey, William J. Fellowes, Esq.; Stirtloe, Launcelot Brown, Esq.; Stoughton, Earl Ludlow; and Upwood, Sir Richard Bickerton.

See Brayley's *Beauties of England and Wales*.—Stone's *General View of Huntingdonshire*.—And *Population Returns*. (w. w.)

HYDRAULICS. In addition to the general principles of Hydraulics, as they have been detailed in the article **HYDRODYNAMICS**, of the *Encyclopædia*, it will be necessary to give some account of the later attempts that have been made to improve the theory of this department of science, especially those of Mr De Prony, contained in his *Recherches Physico-mathématiques sur la Théorie des eaux courantes*, 4to. Paris, 1804; and those of Dr Thomas Young, in his

Hydraulic Investigations, published in the *Philosophical Transactions* for 1808.

Ingenious and important as the Chevalier Dûbuat's theory of the friction of fluids is admitted to have been, it cannot be denied, that it is extremely deficient both in the distinct elucidation of the physical grounds of the phenomena, and with respect to the neatness and simplicity of the methods of calculation. Mr Girard, according to Mr De Prony, was the first who entertained the fortunate idea of applying the theory of Mr Coulomb to the resistance of water flowing in pipes and canals; and in his two memoirs on the *Theory of Running Waters*, he proposes a formula depending on the sum of the velocity and its square, for the expression of the friction; and deducting a constant coefficient from twelve experiments of Chezy and Dûbuat, he obtains a formula equally correct with that of Dûbuat, and far more simple.

Mr De Prony has obtained an expression founded on the same theoretical principles that Mr Girard had adopted, but much more perfect and accurate, and agreeing very sufficiently with all those of Mr Dûbuat's experiments to which he has applied it. But Mr De Prony's formula, as well as Mr Dûbuat's, fails altogether, when we attempt to employ it for the computation of the discharge through very slender tubes, and though his work was printed a year or two earlier than Dr Young's investigations, it would have been impossible for this philosopher to make any use of it in his physiological inquiries, even if it had not been wholly unknown to him, since the resistances which he had occasion to compute were principally such as occurred in tubes considerably less than a thousandth of an inch in diameter.

The most material deviation of the experiments from the theory of Mr Coulomb and Mr De Prony appears to arise from the great comparative increase of that portion of the resistance which varies simply as the velocity, when the tubes become extremely small; and it is upon this circumstance that Dr Young has founded the principal characteristic of his theory of the circulation of the blood; the resistance, notwithstanding the extreme slowness of the motion of the blood through the capillary vessels, being almost entirely confined to those vessels; and in order to comprehend in one formula the whole of Dûbuat's experiments, together with those of Gerstner, and his own, on very small pipes, he has found it necessary to introduce, into the determination of the coefficients for expressing the two kinds of resistance, a quantity depending on the diameter of the tube, and capable of being readily computed from it, although by a formula which is founded on empirical evidence only. The method of calculation, however, appears to be equally general and convenient, and it will, therefore, not be superfluous to copy the particulars of the investigation in the words of the author.

Dr Young "found," he observes, "that the friction could not be represented by any single power of the velocity, although it frequently approached, for the same pipe, "to the proportion of that power, of which the exponent is 1.8; but that it appeared to consist of two parts, the one varying simply as the

Hydraulics. velocity, the other as its square. The proportion of these parts to each other must, however, be considered as different, in pipes of different diameters, the first part being less perceptible in very large pipes, or in rivers, but becoming greater than the second in very minute tubes, while the second also becomes greater, for each given portion of the internal surface of the pipe, as the diameter is diminished.

"If we express, in the first place, all the measures in French inches, calling the height employed in overcoming the friction f , the velocity in a second v , the diameter of the pipe d , and its length l , we may

make $f = a \frac{l}{d} v^2 + 2c \frac{l}{d} v$; for, it is obvious, that the

friction must be directly as the length of the pipe; and since the pressure is proportional to the area of the section, and the surface producing the friction to its circumference or diameter, the relative magnitude of the friction, "or the friction for any given portion of the section," must also be inversely as the diameter, or nearly so, as Dubuat has justly observed.

We shall then find that a must be .0000001 $\left(430 + \frac{75}{d} - \frac{1440}{d+12} - \frac{180}{d+\frac{1}{2}}\right)$, and $c = .0000001 \left(\frac{900dd}{dd+1000} + \sqrt{\frac{1}{d}} \cdot \left[1050 + \frac{12}{d} + \frac{9}{dd}\right]\right)$. Hence it is easy to calculate the velocity for any given pipe or river, and with any given head of water. For the height required for producing the velocity, independently of friction, is,

according to Dubuat, $\frac{vv}{478}$, or rather, as it appears from

almost all the experiments which I have compared, $\frac{vv}{550}$; and the whole height h is therefore equal to f

+ $\frac{vv}{550}$, or $h = \left(\frac{al}{d} + \frac{1}{550}\right)v^2 + \frac{2cl}{d}v$; and making $b =$

$\frac{1}{al \cdot d + .00182}$, and $e = \frac{bcl}{d}$, $v^2 + 2ev = bh$, whence $v =$

$\sqrt{(bh + e^2) - e}$. In order to adapt this formula to the case of rivers, we must make l infinite; then b becomes

$\frac{d}{al}$, and $bh = \frac{d}{a} \cdot \frac{h}{l} = \frac{ds}{a}$, s being the sine of the inclination, and d four times the hydraulic mean depth;

and since e is here $= \frac{c}{a}$, $v = \frac{\sqrt{(ads + cc) - c}}{a}$; and in

most rivers, v becomes nearly $\sqrt{(20000ds)}$.

"In order to show the agreement of these formulæ with the result of observation, I have extracted," says Dr Young, "as indiscriminately and impartially as possible, forty of the experiments made and collected by Dubuat; I have added to these some of Gerstner's, with a few of my own; and I have compared the results of these experiments with Dubuat's calculations, and with my own formulæ, in separate columns." "It appears from this comparison, that in the forty ex-

periments, extracted from the collection, which serve as a basis for Dubuat's calculations, the mean error

of his formula is $\frac{1}{24}$ of the whole velocity, and

that of mine $\frac{1}{25}$ only; but if we omit the four experiments,

in which the superficial velocity only of a river was observed, and in which I have calculated the mean velocity by Dubuat's rules, the mean error

of the remaining 36 is $\frac{1}{37}$, according to my mode of

calculation, and $\frac{1}{37}$, according to Mr Dubuat's; so

that "the accuracy of the two formulæ may be considered as precisely equal with respect to these" forty experiments. In "six experiments which Dubuat has wholly rejected," "without any very sufficient reason," "the mean error of his formula is about $\frac{1}{24}$, and that of mine $\frac{1}{45}$. In fifteen of Gerstner's ex-

periments, the mean error of Dubuat's rule is $\frac{1}{9}$, that

of mine $\frac{1}{4}$; and, in the three experiments which I

made with very fine tubes, the error of my own rules

is $\frac{1}{15}$ of the whole, while in such cases Dubuat's formulæ completely fail."

"It would be useless to seek for a much greater degree of accuracy, unless it were probable that the errors of the experiments themselves were less than those of the calculations; but if a sufficient number of extremely accurate and frequently repeated experiments could be obtained, it would be very possible to adopt my formulæ still more correctly to their results.

"If any person should be desirous of making use of Dubuat's formula, it would still be a great convenience to begin by determining v according to this

method; then, taking $b = \frac{l}{h - vv : 478}$, or rather, as

Bangsdorf makes it, $b = \frac{l}{h - vv : 482}$, to proceed in

calculating v again "by the formula $v = 148.5$

$(\sqrt{d} - .2) \cdot \left(\frac{1}{\sqrt{b - HL\sqrt{(b+1.6)}} - .001}\right)$, since this determination of b will, in general, be far more accurate than the simple expression $b = \frac{l+45d}{h}$, and the

continued repetition of the calculation, with approximate values of v , may thus be avoided. Sometimes, indeed, the values of v , found by this repetition, will constitute a diverging instead of a converging series; and in such cases, we can only employ a conjectural value of v , intermediate between the two preceding ones."

Hydraulics. "Having sufficiently examined the accuracy of my formula, I shall now reduce it into English inches, and shall add a table of the coefficients, for assisting the calculation. In this case, a becomes .0000001

$$\left(413 + \frac{75}{d} - \frac{1440}{d+12.8} - \frac{180}{d+.355}\right), c = .0000001$$

$$\left(\frac{900dd}{dd+1136} + \frac{1}{\sqrt{d}}\left(1085 + \frac{13.21}{d} + \frac{1.0563}{dd}\right)\right), \text{ and}$$

Hydraulics. $b = \frac{1}{al \cdot d + .00171}$, e being $\frac{bcl}{d}$, and $v = \sqrt{(bh+e^2)} - c$,

or, for a river, " $= \sqrt{\left(\frac{ds}{a} + \frac{cc}{aa}\right) - \frac{c}{a}}$, as before;

and in either case the superficial velocity of a river may be found, very nearly, by adding to mean velocity v its square root, and the velocity at the bottom by subtracting it.

Table of Coefficients, for English Inches.

"Coulomb's experiments on the friction of fluids, made by means of the torsion of wires, give about .00011 for the value of c , which agrees as nearly with this table, as any constant number could be expected to do. I have, however, reason to think, from some experiments communicated to me by Mr Robertson Buchanan, that the value of a , for pipes about half an inch in diameter, is somewhat too small; my mode of calculation, as well as Dubuat's, giving too great a velocity in such cases."

It must, indeed, be confessed that, notwithstanding the convenience of this theory for calculation, with the assistance of the tables of coefficients, their determination from the diameters of the pipes is somewhat too complicated either for elegance or for probability, if considered as representing the law of nature. The formula of Prony, though it fails for small pipes, and would, therefore, have been useless for Dr Young's purpose, has the advantage of great simplicity, and even of superior accuracy, within certain limits of the magnitude of the pipes, although it seems to be indebted for this accuracy to accidental causes only.

If we take Dr Young's equation $v = \frac{\sqrt{(ads+cc)}-c}{a}$,

or $v = \sqrt{\left(\frac{ds}{a} + \frac{cc}{aa}\right) - \frac{c}{a}}$, and assume for a the constant mean value .0000377, and for c .00003466, we shall have $v = \sqrt{(26520ds+.845)} - .919$, which is equivalent to Prony's formula reduced to French inches.

For pipes Mr De Prony merely substitutes $\frac{h}{l}$ for s , ne-

glecting entirely the height $\frac{vv}{550}$ due to the velocity.

He also gives a still simpler approximation for common purposes, $v = \sqrt{\left(26513 \frac{dh}{l}\right)}$, or $\sqrt{(26513 ds)}$,

which differs very little from Dr Young's rule published in his *Lectures*, that "the velocity is a mean proportional between the hydraulic mean depth and the fall in 2800 yards;" for this, in French measures, would be $\sqrt{(27000 ds)}$. It is obvious, however, that in many cases these formulas must require considerable modification, since, when the velocity is great, the height due to it may become considerable, and since the friction in small pipes is certainly increased beyond its mean value: nor can these opposite causes of error be expected always to compensate each other even in pipes of moderate dimensions.

If we had a greater number of very accurate experiments, we might construct a sufficiently complete table of the values of a and c from their results alone, without any general formulas. Thus, taking $f = h - \frac{vv}{550}$, we readily obtain the equation, $a = \left(\frac{f}{v} \cdot \frac{d}{l} - \frac{f'v'}{v'l}\right)$.

$\frac{1}{v-v'}$, in which f and f' , v and v' , are the correspond-

ing values of f and v for the same pipe with different pressures, or for two pipes so nearly alike in diameter, that the coefficients may be considered as the

same for both; and then $2c = \frac{f}{v} \cdot \frac{d}{l} - av$: or for a

river, $a = \frac{ds}{v} - \frac{d's'}{v'}$, and $2c = \frac{ds}{v} - av$. But the results

of twelve double experiments, compared in this manner, afford a very irregular series only; thus:

HYDRAULICS.

No.	d	$10^7 a$	$10^7 c$	
1	262.5	681	Negat.	Exp.
2	258.5	387	1453	Dub.
3	5	344	478	
4	2.01	256	1156	
5	1	320	599	
6	1	296	1000	
7	1	214	2420	
8	.242	314	2020	
9	.167	351	2420	
10	.125	568	2870	
11	.2	156	4420	Gerstn.
12	.133	58	4690	
		12)3905	23526	
		325	1960	

It is, therefore, hopeless to attempt to deduce a good formula for the coefficients from these results alone, and we must be satisfied for the present either with Dubuat's formula, or Prony's, or with Dr Young's table. For a single instance of the comparative accuracy of these modes of computation, we may take an example from Mr Jardine's observation of the pipe supplying Edinburgh with water, as published by Dr Brewster. Here d was 4.5, h 612, l 179160, and v 20.52 English inches. We have, therefore,

$$a = .0000309, c = .0000532, \frac{l}{d} = 39813, a:d = 1.22023,$$

$$\frac{1}{b} = 1.222, c = 1.733, \text{ and } v = \sqrt{(500.8 + 3)} = 1.73 =$$

20.71, exceeding the observation by .19. Dubuat's formula falls short by .13 only, Prony's table by .96. It must, however, be observed, that in so great an extent of pipe, it is scarcely possible that some partial obstruction should not always occur, which must make the actual velocity somewhat less than the theory ought to give, so that the slight difference between the formulae of Dubuat and Dr Young can scarcely be said to be in favour of the former.

It is, however, remarkable that in this instance, as well as in some others, a single formula, which Dr Young had published in an abstract of Professor Eytelwein's book, is still more accurate than the more refined calculations. This formula is $v =$

$$50 \sqrt{\left(\frac{dh}{l+50d} \right)}, \text{ the measures being expressed in}$$

English feet; thus, in the example here computed, this formula gives us $v = 20.56$ inches. It is

$$\text{equivalent, for inches, to } v = \sqrt{\left(\frac{30000 dh}{l+50d} \right)} =$$

$$\sqrt{\left(\frac{30000h}{l+d+50} \right)} = \sqrt{\left(\frac{h}{.0000333l + .001} \right)}, \text{ which}$$

implies that c may be neglected in such pipes at least, and a may be taken $.17 \times 333$, which does not greatly differ from the tabular value for the given diameter. It has happened, from a combination of accidental circumstances, that Dubuat has been deprived of a considerable portion of his just merits,

in favour of Mr Eytelwein, without any kind of voluntary plagiarism on the part of this very respectable Professor. The author of the English abstract of his work was acquainted with Dubuat's book, only from having read the extracts, copied from it by Professor Robison, in his contributions to the *Encyclopædia Britannica*, and he was hence led into the mistake of supposing Professor Eytelwein the author of many improvements, which he had no more idea of claiming than he could have had of several modifications introduced into the "*Summary of Hydraulics*," chiefly extracted from his book, which appeared in the *Journal of the Royal Institution*, and which have been quoted as Eytelwein's.

The resistance occasioned by the flexure of a pipe, must not be neglected when any great accuracy is required in the determination of the water conveyed by it. Dr Young has pointed out the inadequacy of Dubuat's method of calculating this resistance, and his remarks may again be copied in his own words.

"Mr Dubuat," he continues, "has made some experiments on the effect of the flexure of a pipe in retarding the motion of the water flowing through it; but they do not appear to be by any means sufficient to authorise the conclusions which he has drawn from them. He directs the squares of the sines of the angles of flexure to be collected into one sum, which, being multiplied by a certain constant coefficient, and by the square of the velocity, is to show the height required for overcoming the resistance. It is, however, easy to see that such a rule must be fundamentally erroneous, and its coincidence with some experiments merely accidental, since the results afforded by it must vary according to the method of stating the problem, which is entirely arbitrary. Thus it depended only on Mr. Dubuat to consider the arc of a pipe bent to an angle of 144° as consisting of a single flexure, as composed of two flexures of 72° each, or of a much greater number of smaller flexures, although the result of the experiment would only agree with the arbitrary division into two parts, which he has adopted. This difficulty is attached to every mode of computing the effect, either from the squares of the sines, or from the sines themselves; and the only way of avoiding it is to attend merely to the angle of flexure as expressed in degrees. It is natural to suppose that the effect of the curvature must increase, as the curvature itself increases, and that the retardation must be inversely proportional to the radius of curvature, or very nearly so; and this supposition is sufficiently confirmed by the experiments, which Mr Dubuat has employed in support of a theory so different. It might be expected that an equal curvature would create a greater resistance in a larger pipe than in a smaller, since the inequality in the motions of the different parts of the fluid is greater; but this circumstance does not seem to have influenced the results of the experiments made with pipes of an inch and of two inches diameter: there must also be some deviation from the general law, in cases of very small pipes having a great "radius of" curvature; but this deviation cannot be determined without further experiments. Of the twenty-five which Dubuat has made, he has rejected ten

Hydraulics as irregular, because they do not agree with his theory; indeed, four of them, which were made with a much shorter pipe than the rest, differ so manifestly from them that they cannot be reconciled; but five others agree sufficiently, as well as all the rest, with the theory which I have here proposed, supposing the resistance to be as the angular flexure, and to increase, besides, almost in the same proportion as the radius of curvature diminishes, but more nearly as that power of the radius of which the index is $\frac{7}{8}$. Thus if p be the number of degrees sub-

tended at the centre of flexure, and q the radius of curvature of the axis of the pipe in French inches,

we shall have $r = \frac{p^2}{200000q}$ nearly, or more accurately

$r = \frac{.0000045 p^2 q^{\frac{1}{8}}}{q}$. These calculations are compared with the whole of Dubuat's experiments in the following table. The mean error of his formula in fifteen experiments, and of mine in twenty, is $\frac{1}{25}$ of the whole."

The methods of computation here proposed may be illustrated by a practical example, which is of a nature very likely to be of frequent occurrence. Let the length of a pipe l be 1000 feet, let it have five flexures, each equal in extent to a right angle with a radius of curvature q of six inches; let the height of the head of water h be ten feet, and let the quantity of water to be delivered be one ale hogshead, or fifty-four gallons in a minute; required the diameter of the pipe d .

Neglecting the slight difference between French and English inches, with respect to the effect of

curvature, we have $p = 450$, $q^{\frac{1}{8}-1} = .2085$, and $r = .0004222v^2$, which must be added to $\frac{al}{d}$, the co-

efficient of v^2 in the general formula. Now, since an ale gallon fills 10 yards of inch pipe, the velocity discharging a gallon in a minute by such a pipe would

be 6 inches, and for 54 gallons, 324 inches; consequently, for any other pipe, of the diameter and the velocity discharging a hogshead in a minute must be

$\frac{34}{dd}$. Hence we might obtain, by means of the for-

mula expressing the coefficients, a regular equation in terms of d and its powers, but it would be of too high an order to be at all manageable; the very general method, termed by arithmeticians the rule of double position, affords much the readiest solution. Thus, supposing $d = 4$, we have $a = .0000306$ and

$c = .0000556$, and since $\frac{l}{d} = 3000$, the coefficient al/d

becomes .0918, to which if we add .00171, according to the formula, and $r = .0004222$, we have $b =$

$\frac{1}{.0939322}$, and $e = \frac{bcl}{d} = \frac{.1668}{.0939322} = 1.776$, whence

$=(bh+e^2)-e = 8.70$; but $\frac{324}{16} = 20.25$; therefore,

the pipe is too small, and we must try five inches, a being .0000312, and $c = .0000507$; hence $al/d =$

.07488, and $b = \frac{1}{.0770122}$, $e = \frac{.1468}{.0770122} = 1.901$

and $v = 9.65$, while $\frac{324}{25} = 12.96$. Here the differ-

ences of the values of v are $+11.55$ and $+3.31$, their difference 8.24 answering to a difference of an inch in the diameters. We must, therefore, add $\frac{3.31}{8.24} = .402$, and the diameter required will be 5.40

inches; and if we wish for very great accuracy, we may repeat the calculations once more with this value of d .

The remainder of the investigations contained in Dr Young's two papers are more immediately connected with Physiology than with Hydraulics; and the interesting experiments of Girard, published in the *Memoirs of the Academy of Sciences* for 1818, relate almost entirely to the effects of temperature on the mechanical properties of bodies possessed of different chemical characters.

(R. T.)

I

JAINS.

JAINS (called by some JOINUS), a sect or rather race of Hindoos, found in considerable numbers in different parts of India, particularly in the southern peninsula. They form a class of dissenters from the established faith of Brahminism, so generally considered throughout India as alone founded on an orthodox basis. They deny altogether the authority of the Vedas, regarded by the genuine Hindoo as the holiest of books. They either disown, or sink into a subordinate station, all the grand objects of Hindoo veneration. In their hypothesis concerning the origin of the world, they have adopted opinions which seem to partake of the character of atheism. They do not, like the followers of the Vedas, acknowledge any spiritual and eternal Being, from whom the universe derived its origin. The material world, as well as the minds of all men and animals, are held by them to be eternal. They refuse to acknowledge any thing which is not, or has not been, the object of the senses. Upon this principle they deny the existence of any beings superior to man, and admit no objects of worship except men who have raised themselves by their merits to the rank of divinities. As, however, they set no bounds to the perfection which the human soul may arrive at, their most eminent saints and pontiffs (among whom they particularly celebrate Gomat Iswara Swami) partake almost the attributes of Supreme Divinity. To this station, however, they are exalted, not in consequence of a virtuous life, or of benefits rendered to mankind, but of those excesses of absurd and extravagant penance to which, throughout all India, such sovereign merit is attached. They have three ranks of ascetics, whom they call *Yatis*. The first, called *Anuvrata*, can be attained only by him who forsakes his family, entirely cuts off his hair, holds always in his hand a bundle of peacock's feathers and an earthen pot, and wears only clothes of a tawny colour. The second rank, *Mahavrata*, requires that all dress should be abandoned, except a mere rag to cover nakedness, and that the hair, instead of being shaven off, should be pulled out by the roots. He who aspires still higher, and seeks to attain the third degree, or *Nirvana*, throws aside even rags, and remains entirely naked; he eats nothing but rice, and that only once in two days. The name is nearly synonymous with that of Deity, and he is held in nearly equal veneration with the priests and rajas, whose images are worshipped in the temples. At Billicull, or Belligola, the residence of their high priest, they have a gigantic image of Gomat Iswara Swami, the foot of which is nine feet in length, so that the height of the entire statue cannot be less than fifty-four feet; and there is a similar one at Kurcul, near Mangalore. This worship of gigantic images is common to them with the followers of Boodha, whom they also closely resemble in

their theological tenets; nay, Samana and Gaudma, the main objects of Boodh veneration, are enumerated by the Jains among the earliest and most venerated of their priests. On the other hand, they differ from them entirely in being divided into four casts, distinguished from each other by the same privileges and manners as among other Hindoos. The Jains observe also similar penances, carrying them only to a greater extreme. They are also scrupulous to a still greater degree as to causing the death of any living thing, even the minutest insect. The strictest Jains, to guard against this danger, do not eat after sunset; they have always a small broom to sweep the ground before them, and never drink water unless strained through a cloth. The orthodox Hindoos have ceremonies by which any involuntary offence of this kind may be expiated; but the Jains, not allowing the efficacy of these, have no means of relieving their soul from the burden of such a trespass. Like the other Hindoos, they consider it unlawful for the widow to marry again, but discourage the barbarous practice of sacrificing herself on the body of the husband. On the whole, it would appear that while their doctrines and belief closely coincide with those of the Boodhists, their civil and social life is discriminated only by minute shades from that of the Hindoos. They have a system of their own with regard to history, chronology, and physics, of which we need only observe, that its tenets are still more extravagant and absurd than those contained in the orthodox pages of the Vedas and Puranas.

See *Asiatic Annual Register*, Vol. IX.—Dubois on the Manners of the People of India, Lond. 1817.—Ward on the History, Literature, and Religion of the Hindoos. Lond. 1817. (H.)

JAUTS, a people of Hindostan, who have at different times made some figure in its annals. The first historical mention of them occurs at the beginning of the eleventh century, on the invasion of India by Mahmond the Gaznevide. That conqueror found them established on the eastern bank of the Indus, prepared to oppose his passage. For this purpose they had mustered a large fleet of boats, to the number, according to some accounts, of eight thousand. They were completely defeated, however, and driven into the mountainous districts in the interior of India.

From this time the Jauts remained in obscurity, till the reign of Aurengzebe. Churamana, a Jaut of some distinction, collected then some troops of banditti, with whom he began to commit depredations on travellers. Popular and enterprising, he gradually rose from a captain of robbers to be a powerful chieftain, and availing himself of Aurengzebe's absence in the Decan, became the terror of the country round. He had even the audacity, on one occasion, to plunder the rear of that monarch's army; and, when pursued, took refuge among the

JAINS

||

JAUTS.

Jauts
H
Java.

mountains of Narwar, where he eluded all attempts to extirpate his force. Under the growing imbecility of Aurengzebe's successors, the Jauts continually extended their power, till at length, during the weak reign of Mahommed Shaw, and under their enterprising head, Sooraje Mull, it rose to its utmost height. That chief wrested continually new concessions from the weak emperor, till he was able almost to dictate the counsels of the Mogul court. A reverse, however, took place on the invasion of northern India by Ahmed Shaw, the sovereign of Caubul. Sooraje Mull, having opposed that invader, saw his territory overrun, and was obliged to seek aid from the Mahratta power. When the Mahrattas, however, invaded Delhi, the Jaut chief went over to Ahmed Shaw, and offered to atone for former hostility by his services on that critical occasion. The battle of Panniput followed, in which the Mahrattas were totally routed, and their power for the time entirely broken. Ahmed Shaw rewarded the services rendered by his new ally in this hour of need, by the important cession of Agra and its district. Sooraje Mull, and his son Jowalier Sing, made repeated attempts to obtain possession of Delhi, but were always baffled by untoward circumstances. Jowalier Sing was assassinated by an impostor, who had undertaken to initiate him in the secret of the philosopher's stone. He left his son an infant;—a circumstance which, affording an open field to the dissensions of the chiefs, weakened the Jaut power, and rendered it unable to contend with the other fierce competitors for the spoils of the Mogul. In their contests, particularly with Nujeph Khan, they were gradually stripped of all their possessions, and at length reduced to the fortress of Bhurtpoor, with a small surrounding district. When the British power became predominant in this part of India, Runjeet Sing, Rajah of the Jauts, sought security by concluding a treaty with Lord Lake, by which, on engaging to assist Britain against all enemies, he not only retained the internal government of his territories, but was even exempted from paying any tribute. Yet, in 1805, after the defeat of Holkar, he received that chief, with his discomfited army, into Bhurtpoor. The place sustained a most desperate siege, and cost the British army an immense number of lives. At length the Rajah, despairing of effectual resistance, agreed to compel Holkar to quit the place, and to give it up to the British, on condition of retaining the government of his territories, and the fortress of Deeg. He was obliged, however, to pay twenty lacks of rupees, and to give ample security for a more faithful observance of this treaty than of the former.

See *Asiatic Annual Register* for 1802.—Mill's *History of British India*, 3 vols. 4to. Lond. 1818 (b.)

JAVA. The *Encyclopædia* contains a short description of this extensive and important island. Since that article was written, a large mass of valuable information has been communicated to the public in the *History of Java*, by Sir Stamford Raffles, who, in the capacity of Governor of the Island, enjoyed ample means of gratifying his liberal spirit of inquiry; and in the *History of the Indian Archipelago*, by Mr Crawford, late Resident at the Court

of the Sultan of Java;—a work equally distinguished by accurate observation and philosophical reflection. Java.

Of all the islands which compose the great Indian Archipelago, Java, though not the most extensive, is the most fertile, the most populous, and the most improved. Among the two races of people who inhabit the Oriental Islands, distinguished into the brown coloured race, and the Papuas, or Oriental negroes, the natives of Java belong to the former. They are under the middle size, the standard for men being five feet two inches, and for women four feet eleven inches. Their complexion is a yellowish brown, generally without any tincture of red. Of this colour they admire the fair specimens, and their standard beauty is a virgin gold; but they consider the European white as a sickly tint. They have a round face, little black eyes, a small nose, and a large mouth, with thick lips. On the head, beard, and other parts of the body, there is a remarkable deficiency of hair. Compared with the Europeans and Southern Asiatics, they are considered by Mr Crawford as an ill-looking race; but the opinion of Sir S. Raffles is, in this respect, more favourable. Their constitution is healthy, and they seem to attain a longevity equal to that of Europeans. Early marriages are as universal as among other Asiatics, a man being scarcely ever known single at twenty-five, while an unmarried female at eighteen is considered an old maid. The lot of the female sex differs considerably from what it usually is among Asiatics. They are by no means immured with the same jealousy; British gentlemen have even been admitted to visit the harams of the sultans and chiefs, where they were received by the ladies with all the dignified propriety of persons accustomed to mix in general society. To women, the commercial and pecuniary affairs of the family are almost wholly entrusted. Of these privileges and advantages, they are said not always to make the very best use. The right of divorce, with which they are indulged equally with the other sex, is carried by them beyond all excusable limits. It is very common for a woman, before the age of thirty, to have divorced three or four husbands; and Mr Crawford had one pointed out to him who was living with her twelfth. No difficulty occurs in regard to the disposal of the children, who, in Java, are never viewed in the light of a burden. Besides being easily supported, they are usually few in number, a circumstance ascribed to the hard labour which the mothers undergo, and the consequent frequency of abortion. Besides the management of the household, they weave all the cloths worn in the family, and perform various other offices, which in Europe devolve on the other sex. Polygamy is permitted by law, but it is known only among the great; and, even with them, the first wife alone is of their own rank, and mistress of the family; the others occupy a place decidedly inferior. The natives of Java were drawn by their Dutch masters in very dark colours: but the English residents, after careful observation, have described them much more favourably. They are generous, warm-hearted, and susceptible of strong attachments. Their affections of kindred are peculiarly forcible; so that, even in civil

Java.

contests, those fraternal enmities, so conspicuous in other Asiatic states, are scarcely ever observable. The English, who placed confidence in them, found them honest in the intercourse of common life; and they share only in a slight degree those habits of piracy for which the Malay tribes are so notorious. In society they are uncommonly good humoured, courteous, and polite, and scarcely ever seen in a passion, unless on those occasions when they are hurried to the last extreme of violence. These unhappily too often occur, under the impulse of that violent jealousy and revenge, which form their ruling passions. The disregard of human life seems to proceed to an excess among them, scarcely known in any other quarter of the globe. It is stated that, in any part of Java, an assassin may be hired for the moderate sum of fifteen or twenty shillings; but, in general, the injured party conceives it more honourable to decline this cheap mode of redress, and to seek vengeance with his own hand. Some, driven to the extreme of desperation, run furiously into the streets, and kill indiscriminately all whom they meet, till they are themselves overpowered and cut down. This dreadful atrocity, which, by a corruption of the native term, is called "running a muck," is said, however, to prevail, not among the native Javanese, but among the other Malay tribes, resident in the capital.

Religion.

In the ancient religion of the Javanese, which was undoubtedly derived from Hindostan, Siwa, with his family, and Buddha, were the chief objects of adoration. Their temples appear, from the late inquiries of our countrymen, to have rivalled the splendour of those erected in the native seats of their religion. In the course of the fifteenth century, the whole island of Java was, by Arab traders and settlers, converted to Mahomedanism. This faith, however, which is generally observed with so much strictness, is professed here in a very loose and imperfect manner. It need only be observed, that wine and spirits are not only used without scruple on ordinary occasions, but are even sometimes produced at religious festivals. An extreme indifference prevails as to all its outward observances. In return, superstitious credulity prevails to a degree almost unparalleled. A belief in sorcery is universal. If a person write the name of another on a scull, bone, or leg, and suspend it from a tree on haunted ground, where two roads meet, the laws doom to death, himself, his friends, his children, and his children's children. Availing themselves of this credulity, various persons usually start up, in troubled times, as saints, prophets, or as the descendants of one of the ancient kings of Java, and attract a multitude of followers. Christianity has not obtained any footing in Java; and Mr Crayford doubts if it ever will, till the conduct of its Indian professors becomes more conformable to its precepts.

Language.

The Javanese language is the most copious and improved of any used in the Indian islands. It has Sanserit for its basis, but with considerable variations. In the beauty of its written characters, it is not surpassed by any of the languages of Asia. It is distinguished by its vast copiousness as to particular, and barrenness as to general terms. Thus there are

Java

five names for a dog, and seven for a horse, but no general word for an animal. The abstract terms, nature, space, and others of that kind, are entirely wanting. All their literature, as is usual among rude nations, is metrical, and may be divided into lyrical compositions or songs; romances founded on Hindu legends; romances founded on modern story; histories of modern transactions; legal and ethical tracts, chiefly in prose. Of these compositions, the songs, in which feeling and passion are simply expressed, appear to be the most pleasing. The romances consist chiefly of abridged translations of the Mahabarat and Ramayana, from the Hindoo original into a now dead Javancse language, called the *Kawi*. These versions, being free from the endless prolixity of the originals, may be read with greater pleasure. Java had no history previous to the Mahomedan invasion; and even now, its annals consist merely of metrical legends, which being written under the eye of the prince whose deeds they relate, cannot be suspected of very strict impartiality. Besides the rudeness of these compositions, there is an absence of that energy, ardour, and sublimity, which have often characterized the poetry of far ruder nations. This seems justly ascribed to the despotic form of the government, which represses all the nobler sentiments natural to independent man, when individual character is permitted to unfold itself.

The government of Java is more absolute than that of any other part of the Archipelago, and differs little in this respect from the great monarchies of Asia. There is no rank but what emanates from the sovereign; and no bounds are set to the marks of respect shown by inferiors to the higher classes. No individual, of whatever rank, can stand in the presence of a superior, not even the heir-apparent in that of the sovereign. Whenever a chief appears in public, all his inferiors must throw themselves into the posture called *dodok*, which may be rendered by the English term "squatting;" in which they remain till he disappears. Sir S. Raffles describes himself as much annoyed at seeing, in one of his progresses, the whole population of the country quitting their work, and remaining fixed in this uneasy posture so long as he remained in sight. They have a language, or at least a modification of the common language, which must be used by the inferior, in addressing those of higher rank. The revenue of the sovereign, as usual in Asiatic despotisms, arises from the rent of all the cultivated lands in the country, levied in kind, and in the enormous proportion of one-half of the entire produce. This, however, by the allowance of one-sixth for reaping, is reduced to about two-fifths. It is paid, not into the treasury, but by the king assigning to each of his officers and servants a certain number of cultivators, whose rents he is to receive. The Javan farmer is supposed, on the whole, to be more mildly treated than the Hindoo.

Java is the most fertile of the eastern islands. To this, its lofty mountains and its extensive plains equally contribute. The copious streams, descending from the higher regions, not only supply the requisite moisture, but cover the vallies with deposits of

Java. rich soil. Along the foot of the mountains, this is ten, twelve, or even fifty deep, and of the most excellent quality. Farther from the mountains its fertility becomes less conspicuous; but almost every where throughout the island, the combined influence of heat and moisture is sufficient to raise good crops.

Teak. The most important natural production of Java is the *teak*. This valuable timber is produced abundantly only in Malabar, the Birman empire, and Java. It requires a rich soil to come to perfection, and attains to maturity in eighty or a hundred years. On the plain it acquires a larger growth, but is not so hard as when growing on the mountains, where, however, it scarcely thrives more than three or four thousand feet above the level of the sea. The teak of Java ranks in quality below that of Malabar, but above that of the Birman empire. It might become an extensive object of exportation, the forests of Java being sufficient to afford annually 50,000 beams for ship-building, besides an ample supply for minor objects. The Dutch greatly limited this trade by subjecting it to a rigid monopoly. The English adopted a more liberal system, in consequence of which teak soon found its way into the markets of Bengal; but since the recent cession, the old system has been re-established, and the teak of Java has advanced in price 200 *per cent*.

Rice. Of agricultural products, the most extensive and important is *rice*, the eastern staff of life. The industry and skill of the Javanese, not elsewhere conspicuous, appear to considerable advantage in this culture. The implements are not quite so rude as those used in Indostan; and though there are here none of the extensive tanks constructed in the latter country, the brooks and rivers are advantageously employed for the purposes of irrigation. The rice of Java is copiously exported to the other Indian islands, to China, and sometimes even to Europe. It is considered inferior to that of Carolina and Bengal. When the former sells for 18s. a cwt., and the latter for 11s. 3d., that of Java sells only for 9s. 9d. This inferior value is not owing to any original defect in the grain, but to the unskilful modes of husking and drying it. Maize grows in great luxuriance, but is considered an inferior grain, though its culture has of late been considerably extended, in consequence of the scarcity of lands fit for rice. A variety of pulses are raised as green crops, in the intervals between those of rice.

Coffee. Coffee, though introduced into Java only in 1725, has been found admirably suited to its climate, and is become one of the most important articles of culture. It is produced of good quality only upon the sides of the mountains, three or four thousand feet above the level of the sea. The introduction of this plant has been of the greater value to the island, since the lands upon which it thrives are unfit for any other important product. Coffee is exported to the amount of twenty-six millions of pounds, about two-sevenths of the produce of the West Indies. The trade is susceptible of a much greater extension. The coffee of Java, in the European market, ranks with that of Bourbon, both being considered superior to West India coffee.

VOL. V. PART I.

Though the cane be a native of the Indian islands, **Java.** the art of making *sugar* has been introduced from Europe. The rich soil of Java is perfectly suited to *sugar*. this culture, which is reckoned to be carried on there 125 *per cent*. cheaper than in the British West Indies. The produce of Java consists of clayed sugar, which equals or surpasses in quality any other except the Havannah. Hence has arisen an extraordinary demand, which, in the course of a few years, has raised the produce to six times its former amount. In 1818, it was so high as 27,400,000 lbs. The molasses, combined in the proportion of 62 parts with 35 of rice, and 3 of palm wine, yield the arrack for which Java is famous, though it is now made chiefly for internal consumption.

Tobacco, another article unknown previous to European connection, has become a general object of consumption and culture in the Indian islands. Java produces the greatest quantity, sending 5,000,000 lbs. to the rest of the Archipelago, and the Malayan peninsula. It produces, also, a considerable quantity of those birds' nests, the gelatinous substance of which forms the fantastic luxury of the Chinese. The annual export to Canton is reckoned at 27,000 lbs., which bring about L.5, 18s. *per lb*. Cotton is grown in great quantity, though of quality inferior even to that of the neighbouring islands, to which, however, its cheapness occasions a considerable exportation. In Europe, the cotton of Java is not esteemed; and the present glutted state of its markets affords little encouragement to any exertions to fit the cotton of Java for them.

Java does not produce the valuable metals and minerals in any quantity. A considerable quantity of salt is manufactured on its coasts by the simple process of evaporation in the sun. A good deal of saltpetre is also found, though not nearly in the same abundance as in the continent of India.

Manufacturing industry can scarcely be said to exist in Java. Weaving is exclusively practised by the women, who make coarse cloths of cotton, and sometimes of silk, for the use of their families. The trade of a blacksmith is held in high esteem, and considered almost as a liberal profession; chiefly, it is probable, on account of the value attached to the manufacture of arms. Their small boats and barks are made of various and very convenient shapes; but they fail whenever they attempt to construct vessels of any magnitude.

In giving the list of the products of Java, we have given also the articles which it affords for exportation. Its imports are important from the augmentation which they have lately received, and of which they are still susceptible. It appears, by Mr Crawford's statement, that there does not exist here the same inveterate prejudice against European manufactures as in India and China. Since the opening of the free trade, the fine cottons of Britain have, from their cheapness, in a great measure superseded those of Indostan. Chintzes are the favourite article, in which the pattern is of much consequence. The taste of the Javanese is for bright colours, red and green in preference to all others, and next to these yellow and brown; while black is unsaleable. The pattern should be small, filling the ground without crowding

JAVA
||
India.

it. White calicoes and cotton cambrics are also purchased by the natives, to be painted by themselves. Although Java lies under the tropics, its mountainous and maritime situation produce a demand for light woollens. These should be cheap Yorkshire cloths, such as cost at Leeds 5s. to 6s. 6d. per yard. Iron, to the extent of 28,000 cwt., and to the value of £22,500, is annually imported into Java, which is destitute of that important metal. The Swedish is preferred, though British iron has of late been introduced to a considerable extent. Fire-arms and ammunition are most saleable articles, but their export has hitherto been prohibited by European governments. There has been recently a great extension of demand for our glass and earthenware. The tea and silks of China, and the opium of Bengal, form the chief articles of importation into Java from Asiatic countries.

Population. The population of Java, including the small contiguous Island of Madura, was found, by a census taken in 1815, to amount to 4,600,000. Of these, three millions are in the provinces immediately subject to European authority; the rest is subject to the native princes. The principal European capitals, Batavia, Samarang, and Surabaya, contain respectively 60,000, 25,000, and 20,000 inhabitants; the chief native capitals, Surakarta and Yug Yukerta, about 105,000 each. The Chinese, amounting to 94,000, form the most active and industrious part of the population; the manufactures of salt, sugar, and arrack, are solely in their hands. Slavery, in Java, prevails to a much less extent than in the other islands. The slaves do not exceed 30,000; and none of them are native Javans, but obtained by purchase or capture from Celebes or Borneo. The philanthropic measures adopted by Sir Stamford Raffles, with a view to the abolition of the trade, were se-

conded by the chiefs, and productive, to a considerable extent, of the desired effect.

The late changes in the European occupation of Java are of the less importance, as they have ended by all things being replaced in their original state. As Holland, after its annexation to France, became hostile to Britain, the consequence was the reduction, by our naval force, of its most important colonial possessions. On the 4th of August 1811, a British force was landed in Java, and, on the 10th, Batavia was taken by storm. The Dutch general, Janasens, retreated to the eastern extremity of the island, where being pursued and defeated by the British forces, he entered into a capitulation for the general surrender of Java. The British government, in the following year, engaged in a war with the native sovereign, which ended in the cession to us of extensive and important districts. Under the enlightened government of Sir Stamford Raffles, most important improvements were made in the judicial system, the collection of the revenue, and the freedom of trade. A literary society was also instituted, which performed important services in investigating the antiquities and natural history of Java. Meantime, upon the downfall of the French military government, and the restoration of independence to Holland, the faith of former alliances required the restoration of the conquests made from the latter power. This obligation was fulfilled by Britain in its fullest extent. At the close of the year 1816, the Dutch took possession of Java, along with their settlements in Celebes and the Spice Islands.

Recent History.

I N D I A.

Origin of
the East
India Com-
pany.

INDIA, from the rare and precious commodities with which it was known to abound, and from the general belief of its immense wealth, became, at an early period, the favourite resort of commercial adventurers from Europe. The Portuguese had enjoyed its commerce for nearly a century, when the English offered themselves as competitors for the riches of the east. After several unsuccessful adventures, Sir Francis Drake, in 1577, sailed for India, which he reached by Cape Horn, and returned by the Cape of Good Hope, having touched at several of the rich and populous islands which are scattered in the Indian Ocean, and brought back the most favourable accounts of their commerce, and of the friendly dispositions of the inhabitants. He was followed by several other adventurers, some of them of the highest rank, with whose commercial views were combined schemes of predatory enterprise against the Spanish settlements and trade. The first association for a regular trade was formed in 1599, and a capital of above £30,000 was subscribed in 101 shares, which varied from £100 to £3000. This Company at-

ted out four ships to India, which set sail from Torbay in 1601, and returned in 1603, having made a handsome profit on the capital employed. From 1603 to 1613 eight other voyages were undertaken to India, with similar views, and, with the exception of one in 1607, they were all successful, yielding a profit hardly ever below 100, and, in general, above 200 per cent. In 1611, those English fleets, notwithstanding the intrigues of the Portuguese, were favourably received by the Mogul government at Surat, which conceded to them the privilege of establishing factories at Surat, Ahmedabad, Cambaya, and Goga; a duty of 8½ per cent. being imposed on their merchandise in lieu of all demands. (*Mill's History of British India*, Vol. I. Chap. iii.)

It was now resolved to adopt the plan of a joint-Stock stock in place of a regulated Company; and, on these terms, a sum of £490,000 being subscribed, four different voyages were undertaken, the profit on which amounted to only 87½ per cent. The profit on the trade, while each individual acted for him-

India. self, amounted to 171 per cent.—a fact which sufficiently illustrates the superior efficacy of individual prudence over every other principle of management. In 1617-18, a second joint-stock was subscribed to the amount of L.1,600,000; but from the hostility of the Portuguese and Dutch—from the active competition of the latter, in the lucrative trade of the Spice Islands—from the bad management of the Directors at home—and, lastly, from the competition of private adventurers, some of whom had the address to procure the King's licence for a voyage to India, the affairs of the Company fell into great disorder. They petitioned King Charles I. and his council against the new and most alarming grievance of a free trade; but it does not appear that they were reinstated in their exclusive privilege till the reign of the Protector in 1656. A new charter was afterwards received from Charles II, containing the important privilege of making peace or war with the native powers, and of seizing unlicensed persons within their limits, and sending them to England. In 1640, a settlement had been effected at Madras. About the year 1651, owing to the influence of the English surgeons, who had effected some remarkable cures at the Court of Mogul, a licence was obtained, on payment of 3000 rupees, for a free and unlimited trade, with the rich and extensive province of Bengal, and in 1668, the Company received possession of Bombay from Charles II; to whom, on his marriage to the Infanta Catherine, it had been ceded by the court of Portugal. (Mill's *British India*, Chap. iv.)

From this period, the increasing wealth of the nation appears to have supplied the Company more liberally with funds for the Indian trade. In 1668, the value of the exports to India amounted to L.245,000; in 1671, to L.456,000; in 1675, to L.89,000; in 1678, to L.352,000; in 1680, to L.161,700; in 1681, to L.396,000; and, in 1682, to L.740,000. The Company's servants in India, however, involved themselves about this period in hostilities with the native powers, and, in the course of this contest, Arungzebe, the most powerful of all the Mogul sovereigns, was so exasperated by their conduct, that he issued orders for the expulsion of the English from India, and for the destruction of their establishments. The factory at Surat was seized; the island of Bombay was attacked; and the other establishments and factories of the Company were in like manner threatened; and it was only by the most abject submissions that the Company could obtain the restoration of the factories at Surat, and the removal of the enemy from Bombay. So detrimental was this contest to the affairs of the Company, that their equipments continued on a very reduced scale for several years.

Union of the Old and New East India Company. In the mean time, the accumulation of capital in the country subsequent to the reign of Charles I., joined to the growing ardour of the nation for commercial adventure, had given rise to a general impatience of the Company's exclusive privileges, which was heightened and inflamed by the cruel and arbitrary measures pursued for the suppression of the private trade. Doubts began to be suggested as to the legality of restricting the rights of commerce

by royal charter without the sanction of Parliament. Applications were made to the Legislature on this subject, which were favourably received. In these circumstances, a proposition was made for the formation of a new company, which was eagerly adopted; and, in 1693, while both parties were keenly urging their pretensions, the old Company offered to Government a loan of L.700,000, at 4 per cent., for a renewal of their charter, and for the monopoly of the Indian trade secured to them by act of Parliament. They were outbidden by their rivals, who offered L.2,000,000, at 8 per cent., for similar privileges. This latter offer was accepted, and a bill for this purpose was brought into Parliament. The old Company were, at the same time, allowed to trade along with the new, for the space of three years, until 1701, according to a proviso in their charter, that three years' notice should be given them previous to their dissolution. The rivalry of those two companies was the occasion of continual jarring and hostility, both at home and between their agents in India, which proceeded at length to undisguised violence. These disputes were displeasing to the nation at large, because they obstructed a highly beneficial trade, by which great riches, it was generally thought, were brought into the country; and the demand being general for a union of those rival interests, the separate funds of the Company were finally united into one great joint-stock. An indenture triplicate, including the Queen and the two Companies, was signed, to give legal efficacy to this transaction. Considerable differences still remained, which, however, it was agreed to refer to the arbitration of Earl Godolphin, Lord High Treasurer; and, in the mean time, an act of Parliament was passed, ratifying the agreement which had been concluded, and enacting that a loan of L.1,200,000 should, at the same time, be advanced to Government without interest; which, being added to the former L.2,000,000, constituted a loan of L.3,200,000, at an interest of 5 per cent. The Company were empowered, by the same act, to borrow to the extent of L.1,500,000 on their common seal. In 1708, at the time of the union of the two Companies, the official value of all the exports to India amounted only to L.60,915; in 1715, it fell to L.36,997. It afterwards increased, and the average value of the exports for twenty years, from 1708, was L.92,288. *

The domestic trade in India, and more especially the provision of the Company's investment, owing to the general insecurity of the country, required expensive establishments for its support, and a body of experienced servants besides, to collect and to purchase commodities for exportation; an employment which, owing to the poverty and abject state of the natives, and their peculiar customs, involved duties of the most minute and laborious detail. During the decline of the Mogul government, the tranquillity of India was frequently shaken by the contentions of rival chiefs, and the slight security afforded even in the best times to commerce, became in this manner more imperfect. For the reception of goods which it was necessary to collect and store up, that cargoes might always be in readiness for the Company's ships, warehouses were built, which,

lishments of
the Com-
pany

India.

with the counting-houses, and other apartments for the agents and business of the place, constituted the factories of the Company. These factories contained a valuable store of property, which, in the disordered state of India, it became necessary to secure from the rapacity both of governments and of individuals. The factories were therefore strongly fortified, and fortified, their inmates were armed and disciplined, and, for better security, regular troops were occasionally maintained in these mercantile garrisons. In these defensive arrangements of the Company, we may discern the rudiments of their future empire.

The business of the Company in India was, at this time, managed by the three independent presidencies of Bombay, Madras, and Calcutta. The Presidency consisted of a governor and council of nine, twelve, or any greater number of members, as should seem expedient, in a majority of which all power was vested. The members of the council were not excluded from other more lucrative offices, which were, in general, shared among them. These offices were chiefly in the gift of the president, and, by means of his influence, the council were, in a great degree, placed under his control. The governor and council exercised the most ample powers over all the servants of the Company, and with regard to all others, they could seize and imprison them, and afterwards send them to England. The powers of martial law were bestowed on them at an early period, for maintaining the discipline of the troops under their orders; and, in 1661, a charter of Charles II. gave them the power of administering civil and criminal justice according to the laws of England.

From the conclusion of the peace of Utrecht, the country rapidly advanced in prosperity and wealth, and the Indian trade partook of this general improvement. In the year 1708, the imports amounted to L.498,257, from which they increased to L.1,059,759 in 1730. The rate of profit in 1708 was 6 per cent. on a capital of L.8,168,200, from which it gradually rose till, in 1716, it amounted to 10 per cent., at which rate it continued till 1723, when it was reduced to 8 per cent. In India, the policy of acquiring dominion was pursued with perseverance and success. In 1698, the Company had been permitted to purchase the zemindarship of the three towns of Sootanuty, Calcutta, and Govindpore, with their districts; to which was afterwards added, a district, extending ten miles from Calcutta, on each side of the river Hoogly, containing thirty-seven towns. In the year 1732, the annual dividend was reduced from 8 to 7 per cent., at which rate it continued till the year 1744.

A new scene was now about to open in India. The European settlers had hitherto occupied the possessions allotted them by the permission of the native powers, to whom they were subject. But as the ships and military preparations at their different settlements increased, their views gradually became more lofty and independent. In 1744, France and England, first being auxiliaries, became principals in the great European war which was then raging, and the flame was soon communicated to their most distant colonies. In India the two rival powers were

quickly involved in hostilities, which scarcely ever ceased, until, by the ascendancy of the English, the French, after various changes of fortune, were, in 1761, driven out of the Carnatic. An account of these events having already been given in the *Encyclopædia*, under the articles *BRITAIN* and *INDO-TAN*, the following observations will be chiefly confined to the policy adopted by the mercantile sovereigns of India in the internal administration of their newly acquired dominions; and with this view, it will suffice to observe, that, in Bengal, a plan was formed in 1757, in concert with a domestic faction, at the head of which was Meer Jaffer, a relative of the royal family, for the deposition of the reigning Prince Suraja Dowla, who had already waged war against the British, and was averse to their establishment in the country. This plan was accomplished, partly by arms, and partly by intrigue, and Meer Jaffer was raised to the throne of the deposed sovereign. In accomplishing this revolution, the Company's servants, who had imbibed the most extravagant notions of the wealth of India, took care to bargain for enormous sums of money to themselves. The new sovereign, who succeeded to an exhausted treasury, had recourse to the most severe extortions to satisfy the rapacity of his foreign allies. His subjects became discontented and rebellious; his troops mutined for want of pay, and so dissatisfied were the British with his administration, that they dethroned him, and set up Meer Cossim in his stead. The new ruler of Bengal, aware of the tenure by which he held his precarious power, set in motion all the necessary machinery for extorting money from an impoverished people; and he had so far succeeded, partly by a strict and severe administration of his finances, and partly by the most vigilant economy, in restoring the vigour of the government; when every thing was again involved in confusion by the extravagant pretensions and unbounded rapacity of the Company's servants.

In India the transit of goods from one place to another was, under the native governments, subjected to a tax; and upon all the roads, and navigable rivers, toll-houses were erected, where this tax was paid. These toll-houses were multiplied to the great inconvenience and oppression of the internal trade, and as the duties varied in different places, the traders were frequently oppressed by the arbitrary extortions of the collectors. The East India Company had, at an early period, procured an exemption from these duties, for all articles which they were to export, or had imported; and the servants of the Company, who were allowed to engage in the internal trade of the country, frequently endeavoured to abuse this privilege, by claiming an indiscriminate immunity from taxation for all their own goods, which they had neither imported, nor were to export, but which, with a view to the domestic trade of the country, they were transporting from one place to another. This claim was, however, always vigorously resisted, as ruinous alike to the revenue and to the domestic trader; and the native rulers, while they retained their power, always restrained the Company's servants within their appointed limits. But when, by the dethronement of Suraja Dowla, and the elevation of Meer Jaffer, the English acquired un-

India.

Rate of Profit.

Increasing power, and oppressive conduct, of the Company.

India. disputed ascendancy in the government, they broke through all the equitable restraints which had been imposed upon them, and not only engaged largely in the interior trade, but claimed, under the Company's passport, an immunity from all internal duties, not merely for articles of export and import, but for their whole commerce; and, from the general dread of the English name, the keepers of the different toll-houses no longer exacted the public dues on the transit of their goods through the country. In some cases where the demand was made and the goods stopt, the toll-keeper was arrested by a party of Sepoys, and carried prisoner to the nearest factories; and he was frequently exposed to even greater severities, being tied up and lashed. The confusion into which the country was thrown by the violence and injustice of these rapacious intruders may be easily imagined. The native merchant, still burdened with the heavy transit duties which were rigorously levied on him, was undersold in every market by the Company's servants, who, in a short time, engrossed the whole commerce of the country. The unhappy natives were subjected to various other oppressions. It was a common practice of the Company's servants to defraud them both in purchase and sale; to force goods from them at a lower, and to compel them to buy their own at a higher rate than the market price. Nor did the ordinary tribunals of the country afford any refuge from their injustice; for a band of foreign adventurers had usurped the sovereign power, which they rendered wholly subservient to their own schemes.*

Meer Cossim, the ruler who had been set up by the Company, was extremely displeased with the conduct of their servants, and he represented, in the strongest terms, to the President and Council, the enormities to which the private trade had given rise. But the majority of the Council were too deeply interested in these enormities to be much moved by this just appeal of the sovereign in favour of his oppressed people. They all participated largely in the profits of the private trade, and they had no disposition, therefore, to part with or to restrict this lucrative abuse. They even refused to pay 9 per cent. of transit duties on their goods, though this rate was far inferior to that paid by the native traders, and all that they would agree to was, out of their own liberality and free choice, to pay a duty of 2½ per cent. on salt alone. The Nabob, when he heard of the proceedings in Council, and of the injurious treatment of his officers for duly executing his orders, was naturally filled with indignation, and, in these circumstances, he came to the resolution of abolishing all internal duties. There could not possibly have been a more moderate or equitable measure. It gave freedom and equality to all parties; it threw down at once all the restraints to fair and open competition, and gave to the Company's servants the unlimited freedom of trade. This just and liberal policy, however, was far from corresponding with their views, and it ex-

cited among them the most violent clamours. They were discontented at losing so fair an opportunity for amassing enormous wealth. Their conduct (as Mr Mill justly observes) furnishes one of "the most remarkable instances on record, of the power of interest to extinguish all sense of justice and even of shame." (*British India*, Vol. II. Chap. v. p. 201.)

The conduct of Meer Cossim was so highly displeasing to the majority of the Council, that they resolved to dethrone him, and he, on the other hand, made preparations for war, which he saw was inevitable. The war ended in his discomfiture and flight, first to the Nabob of Oude, and afterwards to the Rohilla country. Meer Jaffier was chosen by the Company's servants to be the nominal ruler of Bengal, on the well understood condition of subservience to their views. A treaty was concluded, confirming the immunity which they claimed from all internal duties, with the exception of 2½ per cent. on the article of salt, while those duties were re-imposed on the goods of all other merchants. Large presents were bargained for, and other payments to a great amount, as compensation for losses alleged to have been sustained by the Company's servants, in the course of their illicit interference in the domestic trade. These sums (which were estimated at first, at ten, soon afterwards mounted up to fifty-three lacks of rupees, equal to about L.596,250) were rigidly exacted, while large payments to the Company were still undischarged;—while the public finances were sinking under the burden of an expensive war, and great sums had been borrowed by the Company from its servants, at an interest of 8 per cent.; and while, with all these aids, supplies were wanting both for the war and for the investment; the Company's ships frequently returning, in consequence, half loaded to Europe.

Meer Jaffier dying in 1765, his son, Jaffier, was chosen by the Company's servants in India to succeed him. From each successive sovereign, it was the custom of the electors to exact not only a large donation, but also an extension of power and privileges, so that the native ruler was at length left in possession of little more than mere nominal authority. It was now resolved by the English that they should take upon themselves the whole charge of defending the country, and that they would only allow the Nabob a few troops for the sake of parade, or for other necessary purposes; while, in regard to the civil government, he was to choose a deputy with the advice of the Governor and Council, on whom the whole internal administration of the country should be devolved. So completely was the government under the control of the English, that the accountants of the revenue could not be appointed without their approbation.

During this important revolution, which gave to the British such entire ascendancy in Bengal, the Directors in Europe were distracted by the contradictory reports of their affairs, transmitted to them from India. Being alarmed by the eagerness of their

* See Ninth Report of the House of Commons on India Affairs; also a letter of Meer Cossim, dated Bactergunge, May 25, 1762, which states, that the inhabitants who refused to sell to the Company's servants were flogged or confined.

India.

servants to embark in expensive wars—by their unwarrantable and rapacious proceedings in regard to the private trade—and by the general disorder and embarrassment of their affairs, they resolved to appoint Lord Clive to the supreme government of Bengal. They at the same time reprobated, in strong terms, the rapacity and tyranny of their servants. In a letter to the Governor and Council they observe,—"Your deliberations on the inland trade have laid open to us a scene of the most cruel oppression."—"The poor of the country," they continue, "who used always to deal in salt, betel-nut, and tobacco, are now deprived of their daily bread by the trade of the Europeans, whereby no kind of advantage accrues to the Company, and the government's revenues are greatly injured." (See Mill's *British India*, Vol. II. p. 216.) The Directors, accordingly, issued the most peremptory instructions for the prohibition of the inland trade of salt, betel-nut, and tobacco, or rather of the monopoly held by the Company's servants, by which the country was so cruelly oppressed. The practice of receiving presents from the native rulers and princes, which had been carried to a great extent, was also prohibited. At a general meeting of Proprietors, however, it was urged, in opposition to those wise and salutary restrictions, that the "servants of the Company in India ought not to be deprived of such precious advantages, which enabled them to revisit their native country with independent fortunes." This reasoning convinced the majority of the Proprietors, and a recommendation was moved, in consequence, to the Directors, to re-consider their resolution in regard to the private trade. The Governor and Council were therefore instructed, after consulting with the Nabob, to form a "proper and equitable plan for carrying on the inland trade." (Mill's *British India*, Vol. II. p. 217.) In other words, they were to contrive how they could oppress the country, and yet adhere to the rules of equity. This transaction places in a very strong light the corrupt nature of the Company's government. It was admitted on all hands, that it was by extortion and rapine, *i. e.* by compelling the oppressed inhabitants both to purchase and sell at prices fixed by the Company's servants, that such profits were gained, and that they were enabled to return to Europe with enormous accumulations of ill-gotten wealth. It was, indeed, as we have just seen, acknowledged by the Directors, that the poor of the country were deprived of their daily bread by the trade of their European servants, who monopolized every profitable channel of business; yet, with these facts before them, we find the sovereigns of India delivering over their oppressed subjects to the rapacity of their servants, for the avowed purpose of enriching them with the spoils of the country.

Policy of Lord Clive.

Lord Clive assumed the supreme power in India in May 1765. At this period the servants of the Company, in defiance of the peremptory orders of the Directors, still persisted in all the ruinous practices connected with the inland trade; and, in place of abolishing these, and thus remedying some of those abuses of which he so violently complained, Lord Clive entered into a partnership for the monopoly of salt; of which large quantities were

accordingly purchased and sold, for a profit of 45 *per cent.*, divided among three of his own dependants,—his secretary, surgeon, and another friend, for whom he wished, as he expresses it, to realize a fortune. The plan of a more extensive monopoly, including salt, betel-nut, and tobacco, the chief articles of consumption in the country, was afterwards devised, to be carried on exclusively for the benefit of the superior servants of the Company, among whom the profit, after setting apart £100,000 *per annum* to the Company, was to be divided according to their rank in the service. At the time this corrupt scheme of monopoly was established, the Select Committee were in possession of peremptory orders from the Directors for its abolition; but these orders, under various pretences, they delayed to carry into execution till September 1768.

India.

While the servants of the Company in India were thus eagerly devising the means of enriching themselves, their masters were frequently reduced to great pecuniary wants. But, in the midst of all those pecuniary embarrassments, the most flattering accounts of the Company's affairs were circulated in Europe, and on the subject of Indian opulence there was a general disposition to credulity. The splendid acquisition which the Company had made of the territorial revenues of Bengal, the political events in which they had been involved, and the immense fortunes with which a few individuals had returned to Europe, confirmed the general delusion, and inflamed the impatience of the proprietors of East India stock to participate in the inexhaustible treasures of their new dominions. In pursuance of these views, the dividend on their stock was raised from 6 to 10 *per cent.*: India stock rose to 263 *per cent.* A higher dividend was called for, and it was in vain that the Directors represented the heavy debts of the Company, and the general embarrassment of their affairs. The Proprietors refused to listen to such disagreeable representations, and at a general court they voted a dividend of 12½ *per cent.* for the year 1767. The attention of government being now directed to the Company's affairs, this vote was rescinded by act of Parliament, and the dividend limited to 10 *per cent.*

In the mean time, every day's experience was refuting the fallacious expectations of annual treasures from India. It was represented, that the territorial revenue of the Company would prove an inexhaustible source of wealth; and the Directors and Proprietors, in giving ear to these golden promises, of which their servants had been very liberal, were the dupes of their own credulous avarice. Hitherto, however, promises were all that had ever been received from India. So far from possessing any surplus revenue, the servants were involved in debt for the current expences of their government; they drew largely on the directors, but they remitted little; and the whole of this complicated scheme of trade and sovereignty laboured in consequence under such pecuniary difficulties, that the directors, to avert a public bankruptcy, were compelled to apply to the bank for a loan of £400,000, and afterwards of £300,000. In consequence of this state of things, so different from the pleasing fancies of unbounded wealth, with which the proprietors of the Company, and the coun-

re-Parliamentary Regulation of the Company's Affairs.

India. try at large, had been amused, great discontent, and a violent clamour was raised against the Company's servants in India, who, by their profusion or corruption, had failed to realize those golden dreams. The affairs of the Company were at length brought under the consideration of Parliament by the minister, who introduced two acts for the regulation of their affairs, a full account of which, and of the discussions which took place in consequence, will be found in the *Encyclopædia*, under the articles BRITISH and COMPANIES. It may suffice to observe here, that these acts vested the administration of the affairs abroad in a Governor-General, with four councillors, rendering the other presidencies subject to that of Bengal, and establishing a supreme court of judicature at Calcutta, consisting of a chief justice and three other judges.

pany the ern- of and Ma- sement of Land Revenue. Although the ascendancy of the English had for some years been thoroughly established in Bengal, and although they were formally invested in 1760 with the sovereignty of the country, its affairs were still administered in the name of the native prince, and according to the forms and policy of the ancient constitution. Justice was still dispensed by the native courts, and by the Nabob's officers; the revenues still flowed through the same channels into the public exchequer; and all transactions with foreign powers were carried on under the same authority as formerly. But such was the increasing power of the English, that the government, so far as regarded the protection of the people, was dissolved. Neither the Nabob nor his officers dared to offer any opposition to their sovereign will; and the tribunals of justice, far from being a refuge to the oppressed, became subservient to the rapacity of the Gomastahs, or Indian agents, employed by the Company's servants, and were converted by them into most efficacious instruments for oppressing and plundering the people.

The Directors had been long dissatisfied with the proceedings of their servants, and with the produce of the land revenues, which had fallen far short of their expectations, and they now resolved to put an end to the double administration of the Nabob and the Company; and dispensing with the empty name of the former, to take upon themselves, ostensibly as well as really, the entire care and management of the land revenues. But they had no right conception of the important consequences which were involved in this measure; they were not aware, that it was an innovation on long established habits and prejudices, and on the settled policy of the country; that it unsettled the basis of property as well as the administration of civil and criminal justice; and that it was calculated to produce a greater revolution in domestic manners, than if the country had been transferred by conquest from one sovereign to another. In order to explain this point, it will be necessary briefly to describe the state of property and manners which prevailed in India under its native rulers.

Under the Mogul government the public revenue was derived from a general land-tax, and the regular payment of this tribute was the tenure by which property was generally held throughout the empire. The lands were possessed by different descriptions of owners or occupiers, under the titles chiefly of *Zemindars*, *Talookdars*, and *Ryots*. The nature of the Zemindary tenure has been a standing subject

of controversy among the Company's servants; some insisting, that under the Mogul despotism, the Emperor was the sole proprietor of the lands, and the Zemindar, a species of steward or factor, appointed by the Government to collect and superintend the land revenues; and, after reserving a suitable portion for his own maintenance, to remit the surplus to the treasury; while others maintain that he was proprietor of the lands, and that he was only bound to the state for a stipulated tax or quit rent. Without entering into this controversy, which is rather abstract and speculative than of any practical consequence, it may be observed, that the Zemindars had lived for centuries in great splendour on the produce of their lands, which had quietly descended under the existing tenure through successive generations; that they had the power to sell, to alienate, or to mortgage; and that so long as they paid the annual tribute to government, they enjoyed secure possession of their estates. Under a despotic government arbitrary ejectments might no doubt occur; but these were rare, and they were universally regarded, both in law and usage, as the illegal outrages of abused power. It is admitted, on all hands, that these rights belonged to the Zemindars, and the only point that still remains in dispute (and it does not appear very material) seems to be, whether, according to the theory of the Mogul constitution, the receipt of the land-tax by the sovereign, or of his allotted share of the produce by the Zemindar, entitled the one or the other to the title of proprietor of the land.

The Zemindars, being bound to the state for the revenue, were necessarily invested with the power of collecting the land-tax from the subordinate landholders and tenants. They united, in this manner, legal authority with the possession of property, while, as judges and magistrates, they administered both civil and criminal justice, and were held responsible for all crimes committed within their respective boundaries. In the criminal court held by the Zemindar, he had the power of inflicting all sorts of penalties, and even capital punishments, on reporting the case, before execution, at Moorskedabad. There were various other descriptions of occupiers or tenants, such as the Talookdars, &c. who had hereditary claims on the produce of the soil; and while the government looked to the principal landholders for the discharge of its demands, the inferior occupants and tenants were bound, each to his immediate superior, for their several proportions of the stipulated tax. The Ryots were the cultivators of the soil, who claimed the hereditary right of occupancy, which they transmitted to their children, and from which, so long as they paid their demands to the state, they could not be lawfully ejected.

The country was divided into villages or districts, comprising some hundreds or thousands of acres of arable and waste land. The district was divided into a greater or smaller number of shares, according to circumstances, and was either cultivated by the joint labour of the whole inhabitants, or each individual was allotted a separate share for his own maintenance. In the one case, the whole population were bound, jointly and severally, for the common rent, while, in the other, each individual paid his separate

India.

share. There were various distinctions of rights among the inhabitants, some of occupancy, some of ownership, of which exact accounts were kept in the public register of the village, as well as by the parties interested.* Every village had also its establishment of public officers and tradesmen. These consisted of the *Potail*, or head inhabitant, whose business it was to superintend the affairs of the village, to settle disputes among the inhabitants, to attend to the police, and to the collection of the public tax; the *Curnum*, to whom it belonged to keep an account of the cultivation and produce of the land—to register the proprietors of the village, and to attest all deeds of sale, transfer, or assignment; the *Boundaryman*, who preserves the limits of the village, or gives evidence of them, in case of dispute; the Priest, the Schoolmaster, the Astrologer; the Smith, the Carpenter, the Potter, the Washerwoman, the Barber, the Cowkeeper, the Doctor, the Dancing-Girl, the Musician, the Poet, who were each rewarded for their labours out of the produce of the village lands. The amount of their shares on the gross produce is estimated at $5\frac{1}{2}$ per cent. The collectors were allowed 10 per cent., and the remaining proportion of the crop was divided between the sovereign and the cultivator.

It was not the policy of the Mahometan conquerors, when they invaded India, to innovate materially on the management of the land-revenues, or even to oppress the cultivators by heavy impositions. It was in 1573, during the reign of the Emperor Akbar, that they completed the conquest of the country; and a general rent-roll was at that time formed for all Hindostan, by Rajah Torrel Mull, minister of finance to the emperor, as well as a scheme of division fixing the separate proportions of districts and villages. According to this plan, a settlement was concluded, by which the amount of the tax was fixed at 1 crore, 49 lacks, 61,482 rupees, or nearly L.1,683,166.† This assessment does not appear to have been increased by subsequent monarchs, since its amount, according to the authenticated rent-roll of the Mogul treasury, was, in 1728, L.1,425,000; which is only a variation of L.75,000 from its original standard, in the course of two centuries. Under the Mogul government, however, the inferior occupants and cultivators of the land possessed no adequate security for the possession of their rights; and though, during the vigour of the monarchy, the Zemindars might be restrained by the dread of punishment, or by their regard to laws and immemorial usages, from gross oppression, yet many abuses afterwards took place, under which the share of the crop left to the Ryots was reduced to a bare subsistence.

In the reign of Aliverdi Cawn, who succeeded to the throne in 1741, the land-tax imposed by Akbar was augmented by various arbitrary assessments. To the original ground rent other taxes were added, some permanent, and others occasional. These consisted

of duties on the transit of goods through the country, of taxes on shops and manufactures, and of fines and exactions of various sorts; and the Zemindar, who was bound to the state for the revenue, was empowered in proportion to those augmented demands to increase the contribution of his tenants. In the reign of Meer Cossim, who was set up by the Company's servants in 1761, these oppressions were carried to a still greater height. He was raised to the sovereignty on the well understood condition of subservience to the rapacity of the English; he had engaged to pay them large sums on his elevation to the throne, and it was essential to the fulfilment of his iniquitous bargain that he should plunder his subjects. His government is accordingly described as being in the highest degree illegal and oppressive. In place of adhering to the assessment fixed by the ancient policy of the empire, he instructed his agents to ascertain, by exact survey, the produce of the land, and he claimed for the treasury the whole surplus which remained, after allowing a bare maintenance to the cultivators.

After the dethronement of this prince, the country was by no means improved under the growing ascendancy of the English. The state of society which prevailed in Hindostan arose from the mixed operation of a peculiar system of laws, customs, manners, religion, and policy; such an artificial structure required to be nicely and skillfully handled, in place of which it was lacerated in all its delicate parts by the rude hand of foreign interference. The English were ignorant even of the language of the people whom they had brought under their sway, and whom they now attempted to govern; and though they might know generally, that the public revenues were derived from an impost on land, they were entirely inexperienced in the usages of the country, and in the financial details of the Mogul government. They knew not through what an infinite variety of petty channels the land revenue was brought together, and at last poured into the imperial treasury. With what effect, therefore, could they interfere in such complicated details; how could they decide between the claims of justice and of fraud; how could they judge of cases connected with the peculiar usages of the country, and with all those minutiae of local manners with which no foreigners can ever become thoroughly acquainted? The Company's servants, involved in such a labyrinth of complex concerns, possessed no clue to guide them to any equitable issue. Supposing their views to have been honest, they wanted intelligence to give them effect, and although they could enforce submission to their decrees, the country, under their usurped and ill-directed authority, presented one vast scene of anarchy and oppression. Nor was there any tribunal to which the oppressed could fly for relief; the Nabob, the nominal ruler of the country, being totally without power, and consequently unable to maintain

India.

* See *Appendix to the Fifth Report* (printed by order of the House of Commons, 1812), from the *Select Committee on the Affairs of the East India Company*, p. 714, where, in the extracts from the Report of Mr Place, the reader will find a detailed view of the different rights and privileges, some of ownership, some of property, claimed by the inhabitants of the village.

† A lack of rupees is 100,000, a crore is 100 lacks, or ten millions. The rupee is worth about 2s. 3d.

India. the authority of his tribunals against the masters of the country. (Mill, Vol. II. p. 309.)

All those evils were readily ascribed by the Directors to the misconduct and rapacity of their servants, who, in their eagerness to make fortunes for themselves, totally neglected the interest of their masters; and this was no doubt true. But the objection of the Directors was, that they plundered the country for their own benefit, and not for that of the Company. Had the wealth acquired found its way into the public treasury, and been remitted to Europe in the form of a large investment, no such heavy complaints would have been made. The hope of receiving a surplus from their territorial revenues was, indeed, a delusion long and fondly cherished by the proprietors in this country. They expected to share among them the wealth of India. The land and labour of the country was to be laid under contribution for the benefit of its mercantile proprietors in Europe. The new sovereigns of India could never relinquish the notion of *profit*, the original object of their association. Their conceptions were never elevated to the true dignity of their situation. The glory of a sovereign consists in the felicity of grateful millions, and this is the only true and legitimate end of all government. But the East India Company were intent on profit,—on enriching themselves at the expence of their subjects; and the duty of the servants to their masters consisted in sending home a large investment. They were to possess themselves of as large a quantity as possible of the produce of the country, giving nothing in return, and to send it to Europe, to be shared among the proprietors; and it was, accordingly, the boast of successive administrations how well they had succeeded in this matter,—not how happy they had made their subjects,—but how much of their property they had taken from them and sent to Europe.

To realize the hopes of a large surplus revenue from India, the territorial revenues were racked to the utmost. The revenue contracted for in 1765 amounted to L.1,607,826; in 1766 and 1767, it amounted to L.1,713,677, from which deductions were afterwards made, as it was found impossible to collect it. The revenue, however, actually realized, exceeded the surplus formerly paid into the Mogul treasury when the country was in a flourishing condition. But the methods by which it was collected were ruinous to the country. The landholders, failing almost universally in their engagements, were left to the mercy of the revenue-officers, by whom they were grievously oppressed. In many parts the villages were deserted by the cultivators, and the land was left desolate. All those evils were still further aggravated by a grievous famine which prevailed in Bengal, in the year 1770, by which it is computed that about one third of the inhabitants perished. But, in the midst of all this misery, the revenue was still violently kept up to its former standard. The deficiencies occasioned by the famine were re-assessed on those who survived this calamity, and so strictly were they levied, that the land revenue for that year exhibited an increase above that of the year preceding. The ruinous effects of this heavy

exaction are stated at length in the different letters from the Governor-General to the Directors. In a letter, dated 3d November 1772, he observes, "It was naturally to be expected that the diminution of the revenue should have kept an equal pace with the other consequences of so great a calamity; that it did not, was owing to its being violently kept up to its former standard." He then describes the method by which this was accomplished, which was by "an assessment upon the actual inhabitants of every inferior division of the lands, to make up for the loss sustained in the rents of their neighbours, who are either dead or have fled the country." "The tax (he continues) not being levied by any fixed rate or standard, fell heaviest on the wretched survivors of those villages which had suffered the greatest depopulation, and were of course the most entitled to the lenity of government. It had also this additional evil attending it, in common with every other variation from the regular practice, that it afforded an opportunity to the farmers, or sheidars, to levy contributions off the people under colour of it, and even to increase this to whatever magnitude they pleased, since they were in course the judges of the loss sustained, and of the proportion which the inhabitants were to pay to replace it." To the same effect, Mr Middleton, one of the superintendents of the public revenue, observes, "When a very considerable portion, supposed even a third of the whole inhabitants, had perished, the remaining two-thirds were obliged to pay for the lands now left without cultivators. The country has languished ever since, and the evil continues enhancing every day. The first remedy, without the adoption of which all other measures will be fruitless, is an universal remission of some considerable portion of the revenue throughout the provinces. Such remission should have been made immediately on the famine. Its not taking place, then, has made it more and more necessary every day; and the longer it is delayed the more ruinous the consequences must be to this country and its revenue."

To correct these evils, numerous feeble remedies were devised. For the purpose of superintending the native officers, both in the collection of the revenue and in the administration of justice, which were intimately connected with each other in the Mogul Empire, the Company's servants were stationed in different parts of the country with the title of supervisors, and, to add to their security, two councils with authority over the supervisors were established, one at Moorsshedabad, and another at Patna. "One of the most important duties of these supervisors was to procure information respecting the amount of the land revenues; the manner of collecting them; the amount of the cesses, or arbitrary taxes; the origin and progress of those modern exactions; and also to inquire concerning the regulations of commerce and the administration of justice. The reports made by these supervisors concurred with all the other evidence received as to the wretched and oppressed state of the natives. "The Nazims (they observed) exacted what they could from the zemindars and great farmers of the revenue, whom they left at liberty to plunder all below; re-

India. serving to themselves the prerogative of plundering them in their turn, when they were supposed to have enriched themselves with the spoils of the country."

Consequences of the assumption of the management of the land revenue.

Such was the condition of the country when the Directors resolved to supersede the native government in the management of the land revenues. This resolution was adopted without any consideration how far their servants were qualified for the task of legislators among a people with whose manners, habits, and laws, they were totally unacquainted; and the latter, on their part, seem as little to have distrusted their qualifications for the duties assigned them. They resolved to make a settlement of the land revenues for five years, commencing from the year 1772. For this purpose, a committee of the board, consisting of the President and five members, named the "Committee of Circuit," was appointed, who were to make a journey through the country, and were empowered to receive proposals for a new lease of the lands, first from their ancient possessors, if their offers were deemed unsatisfactory, they were to be let by public auction to the highest bidder. These persons proceeded in their circuit through the country, publicly advertising and letting in farm, for the highest rent that could be obtained, the estates of such as hesitated to contract for the assessment proposed. A great proportion of the landed property throughout Bengal was thus exposed to auction; and, in the general sale, the former owners and the great nobility of the country were outbidden by adventurers, to whom property was acceptable on any terms, and were generally dispossessed of their lands, from the surplus produce of which a provision was assigned them by the indulgence of the revenue committee.

The supervisors who had been stationed in the different districts were invested with the necessary powers for the collection of the revenue, and were henceforth denominated collectors. A native officer was to be joined with them, under the title of duan, to confirm and to check accounts, and to assist in all those multifarious details which were intelligible only to a native. Various regulations were adopted to check the exertions of the collectors; but the governor and council express their regret that it was not in their power wholly to remedy this evil. (Mill's *British India*, Vol. II. p. 312.) Under the Mogul government, the duty of collecting the revenues and of administering justice was united, as formerly mentioned, in the person of the zemindars. The new scheme for the management of the revenues subverted this ancient order of things. The zemindar was superseded both as collector and as judge, and his place was supplied by two courts, the one for civil, the other for criminal proceedings, established in each district. In the criminal court the few collectors of taxes was to act as president, to be assisted by Mahometan officers, the *cawans*, and the *muttee*, and by two Mohlavis, as interpreters of the law. The civil court consisted, in like manner, of the collector as president, assisted by the duan and other officers of the native court. Two supreme courts were, at the same time, established at Calcutta, for the review of the inferior courts, both civil and criminal. To one of these all capital cases were reported, and were ultimately referred to the governor and

India. council; who, finding the labour too great, restored, in 1774, this branch of administration to the nominal Nabob, and carried back the court to Moorsshedabad. It appeared that, for a long period before this, the administration of criminal justice was wholly at a stand. In the new arrangements all disputes about property, not exceeding ten rupees in value, were referred to the head man of the district to which the parties belonged.

In considering those regulations, the question naturally occurs, how these supervisors, who were now to act in the double capacity of collector and judge, became qualified for the discharge of such important functions? In all other countries, it is only by a previous course of laborious preparation, that any one is qualified for the office of a judge, and to appoint an unqualified person would be reckoned both dangerous and absurd. But how much more dangerous and absurd was it to appoint un instructed persons to act as judges in a foreign land, with whose language they are but imperfectly acquainted, and of whose laws, manners, and customs, they are thoroughly ignorant? If, among a comparatively rude people the mode of proceeding be loose and arbitrary,—if there be no books of written law, or of precedents to govern judicial decisions, which must consequently depend on the imperfect lights and analogies afforded by manners, religion, or customs, the incapacity of a foreigner for the discharge of such nice duties becomes even more glaring. By disposing of the administration of justice in this manner, it was clear, that the judicial duties would either be neglected, or that they would still be performed as before, and with no increased chance of amendment by native officers. This new arrangement was, therefore, like many others, a useless innovation on the established practice of the country. There is another weighty objection to the union in one person of the duties of collector and judge, namely, that it was in the collection of the duties that the grossest oppression had been committed; the powers of the collectors being frequently perverted to the most iniquitous ends. Under this new project those who sought redress from the courts of justice, met with their oppressor in the capacity of judge. He judged in his own case and of complaints brought against his own conduct. Justice was in this manner an empty name, unless it was supposed that the judge would pronounce himself an oppressor.

Under the five years' lease on which the land revenue had been farmed in 1772, the country was grievously overtaxed. The revenues fell into a heavy arrear the very first year, and the lands were let on a progressive rent. To collect the outstanding balances, and to force up the revenue to its standard, a host of extortioners was, under the name of *Aumils*, or collectors, let loose upon the afflicted country. But the rents contracted for by the farmers of the revenue were greater than they could pay, and, notwithstanding all their efforts, the arrears continued to increase. On the five years' lease, they amounted to a sum equal in value to L.1,454,277, which was judged to be wholly irrecoverable; while, during the same period, the sums remitted, even under the rigorous management of public farmers, amounted to L.1,336,451. Nor was this the only

India. Evil arising from the mal-administration of the Company's servants. The zemindars, who are admitted on all hands, even by those who advocate the sovereign's right to the possession of the soil, to have lived in splendour on their hereditary possessions,—in all cases to have possessed the powers of magistracy within their district, and where the territory was large, to have exercised a species of sovereignty,—were either despoiled of their estates, or, where they were induced, by a hereditary attachment to their possessions, to engage for the rent proposed, they were overwhelmed with taxes which they could not pay, and were thus involved in poverty and ruin. Where the zemindar was himself the farmer of the revenue, he exercised the same extortion on his inferiors which was applied to himself; where a money jobber, who had no interest whatever in the property of the tenants, was the farmer, there was no limit to his extortion and cruelty.

The defects in this system for the administration of the land revenues soon began to disclose themselves; and the rulers of India, whose government was one continued innovation, immediately resolved to make another considerable change in the state machinery, which they had just set in motion. They abolished the superintendence of the collectors, and the country, with the exception of Chittagong and Tipperah, being formed into six grand divisions, viz. Calcutta, Burdwan, Moorshedabad, Dinazepore, Dacca, and Patna, a council was appointed for each of the last five, consisting of a chief and four senior servants, to whom were transferred the powers and duties of the collectors. They were to preside in the courts of justice, and to superintend the collections; and, in subordinate districts, they delegated their powers to naibs or aumils, who were natives, and who were appointed, like their superiors, to collect and to judge in all cases under the value of 10000 rupees. The empty privilege of appeal was, as formerly, reserved to the unsuccessful suitor in the provincial courts, and to superintend the whole collections of the country, a grand revenue-office was established at the presidency. The district of Calcutta was placed under the peculiar superintendence of a committee of revenue, consisting of two members of the Council and three inferior servants. These regulations, which were declared to be temporary, and only preparatory to something more permanent, failed as usual in all their important objects. The defective administration of justice among the natives was admitted and complained of by all parties, and the peace of the country was in consequence disturbed by the general prevalence of robbery and other enormous crimes. The truth is, that the new arrangements had subverted the ancient institutions and local manners of the country, and had thus left a void in its internal economy which the Government was in vain endeavouring to fill up.

The lease of the lands expired in 1777; and, after various suggestions and consultations, it was resolved that the rent should be regulated by the average collections of the three preceding years, and that the lands should be let, not by auction, but by an agreement with their ancient possessors in preference to other competitors. The liberal views of Mr Francis, who proposed that, in lieu

of the monopoly of salt and opium, a moderate duty should be imposed on those articles, and that a long series of oppression should thus be terminated, by giving freedom to trade, were rejected by the Governor-General. In pursuance of the plan proposed, the lands were let from year to year until the necessary arrangements could be completed for the system which was now to be adopted of a permanent land-tax.

The attention of the British Parliament had frequently been directed to the state of our Indian possessions; and to the transactions of the resident government; and, in 1784, a new system was established in Britain for the control of the local administration, under which, Lord Cornwallis, who was chosen Governor-General, was specially directed by the act of Parliament, as well as by instructions from the Directors and the Board of Control, "to inquire into the alleged grievances of the landholders, and, if founded in truth, to afford them redress; and to establish permanent rules for the settlement and collection of the land revenue, and for the administration of justice founded on the ancient laws and local usages of the country."

Lord Cornwallis, on his arrival in India, did not deem matters fully ripe for the execution of the proposed plan, namely, the permanent settlement of the land revenue. On this important subject he found a great difference of opinion among the most intelligent of the Company's servants. Neither the nature of the land tenure, nor the rights of the different orders of people, who shared among them the produce of the soil, were sufficiently understood. All that was distinctly known was the amount of the revenue; but whether it was too high or too low was still a point in dispute among the English in India. In such wide diversity of opinion, the Governor-General was, naturally anxious to proceed with caution, and to delay for some time the plan of a permanent settlement. The lands were, in the mean time, let from year to year through the agency of the district collectors, and information on which to found a more durable arrangement was diligently sought from every source.

In 1789, Lord Cornwallis had matured his plans for the permanent settlement of the land revenues. This he now conceived to be the only measure that could retrieve the country from its present condition, which he described to be wretched in the extreme. "I am sorry (he observes) to be obliged to say, that agriculture and internal commerce have for many years been gradually declining; and that at present, excepting the class of Shroffs and Banyans (bankers and merchants), who reside almost entirely in towns, the inhabitants of these provinces are advancing hastily to a general state of poverty and wretchedness. In this description I must even include every zemindar in the Company's territories; which, though it may have been partly occasioned by their own indolence and extravagance, I am afraid must also be in a great measure attributed to the effects of our former system of management."—"I may safely (says he) assert, that one third of the Company's territory in Hindostan is now a jungle, inhabited only by wild beasts." So thoroughly persuaded was Lord Cornwallis of the necessity of a permanent settlement of the land re-

venties, with a view to the improvement of the country, that the agreement with the landholders, at first made for ten years, was afterwards declared unalterable; and the zamindars of Bengal, Bahar, and Orissa, were formally constituted legal and perpetual proprietors of their respective estates on the payment of a fixed rent to the state. The ten years, or, as it is called, the *Decennial settlement*, was completed in every district in 1793, and was afterwards extended to the conquered countries.

Plans of
Lord Corn-
wallis re-
garding the
civil and
criminal
Judicature

Along with the decennial settlement Lord Cornwallis also introduced other important reforms in the administration of civil and criminal justice. The union of the duties of tax-gatherer and judge had produced, as might have been expected, the most glaring abuses. The tax-gatherer not only officiated in many cases as his own judge, but while the duties of the two offices happened to interfere, which was often the case, it invariably happened that the one was discharged by the neglect of the other. It was now proposed to separate those incompatible functions, and to establish in each district of the country, and in all the considerable towns, a civil court, in which one of the Company's servants, higher in rank than the collector, should act as judge, to be assisted by a register, and one or more of the junior servants of the Company, and also by a native expounder of Hindu or Mahomedan law. The judge was authorized to refer all cases of inconsiderable importance to his register, from whom there lay an appeal to himself; and for determining suits regarding personal property, not above the value of 50 rupees, courts of native commissioners were established in every district, to decide in a summary manner. From this inferior court of law there lay an appeal to the court of the district, whose decision was final, except in cases of real property, or in the event of the decision of the inferior court being reversed. A new scheme of appellate jurisdiction was also introduced. All causes involving property above the value of 1000 rupees might formerly be appealed to the Governor-General in Council. This court, however, was found to be useless to the natives, whose disputes never involved property to such an amount, and who, as the court was established in Calcutta, could not afford the expence of such distant litigation. To remedy this grievance, Lord Cornwallis established four tribunals of appeal; one in the vicinity of Calcutta, and one at Patna, Dacca, and Moorshedabad. In these three the Company's servants were to sit as judges, to be assisted by a register, and one or more of the junior servants of the Company, and by three expounders of native law. To these, which were styled provincial courts, the privilege of appeal was eventually given from all the decisions of the inferior tribunals. To complete these arrangements, a court of supreme jurisdiction was established at Calcutta, composed of the Governor-General, and the members of the superior council, with suitable assistants both English and natives. The former exaction of 25 per cent. by the judge on all litigated property was abolished, as well as the impost on the commencement of the writ, and all fees of court.

Such were the arrangements adopted by Lord Cornwallis for the reformation of the civil judicature

India

in India. The criminal department he describes as being replete with still more disgraceful corruption. In a letter to the Directors, dated 17th November 1790, he observes, "Your possessions in this country cannot be said to be well governed, nor the lives and property of your subjects to be secure, until the shocking abuses, and the wretched administration in the criminal department, can be corrected. Anxious as I have been to apply a speedy remedy to evils so disgraceful to government, so ruinous to commerce, and, indeed, destructive to all civil society, it has still appeared to me to be so important as to make it necessary for me to act with great circumspection." For the purposes of criminal judicature, four tribunals were established, in which the judges of appeal in the provincial courts were appointed to act, and were provided with the same assistants, as in the civil courts. They were to make regular circuits through the country holding a session for jail delivery at the four principal cities of Calcutta, Patna, Dacca, and Moorshedabad, every month, in the district of Calcutta four times, and in the remaining districts of the country twice in the year. The judges in the four courts of appeal were to form two courts of circuit. The inconvenience of devolving both the civil and criminal business on the same judges was soon heavily felt, and, in 1797, after some previous arrangements, which had been found inadequate, two of the judges were specially appointed to the business of the civil appeal court, while only one was left for the business of the circuit. In addition to these arrangements, a criminal tribunal, of supreme jurisdiction was established at the seat of government, composed in the same manner as the supreme civil court of the Governor-General and members of the Supreme Council.

In regard to the plan for the permanent settlement of the land revenues, which demands our first consideration, it may be remarked, that, in the imposition of a land-tax, the great danger is, not that it be too small, but that it be too large, and this evil ought more especially to have been guarded against in framing an assessment that was to be fixed and invariable. Lord Cornwallis, in calculating that permanent possession, on payment of an unvariable tax, would afford a sure encouragement to cultivation, did not sufficiently consider that this altogether depended on the amount of the tax. The invariable rate of a tax is a benefit to a country exactly as it is moderate or otherwise. In the one case, it is satisfactory to know that it cannot be increased, while, on the other hand, the invariable rate of an oppressive tax is a great additional calamity, as it shuts out from the country all hope of relief. Here, then, was one obvious and capital error in the scheme, namely, that a permanent land-tax was imposed without any equitable standard to fix its amount. The legislators of India had not yet acquired the necessary knowledge of the country for such a measure. They had no data on which they could, with any certainty, adjust the tax to the capacity of the soil; and, after long discussions, it was at length fixed at the average amount of the collections for the last three years. But it had been a general complaint, that the country was overtaxed; and to this cause was ascribed its misery and decline

generally of
our Indian
Government

India. From this high standard of taxation, no systematical reduction had ever been made. Arrears, which had been long accumulating, and which could not be recovered, had, indeed, been remitted; but every method of extortion had been practised in order to realize as large a revenue as possible; and the country was now charged with a permanent assessment, founded on the actual revenue of those years. The invariable rate of the tax was, in this case, no benefit to the country; and, in order to receive the advantages supposed by Lord Cornwallis to arise from permanent possession, he should have assured himself of the moderation of the tax imposed. In place of this, it was exorbitant, and greater than the land could bear; and this radical defect, even if there had been no other, would have ensured the failure of the plan. The zemindar, who was bound, in the first instance, for the public tax, depended, for the means of discharging it, on the produce of his rents; and the state, by imposing an immoderate tax on him, laid him under the necessity of practising similar extortion on all below him. The example of the government was a general warrant for extortion, which, once begun, would necessarily descend from the proprietor to the lowest tenant.

There was another important defect in the plan of the decennial settlement, namely, that it seemed to rely entirely on the exertions of the zemindars for the improvement of the country. No attention was given to secure the under-tenants and ryots in the hereditary privileges which they claimed in the soil. As they varied in different places, and depended on different rules, the subject appeared to involve details too troublesome and intricate for European management; and the important task of settling with the ryots was, therefore, devolved on the zemindars, with a mere general recommendation to be guided by the custom of the place, and to give the ryot a written copy of his lease. According to this plan, it was the great proprietors only who had any permanent interest in the lands, while the inferior proprietors and tenantry were at the mercy of the principal landholders, who might exact from them whatever they pleased. The under-tenants and cultivators, in this ill-defined state of their rights, had no interest whatever in the improvement of the soil; being well assured that, however abundant the produce of the soil might prove, they would be left nothing more than a bare maintenance. But it is not agreeable to experience, that the cultivation of any country was ever materially forwarded by the exertions of its great lords. On the contrary, it is their character generally to be inactive, wasteful, and improvident, while the improvement of the land is invariably the work of the cultivators and tenantry, to whom, however, the plan held out no sort of encouragement. Though humanely intended, therefore, it was calculated to entail ruin upon the higher classes of landholders by the tax which it imposed on them; while by necessitating them, and, at the same time, giving them the power to oppress all below them, in order to satisfy the exorbitant demands of the state, it necessarily had the effect of extending this ruin downwards to the lowest tenant. Its effects have entirely corresponded to the view of its principle.

It soon appeared that, in order to realize the revenue, it would be necessary to sell the lands, and this evil once begun continued to increase. The revenue was not punctually paid, and for the recovery of outstanding balances lands to a great amount were at stated times exposed to auction. In the year 1796-7, the lands advertised for sale bore a rent of 2,870,061 sicca rupees (L. 232,027), and those actually sold yielded an annual rent of 1,418,756 rupees (L. 164,576). In 1797-8, the quantity of land sold bore a rent of 2,274,076 rupees (L. 255,839), and it is observed in the *Fifth Report*, p. 56, that "among the defaulters were some of the oldest and most respectable families of the country;" "the dismemberment of whose estates," the report continues, "at the end of each succeeding year, threatened them with poverty and ruin, and, in some instances, presented difficulties to the revenue officers in their endeavours to preserve undiminished the amount of the public assessment." In order to check those evils, several alterations were made from time to time by Lord Cornwallis. But they appear to have been unavailing, and, in the year 1802, in a report from one of the collectors, we have the following melancholy picture of the state of the country:—"All the zemindars," it is observed, "with whom I ever had any communication, in this and in other districts, have but one sentiment, respecting the rules at present in force for the collection of the public revenue. They all say, that such a harsh and oppressive system was never before resorted to in this country; that the custom of imprisoning landholders for arrears of revenue was, in comparison, mild and indulgent to them; that though it was no doubt the intention of government to confer an important benefit on them, by abolishing this custom, it has been found by melancholy experience, that the system of sales and attachments, which has been substituted for it, has, in the course of a very few years, reduced most of the great zemindars in Bengal to distress and beggary, and produced a greater change in the landed property than has perhaps ever happened, in the same space of time, in any age or country, by the mere effect of internal regulations" (*Fifth Report*, printed in 1812, p. 60.) In another part of the same document, the collector, after commenting on a regulation then recently introduced, observes, "Before this period (1799), complaints of the inefficacy of the regulations were very general among the zemindars, or the proprietors of large estates; and it required little discernment to see, that they had not the same powers over their tenants which government exercised over them. It was notorious, that many of them had large arrears of rent due to them, which they were utterly unable to recover; while government were selling their lands for arrears of assessment." The collector adds, "Farmers and intermediate tenants were, till lately, able to withhold their rents with impunity, and to set the authority of their landlords at defiance. Landholders had no direct control over them; they could not proceed against them, except through the courts of justice, and the ends of substantial justice were defeated, by delays and cost of suit." To the same purpose, Sir Henry Strachey observes, "That the men

India.

of opulence are now all men of yesterday; that the greatest men formerly were the Mussulman rulers, whose places we have now taken, and the Hindoo zemindars. These two classes are now ruined and destroyed." (See *Answers to the Interrogatories of Government*, dated 30th Jan. 1802.)

One cause which undoubtedly contributed to the ruin of the zemindars, was the want of any effectual method of enforcing their claims, against the small tenants. For the purpose of duly collecting the revenue, the public officer was empowered to proceed against defaulters by a summary process,—and to attach and sell, by public auction, the zemindar's land for the discharge of arrears; while against the under-tenants, the zemindar had to seek redress by an ordinary suit at law, which was both tedious and expensive. To heighten this evil, the courts of justice were overloaded with a long arrear of undecided causes, so that no decision could be expected, before the lapse of years. In the district of Burdwan, the undecided suits were said to amount to 30,000, and the probability of a decision in any suit was estimated to exceed the ordinary duration of human life. The zemindar, in this manner, while he was compelled to pay, by the prompt and efficient process of government, was left to seek redress from his tenants through a labyrinth of endless litigation, and the knowledge of this impediment to justice gave great encouragement to the tenants to refuse payment of their rents. The ruin of the zemindar, therefore, was the inevitable consequence of those measures, which levied on him a heavy assessment by the most summary process, while he was restrained from levying on his tenants the means of its discharge. The zemindar was the channel through which the land revenue flowed into the treasury. He paid what he received, reserving a small surplus for himself; but to pay what he did not receive was impossible. The injustice, then, and the folly of the present measures, consisted in the means adopted to make the zemindar pay, while no means were given him of making others pay to him; in establishing a regular drain on the zemindar's treasury, and at the same time in withholding from him the means of insuring an equally constant supply. These regulations were universally complained of, and on the justest grounds. In an address from one of the collectors to the board of revenue, in behalf of the zemindar of Burdwan, who had in vain applied for redress to the civil courts, it is observed, that he (the zemindar) begs leave to "submit to your consideration, whether or not it can be possible for him to discharge his engagements to government with that punctuality which the regulations require, unless he be armed with powers as prompt to enforce payment from his renters, as government had been please to authorise the use of, in regard to its claims, on him; and he seems to think it must have proceeded from an oversight, rather than from any just and avowed principle, that there should have been established two modes of judicial process, under the same government; the one summary, and efficient for the

satisfaction of its own claims; the other tardy and uncertain in regard to the satisfaction of claims due to its subjects; more especially in a case like the present, where ability to discharge the one demand necessarily depends on the other demand being previously realized."

The system which impoverished the zemindars was equally ruinous to the ryots. It was the practice of the zemindar to contract for a certain rent with a land farmer, who subdivided the land into smaller portions, and let it to a variety of inferior tenants. To this head farmer, it appears that a written agreement was given, according to the regulations; but the under-tenants were left, without any security, to the mercy of their superiors. It is well known, and admitted by the servants of the Company, that the ryot, even when he receives written agreements from the zemindar, is liable to indirect oppressions which no law can remedy; and though, owing to the expence and delay in the administration of justice, he could retaliate on the zemindar, by refusing payment of his rents, this privilege could be of little advantage to him, while it tended still farther to widen the breach between the landlord and the tenant, and to add to the hatred, strife, and violent distraction of interests by which the community was now, as it were, torn in pieces. To remedy the grievances which the zemindars suffered from the evasion of payment by their tenants, it was enacted in 1799, that they might have recourse to the same summary process against defaulters, as was tried by the government against themselves. They were empowered to seize the property of their tenants for arrears, previous to any legal judgment, or any proof of the justice of their claim. This regulation gave to the zemindars the power of unbounded oppression, against which the ryot had no redress, as he was effectually shut out of the courts of justice, by the enormous expences of law proceedings.* It was undoubtedly just that the zemindar should have the same efficient process for enforcing payment as was used against himself; but such was the unhappy condition of India, under the unskilful management of strangers, that every plan of reform seemed only to increase the general disorder. Her rulers wanted intelligence for the delicate task of domestic legislation; their schemes were crude and inapplicable, nor could they ever mould the various and jarring interests of the Indian community into any consistent scheme of civil order; so that, though they were continually patching their imperfect work, it still bore the same incongruous character, and the cure of one evil was constantly followed by an irruption of other and worse evils from some other quarter.

The institutions of Lord Cornwallis, for the administration of civil and criminal justice, appear to have been equally unsuccessful with his finance measures; and it soon appeared, as has been already stated, that the new courts of judicature had more business than they could manage, and such an arrear of undecided cases accumulated, that the course of

* All the collectors invariably bear testimony to the oppressions of the zemindars, after the passing of the regulation of 1799.

India.

India. justice was nearly stopt. In this dilemma, the costs of suit were raised for the purpose of discouraging litigation; and this expedient being found ineffectual, they were raised a second time. To place justice out of the reach of the poorer and more numerous class, by laying a heavy tax on it, was indeed an easy and effectual method of discouraging litigation. It was, in fact, a denial of justice,—a direct refusal to hear the complaints of the poor, who might, therefore, be harassed for ever after with impunity. Notwithstanding this discouragement, however, the evil went on increasing, and at last amounted to an almost total dissolution of civil order. As no decision was to be procured before the regularly constituted tribunal, every man began to arm himself in his own quarrel, and the country thus became the scene of bloody affrays between armed individuals unflinchingly left without any other resource for the decision of their differences. In some of those conflicts 4000 or 5000 persons were arrayed on each side, and many lives were lost. In a letter of the Court of Directors, dated October 1814, it is observed, “As to affrays respecting the possession and boundaries of lands and rents, this has been long a serious evil, and must, we conceive, have existed in a greater or less degree in every part of the country.”—“These affrays,” continue the Directors, “which often lead to homicides and wounding, have been very naturally ascribed by several of the judges to the difficulty of obtaining judicial redress.”* In the district of Tirhoot, where the public peace had been frequently disturbed by those private feuds, the judge, for the division of Patna, observes, that they chiefly “arose from the accumulated arrears of suits,” and “that the parties finding a delay in obtaining redress, had resorted to force.”† Mr. Melville, also a judge in the division of Dacca, expresses himself to the same purpose. “With respect to affrays (he observes) attended with homicides and wounding, it is known that those disorders arose from attempts to retain by force possession of lands, or rents of lands, to which the different parties alleged separate claims.” The same person afterwards states, that “in Chittagong, they (meaning these quarrels) had not only been frequent, but violent; that the police authority had been often resisted, and in one instance overpowered; that it would be wrong to disguise the length of time a claimant must wait, with the sacrifices he must make, before the decision of a civil court can be obtained.”

We shall now briefly advert to the system of penal judicature and police established by Lord Cornwallis; the object, in this case, being to give security to the people by the suppression of crimes. With reference to this object, however, the scheme has notoriously failed. Since the year 1793, India has become a prey to disorders of every sort, and to the worst of crimes. Violence and depravity seem to have overspread the land, and to have produced an almost universal dissolution of morals among the people. The crime of robbery, accompanied

with murder, had risen to a most alarming height in India, and was prosecuted with a degree of union, perseverance, and cruelty, inconceivable to those who live in the civilized communities of Europe.

Robbery is a regular profession, which is handed down from father to son; and the decoits, or gang-robbers, are formed, as the title implies, into powerful confederacies, and make their irruptions on the peaceful country with a force which it is vain to resist. They are described by Mr Hastings as “a race of outlaws, who live from father to son in a state of warfare against society, plundering and burning villages, and murdering the inhabitants.” In the year 1772, the robbers are mentioned by the Committee of Circuit, and stated to be “not like robbers in England, individuals driven to such courses by sudden want; they are robbers by profession, and even by birth; they are formed into regular communities, and their families subsist by the spoils which they bring home to them.

All the reports of the judges employed in the administration of criminal justice concur in representing the deplorable prevalence of the atrocious crimes of gang-robbery and murder. Sir Henry Strachey, writing on this subject in 1802, observes, that the crime of decoity (that is, robbery by gangs) has increased greatly since the British administration of justice. Another judge, writing on the same subject in 1808, observes, “That decoity (gang-robbery) is very prevalent in Rajeshahye has been often stated. But if its vast extent were known; if the scenes of horror, the murders, the burnings, the excessive cruelties, which are continually perpetrated here, were properly represented to government, I am confident that some measures would be adopted to remedy the evil. Certainly, there is not an individual belonging to the government, who does not anxiously wish to save the people from robbery and massacre. (Mill, Vol. III. p. 311.) He afterwards adds, that such is the state of things which prevails all over Bengal, and as to his own particular district, he expresses his persuasion that no civilized country ever had so bad a police. To the same purpose, Mr Dowdeswell, the secretary to the government in 1809, observes, in a Report which he drew up on the general state of Bengal. “Were I to enumerate only a thousandth part of the atrocities of the decoits, and of the consequent sufferings of the people; and were I to soften that recital in every mode which language would permit, I should still despair of obtaining credit, solely on my own authority, for the accuracy of the narrative.” *Robbery, rape, and even murder itself (he continues), are not the worst figures, in this horrid and disgusting picture. An expedient of common occurrence with the decoits, merely to induce a confession of property, supposed to be concealed, is, to burn the proprietor with straw or torches, until he discloses the property, or perishes in the flames. And when they are actuated by a spirit of revenge against individuals, worse cruelties, if worse can be, are perpetrated by these remorseless criminals. If the informa-

† Ibid. p. 22.

India.

tion obtained is not extremely erroneous, the offender, hereafter noticed, himself committed fifteen murders in nineteen days; And volumes might be filled with the atrocities of the decoits, every line of which would make the blood run cold with horror." (*Fifth Report*, p. 603.)

It would far exceed our limits to trace in detail the cause of these evils, which necessarily arose out of the very nature of the government now established. The truth is, the British were never qualified to act as legislators in India. They were too ignorant of the habits, manners, and character of the people to meddle with their institutions, on which, however, they were continually innovating. By altering the old mode of settling the land revenues, they compromised the rights of the different classes of landholders and occupiers. Strife and contention immediately ensued, litigation burst upon society like a flood, the civil courts were overwhelmed with suits which they could not decide, and the people, desperate from a denial of justice, were involved in furious affrays with each other in prosecution of their rights, or, being driven from their lands, they had recourse to robbery for a subsistence. Business was thus, from various sources, accumulated in the criminal courts, which being encumbered with the delay, the expence, and all the tedious formalities of the English practice, proceeded with their decisions at much too slow a pace for the wants of the country; and the evil in this manner daily increased. The mischief of this delay was twofold; 1st, It allowed criminals, during the long interval between their apprehension and trial, to prepare the certain means of their escape, by the suborning of false witnesses, who, in the gross dissolution of morals which now prevailed, were always to be readily procured, and in any number; and, 2dly, It entailed a grievous hardship on the innocent, great numbers of whom were crowded into jails with the worst of felons, there to wait until the tardy hand of justice should bring them relief.

The inefficient state into which the police had fallen was also one cause of the general prevalence of crimes. By the ancient institutions of the Mogul government, ample means were provided for the preservation of the public peace. In every village a permanent body of guards and watchmen was maintained, whose business it was to assist in all the subordinate details both of the revenue and police—to convey the rents of the ryot to the district collector—to watch those ryots who were in arrear—to guard their crops from depredation—to act as guides and protectors to travellers—to collect information of any offences committed—and to report the arrival in the villages of suspicious persons. For these various services they had grants of land rent-free, or on very easy terms. Besides this standing force of guards and village watchmen, the zemindar, who was at the head of the police, and was held responsible for all crimes committed within his boundaries, had under his orders a large body of *pykes* or armed constables, whom he could call out in aid of the police service, either for the apprehension of offenders, or to prevent breaches of the peace. These establishments, though they had fallen into a state of disrepair at the time of the permanent settlement in 1793, and though they were frequently perverted from their

India.

original purposes, yet existed in all parts of the country, and the police force was found to be in great efficiency and strength. The zemindary of Burdwan, a tract of country 73 miles long by 45 broad, which was in the highest state of cultivation, and well stocked with inhabitants, maintained a body of 2400 village watchmen, who were distributed under their respective chiefs among the different villages, for the double purpose of protecting the inhabitants, and of procuring information; besides 19,000 *pykes* or armed constables, who were liable to be called out, under the orders of the zemindar, in aid of the police. In place of improving upon those ancient establishments which had taken root in the country, which were interwoven with the frame and texture of Indian society, and which were, generally speaking, efficient, though frequently perverted from their original purposes, Lord Cornwallis demolished the whole structure. According to his new scheme of police, the zemindary constables were disbanded, and their lands, which were allowed them in lieu of pay, were resumed, i. e. were seized by government. The country was divided into districts of 20 miles square, over which a native police officer, or *darogah*, was placed, with 15 or 20 armed men under his orders; he was assisted also by the village watchmen, and such of the zemindary constables as were still retained in the public service. It was soon found, however, that the new police officers could not effectually call out this array in aid of the civil power. They wanted the personal consideration of the zemindars, who had been long looked up to with respect and reverence as the hereditary aristocracy of the country. The system proved, therefore, eminently inefficient, nor were the officers employed under the new plan found to be less corrupt than the disbanded constables of the zemindars. The merits of the plan appear to be pretty fairly estimated in the *Fifth Report*, p. 71, in which it is observed; that the head police officers, and "the inferior officers acting under them, with as much inclination to do evil, have less ability to do good, than the zemindary servants employed before them." How vain was it to imagine, that any better materials could be found for the regulation and government of the country than those which the country itself afforded! To complain of them was to complain of the general state of society out of which they were produced; and to throw them away, because they are corrupt or otherwise imperfect, evinces an ignorance of the legislator's province, which is not to create materials, but to make the best use of those which are provided to his hand. Herein, then, consisted the error of the British legislators. They cast from them the only efficient instruments which were to be found for the government of the Indian community, while they had nothing to substitute in their place; and their plans, when tried in practice, were accordingly found to be idle theories, at variance with the whole frame and order of the society for whose use they were intended.

The pernicious consequences of thus rashly subverting the ancient establishments of the country were soon displayed in the alarming increase of crimes. The disbanded zemindary constables, whose lands were seized, were deprived of the means of

living, and they necessarily betook themselves to theft and rapine for a subsistence. The country became infested with gangs of robbers and murderers, whose horrid cruelties struck terror into the peaceable inhabitants, while lesser crimes also became more frequent. The police was inadequate to the detection of offenders; the courts of justice to their conviction; and, among other evils, a host of false witnesses now arose, amid the general corruption of morals, who swore in the teeth of each other, perplexing all judicial proceedings, and confounding the innocent with the guilty. For remedy of these complicated evils, various expedients were resorted to. Among others, a feeble attempt was made to revive the ancient powers which the zemindars had over the police; but this was attended with so little success that it was abandoned in 1810. In 1808 a superintendent of police was appointed. In a view of concentration, as was stated, in his report, all the information which might be obtained from different quarters, and of giving unity and vigour to the measures adopted for the apprehension of offenders; and as a last resource, a regular establishment of police spies, called *gopendras*, was organized, and placed under a species of superintendents, called *gudwars*, the office of the first being to point out the robbers, that of the latter to apprehend them. Notwithstanding all these measures, crimes of every description appear to have gone on increasing, and, in a minute of Lord Minto, dated November 1810, it is observed, "that a monstrous and disorganized state of society existed under the eye of the sovereign British authorities, and almost at the very heart of that government to which the country is entitled justly look for safety and protection; that the mischief could not wait for a slow remedy; that the people were perishing almost in our sight; that every week's delay was a doom of slaughter and torture against the defenceless inhabitants of very populous countries." The Directors, in whose letter of the 28th October 1814 this passage appears, confirm the truth of the statement by the following brief observation:—"That this representation of the late Governor-General is not too highly coloured, would appear from the minute of Mr Jansden, and the reports of Mr Secretary Dowdewell, forming also part of the proceedings in regard to Mr Ernst."*

The new scheme of organizing a body of professed spies in the service of the public, while, in some cases, it was of public benefit, was, in other respects, highly detrimental to the peace of the community. Those spies, and more especially their superintendents (*gudwars*), became, in many cases, the pests of society. They took advantage of the power which they possessed of apprehending suspected persons, to extort money from them; and frequently, under threats of immediate apprehension, they laid under contribution all classes indiscriminately. It is stated, in a letter of the Directors, dated October 1814, on the authority of Mr Dick, a circuit judge, that "whole

villages are put under contribution, or subjected to the rapacity and spiteful machinations of the vilest members of society."† In some cases, the innocent were brought to trial, and convicted, on suborned evidence, procured by these wretches.

Among the other causes of these evils may be enumerated the incapacity of Europeans to officiate as judges in a society so peculiarly constituted as that of India, with the usages and manners of which, as well as with the general character of the people, they remain to this day in a great measure unacquainted. This is a fact which is deeply regretted by all the most experienced servants of the Company, from Sir John Shore downwards. Europeans are sent out to India with the sole view of amassing a fortune. They have no interest in the country from which they draw such important benefits. They know nothing of its habits and manners—never mixing with the natives in their ordinary business or amusements—and never attaining to more than a theoretical knowledge of their characters. With such qualifications, they begin to officiate as judges, how miserably ill-appointed for such an office their own experience quickly teaches them. They soon find the difficulty of appreciating or understanding even the most ordinary transactions of a society, with the rules and principles of which they are entirely unacquainted. What is intelligible by intuition to a native is a mystery to them; and it is easy to conceive how these difficulties must be accumulated on them in any long process of criminal judicature, involving a train of circumstantial, and frequently of contradictory evidence. It is not, as every one knows, on the mere naked testimony of a witness that a judge entirely relies; it is the tone, the manner, the living evidence of expression and character, which impresses upon testimony the stamp of truth; which carries conviction to the mind; and saves a judge from the miserable dilemma of being blown about by every wind of opposite evidence. These discriminations are, however, far too nice for a European judge in an Indian court, and he frequently knows not what to believe. He cannot, by any judicious cross-examination, extort the truth from contradictory witnesses. In any train of questions involving the peculiar usages of the country, his stock of knowledge is soon exhausted. A story which hangs together in all its main circumstances, may yet be inconsistent in some of its minute and delicate points. But a European can never detect inconsistencies which are wrapt up in the veil of local manners. He lies, in this manner, at the mercy of every perjur'd witness who chooses to practise upon his ignorance. The truth of this statement is illustrated and confirmed by the concurring reports of many of those who have acted in this trying situation. Sir Henry Strachey, whose reports to the supreme government abound in most just, enlightened, and comprehensive views of Indian society and manners, observes, that "nothing is more common,

* See *Papers relating to the Police and to the Administration of Civil and Criminal Justice in Bengal, Fort George, &c. from 1810 to the present time*, printed in 1819, p. 24.

† *Papers printed by order of the House of Commons*, 1819.

even after a minute and laborious examination of evidence on both sides, than for the judge to be left in utter doubt, respecting the points at issue. This proceeds chiefly from our very imperfect connection with the natives, and our scanty knowledge, after all our study, of their manners, customs, and languages. Within these few years, too, the natives have attained a sort of legal knowledge, as it is called, that is to say, a skill in the arts of collusion, intrigue, perjury, and subornation, which enables them to perplex and baffle us, with infinite facility."—"We perhaps judge too much by rule—we imagine things to be incredible, because they have not before fallen within our experience. We make not sufficient allowance for the loose, vague, and inaccurate mode in which the natives tell a story,—for their not comprehending us, and our not comprehending them. We hurry, terrify, and confound them, with our eagerness; and impatience."—"We cannot (says the same discriminating observer) study the genius of the people in its own sphere of action. We know little of their domestic life, their knowledge, conversation, amusements, their trades and castes, or any of those national and individual characteristics, which are essential to a complete knowledge of them. Every day affords us examples of something new and surprising; and we have no principle to guide us, in the investigation of facts, except an extreme diffidence of our opinion, a consciousness of inability to judge of what is probable or improbable."—"The evil I complain of is extensive, and, I fear, irreparable. The difficulty we experience in discerning truth and falsehood among the natives, may be ascribed, I think, chiefly to our want of connection and intercourse with them; to the peculiarity of their manners and habits, their excessive ignorance of our characters, and our almost equal ignorance of theirs." The following passage, from the same document, gives a striking view of the inefficiency of European judges. "The evidence on every trial convinces us, that innumerable robberies and murders, that atrocities of the worst conceivable kind, are committed; and that very often the perpetrators are before us; yet do we find ourselves, from causes of the nature above described, constrained to let them loose again, to prey on society; or, at the utmost, to direct that they be discharged, on giving security for their good behaviour."—"The judge of circuit is from day to day engaged in trying large gangs for robbery and murder, and letting them go; and the country continues to be overrun with them, to a degree truly deplorable." (*Answers to Interrogatories of Government, 30th January 1802. Fifth Report.*)

It is well known that, according to the rules of the Company's government, no European is allowed to acquire landed property in India; and that all colonization of the country is studiously discouraged. The European rulers of India could not possibly pursue a more weak and pernicious policy, by which all the other errors of their administration are aggravated; which marks their own jealousy of their subjects, and evinces a disposition to hold possession of the country by any means, however exceptionable. The effect of the Company's government

in India, as appears from the preceding review of its measures, has been to destroy the hereditary aristocracy of the country. All the great families have disappeared, under the rigid exactions of revenue to which they were exposed; their estates have been sold, and they are confounded among the mass of the people. The extinction of this important order of men, and the want of that natural influence which they possessed, is severely felt in every branch of the public management. The business of the revenue, the magistracy, and police, have, as has been shown, fallen into a state of almost irreparable disorder; and these evils are, by all the most experienced servants of the Company, and by the Directors at home, ascribed to the degradation and ruin of the ancient gentry and landholders, who had great authority and respect among the people, and who were universally looked up to as the guardians of civil order. On this subject, Mr Stuart, judge in the Benares division, in a Report to Government, reasons with great force and clearness, and observes, that the extinction of the aristocracy "may be traced throughout the country as one principal source of the disorders which prevail." (*Fifth Report, p. 571*) The great problem, therefore, in the government of India, is to devise the means of re-establishing, in the country, a body of resident gentry, qualified to undertake the management of its internal affairs; and for this purpose no policy seems so effectual as the encouragement of European settlers. If this policy were adopted,—if Englishmen were allowed to acquire land, and taught to consider India as their home, they or their descendants would gradually become naturalised to the climate,—they would be compelled to mix with the natives in their ordinary transactions, and the succeeding generation familiar with the language, manners, and character of the natives, might be qualified for the important duties which are now so inadequately discharged. At present the government of India is composed of a small body of foreigners, who have no interest in the welfare of the country, and who only visit it for the purpose of engrossing, from their rightful owners, every post of honour or profit. It is a strange, anomalous, and insolent domination of the few over the many; it has no tie of sympathy to connect it with the people; it draws no support from the natural feelings and affections of mankind, but derives its strength mainly from the knowledge of its power. It is a singular spectacle to see a whole people, through the agency of foreigners, excluded from all honourable competition for public rewards. A proscription so universal must produce the most unfavourable effects on the national character. By narrowing the sphere of ambition, we diminish the incentives to active exertion—we take away from mankind the motives which prompt them to cultivate their faculties—we weaken the animating principle of all improvement—we relax the moral tone of society, and thus pave the way for the progress of vice and disorder. All accounts accordingly agree that the state of morals in Hindostan has not been improved under the rule of the English. "The decline of morality," says Lord Moira, in his judicial minute, dated 2d October 1815, "is stated to be a subject of reproach against us by all the natives whom birth or education have inspired

India. with concern for the good order or well-being of society." This is imputed to the decay of religious endowments and public seminaries; and to the decline, also, of those moral sanctions connected with custom, religion, and prejudice, which have been gradually relaxed under the ascendancy of the British law. But the monopoly of power, emolument, and honour, in the hands of a few, by constituting the majority a degraded class, must have also had its share in producing those unfavourable effects on the character of the people. Mr Stuart (already alluded to, whose Reports on the state of India abound in the most masterly views of the state of property and manners,) expresses this opinion in the strongest terms: "As we proceed (he observes), these provinces will soon present the singular spectacle of a great empire, the government of which rigidly excludes its subjects from every object of fair ambition, which, in the pursuit, could stimulate men to cultivate their faculties, or, in the possession, enlarge their understandings and elevate their minds. The natives may accumulate wealth as merchants, they may be proprietors of land; but these occupations, as they are managed in this country, have no great tendency to raise the character. Beyond them, with the rarest exception, there is nothing to which the people can aspire, higher than the command of a platoon of seapoys, or the possession of some petty civil office, insignificant in its functions, and paid with a salary hardly adequate to a bare subsistence. My speculation may have perhaps misled me, but I am persuaded that very unfavourable effect from these causes, may already be traced, in the habits of our native subjects, and their long continuance must, I think, infallibly end in reducing the whole population to one ignorant, grovelling, litigious, and profligate herd."

The Directors of the Company in Europe, as soon as they were informed of these vices and disorders in their Indian government, displayed the most praiseworthy zeal in their endeavours to remove them. Far from blaming the freedom with which they were exposed, or seeking, by palliations, to evade the truth, they listened to the representations of their servants, and, in many cases, followed their judicious and enlightened suggestions. One of their first cares was to re-establish the vigour and efficiency of the police. It was soon found that the system established in 1793, not being connected in any degree with the institutions or local manners of the country, was ill adapted to its end; and that the subversion of the ancient establishments, on the ruin of which it was founded, had been attended with the worst effects, and had paved the way for all the disorders and evils with which the country had been afflicted. To restore the ancient institutions of the country is now, therefore, the policy of the government; and, for this purpose, they are endeavouring to revive, for the public service, the ancient array of village watchmen and zemindary constables, formerly disbanded. In many cases, their efforts have been attended with success. A new energy has been infused into the police; and this, joined to the activity of the local magistrates, has had the effect of diminishing the crime of gang-robbery; though, in some districts, this crime still prevails, and conti-

nues to spread dismay through the peaceful country. It does not appear that there has been any decrease of other offences, or that the morals of the people have been in any degree improved. This desirable effect, indeed, if it takes place, must be the work of time; and a long period must elapse before, even under the best institutions, the effect of former errors can be done away. For the improvement of the people, the village schoolmasters have been everywhere encouraged; and, for the same laudable purpose, other seminaries are about to be instituted. The civil courts, according to recent accounts, still continue to be overloaded with an arrcar of undecided causes. To remedy this defect, assistant judges have been appointed; and it has been proposed to have recourse to the effectual assistance of the natives in the judicial business of the country. Those judicious arrangements, aided by the zeal of the Directors at home, and by the great ability employed in the local government, may certainly check those alarming disorders by which the country has been distracted. But the evils which afflict the Indian community have continued too long, and are now too deeply rooted, to be easily removed.

From the year 1805, when a general peace was established by Lord Cornwallis, to the year 1813, when Marquis Hastings assumed the government, the political relations of the Company with the native powers had undergone little alteration. The tranquillity which prevailed was, however, more apparent than real; and it was scarcely to be supposed, indeed, that the widely extending domination of a foreign power could long continue to be viewed without jealousy by the native princes of India. Such of them, accordingly, as retained any sense of national honour, were naturally hostile to the British, and were well disposed to unite against them as the common enemies of Indian independence. In 1814 the war with the Nepaulese commenced, and in the outset the reverses sustained by the British in their attempts to penetrate into the hill country, strongly excited the hopes of the native princes. In the following year, the valour and military talents of Sir D. Ochterlory, brought that war to a brilliant close; and the bravery and discipline displayed by the troops in the course of the campaign, renewed among the Indian princes the former impression of their invincible superiority. Whatever might be their ulterior views, therefore, they were compelled for the present to temporize, and to soothe their conquerors by an outward show of humility and peace.

A more favourable opportunity, as they conceived, soon occurred for successful resistance to the British power. From the constant wars and commotions in which India had from time immemorial been involved, it happened that a great proportion of the native population were trained to habits of disorder and military licence. At the general settlement concluded in 1805, it was naturally supposed that these bands of adventurers, having no longer any scope for their predatory enterprises, would betake themselves to pacific pursuits, and would thus be gradually dissolved among the mass of the people. It happened otherwise. Those hordes of freebooters, known under the general denomination of Pindarees, im-

India.

proved both in strength and union, and Scindia and Holkar, in whose neighbourhood they were settled, if they did not openly abet them, made no active efforts for their suppression. The nature of their force may be shortly described. It consists of a species of light cavalry, which was formerly attached to the native armies, in the same manner, and for the same purpose, as the Cossacks are to the armies of Russia. Their horses were trained to long marches and hard fare, it being their object to plunder the country, and to elude pursuit by the celerity of their movements. They were generally armed with a bamboo spear, from 12 to 18 feet long; every fiftieth man carried a matchlock; about 100 out of every 1000 were well mounted; of the remaining 600, 400 were indifferently mounted, and the rest were slaves, attendants, and camp-followers, mounted on wild ponies, and keeping up with the corps as they best could. About the year 1814, these predatory bands comprised about 40,000 horse, who followed plunder as their mode of subsistence, and were indeed a more formidable species of gang-robbers; but, like other robbers and murderers on a great scale, they assumed all the form and pomp of military array. The strength and numbers of this disorderly mass were daily increasing by deserters from Holkar's irregular bands, and from the loose cavalry establishments of Scindia and others, where they were retained by no tie but that of present advantage, and where their pay was always in arrear. The central situation of the Pindarees, at an equal distance from the three presidencies, rendered their hostility still more formidable, and enforced on the British the necessity of maintaining an extensive line of defence, which was always, however, penetrated by those flying hordes, and the territories of our allies exposed, in consequence, to annual devastations. In 1808-9, and in 1812, they carried their incursions into the British territories, and returned loaded with spoil. The fame of these successful exploits recruited their bands, and enabled them to extend their ravages. In October 1815, a force of 8000 Pindarees crossed the Nerbuddah in a north-west direction, and, dividing into two parties, they penetrated to the Kishna, though they were watched, and one party was surprised by a body of infantry and cavalry, which did them, however, little damage. They were only deterred from crossing into the Madras presidency by the swollen state of the river, along the fertile and populous banks of which they took their course, plundering as they went along, and committing every kind of enormity. In their return along the line of the Godavery and the Warda, they passed the British positions, making good their retreat with an immense booty, and with utter impunity. A second expedition was soon planned, which, crossing the Nerbuddah, appeared on the western frontier of the district of Masulipatan, under the Madras presidency, on the 10th of March 1816. Next day they made a march of thirty-eight miles southward, plundering ninety-two vil-

lages, with every circumstance of unheard of cruelty, and, on the 12th, they marched thirty-eight miles, plundering fifty-four villages. By the 17th May they had nearly all recrossed the Nerbuddah, loaded with spoil, and with scarcely any loss. During the twelve days that they had remained within the Company's territories, it was ascertained that 182 persons had been put to a cruel death, 205 were found severely wounded, and 3603 had been put to different kinds of torture.*

It now became necessary to adopt efficient means for protecting the country against these destructive visitations. For this purpose, a defensive line of posts was extended along the Nerbuddah, and across the country for about 150 miles. This was, as usual, soon penetrated by the activity of the enemy, and various expeditions advanced southward for the purpose of plunder. By the singular activity of the different corps, and by a train also of fortunate accidents, almost all of these expeditions were intercepted, broken, and discomfited, so that very few of the plunderers made good their retreat. It was resolved, however, in the year 1817, to commence offensive operations—to attack the enemy in their native haunts, and either to exterminate them, or to drive them from the advantageous position which they occupied, in the very centre of India. The season of inaction was accordingly spent in making preparations for a great military effort; and, by the end of the rainy season of 1817, a numerous and well-appointed army was ready for the field. The plan of the campaign was, that the armies of the different presidencies should advance southward, and gradually converging to a common centre, hem in, on every side, the devoted territory of the freebooters.

But, while this plan was in progress, it was interrupted, and part of the troops engaged in executing it were suddenly recalled, by the unexpected hostility of the native powers. Bajee Rao, the Peshwa, or Prince of Poona, who had long been impatient of the British yoke, availed himself of this opportunity to make a fresh attempt at independence. With a view of more vigorously prosecuting the war against the Pindarees, all the troops had moved southward, with the exception of a brigade which had been left at Poona; and it was to overpower this small body of troops that the Peshwa's first efforts were directed. They were completely unsuccessful, however; he was repulsed at all points, by the steadiness of the Company's troops. This action took place on the 5th November. On the 13th, the British were joined by General Smith's division, which had advanced on the Godavery, on an understanding that, if he did not hear daily from the resident at Poona, he should countermarch to that place. It was resolved to attack the enemy's camp next day, but it was found deserted. General Smith immediately commenced an unremitting pursuit of the Peshwa, who was hunted from place to place by the different corps of the British army, until he at length deemed it prudent to surrender. He was deposed from

India

India. his throne—a residence in a particular city was fixed upon for him; and a pension of about £100,000 *per annum* assigned him for his support. His dominions were, of course, taken under the administration of the British.

The Rajah of Nagpoor, Appa Sahib, who was held in the same thralldom by the British, pursued a similar course, and with the same results. On the 26th November, at sunset, he attacked, with a great superiority of force, the brigade left at the residency, which was, in consequence, in great peril. A doubtful contest was maintained through the night, and next day the attack on the British was renewed with fresh vigour. Under every disadvantage, however, these attacks were finally repulsed, and the weak prince, Appa Sahib, taking flight, sent to ask forgiveness from his enemies. The conditions offered him were, that his territories should be placed at the mercy of the British government—that he should give up all his artillery, disband his troops, and come in person as a hostage into the British camp; on an understanding, however, that if he acceded to these terms, the former relations between him and the British would be restored; it being at the same time understood, that he should cede part of his territory, and that due provision should be made for a greater degree of internal control over his future movements. Being threatened with an immediate attack, he came to the British camp with a few attendants. His troops, however, as if to shame their pusillanimous prince, fought an unsuccessful battle for his right and independence; after which, the city of Nagpoor, with its fort, was surrendered to the conquerors, and this second war brought to a triumphant close. Appa Sahib, afterwards repenting of his spiritless conduct, began to plot new schemes; when he was arrested by the British resident, and detained in close confinement. He found means to escape in the summer of the following year, and making good his retreat to the hills, where, being joined by a band of irregular followers, he continued to give disturbance up to the late accounts.

It had been the professed intention of the Anglo-Indian government, according to its usual arbitrary mode of treating the native powers, to force the two independent chiefs, Scindia and Holkar, into an acquiescence with its views in regard to the Pindarees, and also the Patans, a species of infantry, better appointed, and more regularly disciplined, than the Pindarees, but associated together on the same unlawful principle of indiscriminate plunder. Scindia had been compelled to temporize, and finally to accede to the British propositions; Holkar, feeling strongly the disgrace of yielding to foreign threats, resolved to try the fortune of war. A battle took place on the 21st December, in which he was totally defeated, with the loss of his camp and all his artillery. He sought peace, which was granted him, but he was compelled to accept of British protection and alliance, which has always been accounted the last dishonour of an Indian prince.

The main object of the war, which was the destruction of the Pindarees, was not, in any material degree, impeded by those incidental contests. According to the plan proposed, the different divisions of the grand army proceeded southward, converging

as they advanced for the purpose of surrounding their haunts, and preventing their escape. They were driven out of the province of Malwa, retiring as the British advanced, but were at length so effectually hemmed in, that, in attempting to retreat, they were intercepted at all points, and the greater part of them destroyed. The remainder were so humbled by fatigue and misery, that they were glad to submit on any terms, and at length the three chief leaders surrendered on condition that their lives should be spared.

It will now be proper briefly to revert to the commercial character of the East India Company, and to inquire what has been the general result of its transactions, considered merely with a view to its *profit and loss*. So long as the attention of the Company was confined merely to trade, the annual dividend which, from the year 1708 to 1764, varied from 5 to 10 *per cent.* may be taken as a tolerably fair criterion of the profit gained. The acquisition, in 1765, of the sovereignty and revenues of Bengal give rise among the proprietors to the most extravagant anticipations of wealth, and, on the faith of these, the dividend, as already mentioned, was raised to 10 and afterwards to 12 *per cent.* These expectations proving fallacious, it was, in 1773, lowered to 6 *per cent.* It was afterwards raised to 8, and, in 1784, to 10 *per cent.* Since the acquisition of the sovereignty of Bengal, it was not so much from *trade* as from *revenue* that the Company's profits were expected to arise. It was by the remittance of a large surplus revenue from India, that the proprietors hoped to be enriched. These hopes, however, have never been fulfilled. A large and increasing revenue has been indeed collected; but it has been invariably followed by an increase of charge; and the debt in India, which began in 1760, has been gradually increased to the enormous sum of £5,577,791, its amount in April 1818.

The constant increase of the charge is a standing subject of complaint in the correspondence of the Directors with their servants in India, whom they frequently accuse of the grossest profusion and corruption, reproaching them with the enormous expense of their establishment, and urging them, in the most earnest manner, to retrenchments and economy; while the servants, on the other hand, always hold out the most positive promises of their faithful management, and of their statements of revenue to be regularly overruled by the increasing charges of the succeeding year.

When Lord Clive was sent out to India, in 1765, it was for the purpose of securing the Company's revenue from the profusion and mismanagement of corrupt servants, against whom the clamour in this country was loud and general. No amendment, however, took place, and the Directors continued their complaints. During the ten years' administration of Mr Hastings, which commenced in 1772 and ended in 1783, the Company were deeply involved in the wars and politics of India, the effect of which, on the finances, appears to have been to increase both the revenue and the charge, and in the same proportion to accumulate debt. In 1772 the revenue of Bengal, Bihar, and Orissa, amounted to £2,373,650, the charges to £1,705,79; produ-

India. cing a surplus of L.668,371. The India debt amounted to L.1,850,166. In 1785 the revenues of Bengal, Bahar, and Orissa, including the new revenue of Benares, amounted to L.5,315,197; the charges to L.4,312,519; thus producing a surplus of L.1,002,678; to counterbalance which, however, the debt in India was increased to L.10,464,955. With the management of their affairs in India, the Directors never seem to have been satisfied; for we find them about this period complaining that certain late revenue regulations were made, "rather with a view of creating lucrative posts for a certain description of men, than with any design either of increasing the revenue, or of promoting commerce." In the same strain we find them complaining in a letter to Lord Cornwallis of a disposition in their servants to "innovation and experiment, without urgent necessity, or apparent cause, new institutions, and almost instant deviations from them, multiplication of offices, and increase of salaries." These, they continue, "are always introduced with flattering schemes of increase to the revenue and diminution of expense, which has hardly, in any instance, been realized by the event." In consequence of this constant increase of expence, though the Company's revenues were increased, the surplus revenue was diminished. In the same letter, the Directors state, that it was one million less than in 1766, when the Bengal revenues were acquired.

In 1793 the revenues amounted to L.8,225,628; the expence to L.7,007,050, thus yielding a surplus of L.1,218,578; and the debt was reduced to L.7,971,665. This state of the Company's affairs became the subject of the most extravagant declamations both in Parliament and elsewhere. The old delusion of Indian wealth, nearly as absurd as the South Sea bubble, was successfully revived; annual remittances of treasure were confidently expected and confidently promised; and the expected surplus was most gravely appropriated by acts of Parliament to its appointed ends. Mr Dundas was the principal actor in this solemn farce, in which, being probably credulous himself, he imposed on the credulity of others, boasting that India would be a vast source of wealth to the Company, and to the nation. These predictions were soon falsified by the event. The surplus of Indian revenue, for the appropriation of which so many wise provisions were passed, soon vanished, and in 1797, a deficiency appeared which continued till 1810. The revenues had, in the meantime, increased from L.8,225,628, their amount, in 1797, to about 15½ millions sterling; but in place of any surplus being remitted from India to Europe, there appears a balance against India, from 1797 to 1807, to the amount of L.1,629,701; and it appears, that, during this period, there was sent from England to India, more than was received, a sum of L.5,691,689. This was the sum, therefore, which England lost during these ten years, by its connection with India. From another account also it appears that, from 1793 to 1816, England remitted of cash to India

L.8,824,067 more than was received. (See *East India Annual Accounts laid before Parliament*, p. 19.)¹ In 1811, the revenues began again to exceed the charges; and, in the three following years, there was a large surplus of nearly three millions Sterling in each year. In 1816, 1817, 1818, this surplus continued to be above two millions annually; and it is stated by Mr Prinsep, in his narrative of the last Indian war,² that there was actually accumulated in the different treasuries of the Company bullion to the amount of eight millions Sterling. Here, then, was an opportunity for making a great remittance to the Directors in Europe. But of this large accumulation of treasure they received not one shilling. The Indian government was involved in a series of new wars, in the carrying on of which not only was all this wealth expended, but an additional sum of about 4½ millions Sterling was borrowed; so that the Indian debt, which in 1814 amounted to about 29 millions Sterling, was raised to nearly L.34,775,792, its amount in April 1818. Mr Prinsep, however, in his interesting account of the administration of Marquis Hastings, still confidently holds out the hope of a surplus revenue; and he founds his expectations, 1st. On a reduction of expence, in consequence of the peace recently concluded; and 2dly, On a great increase of revenue from the late extension of the Company's territories. It remains to be seen how far these expectations will be fulfilled.

A general view of the Company's affairs, discloses similar results. In 1772, after the possession of the Bengal revenues should have produced its full effect, the Company was involved in such difficulties that, on an estimate for three months of the payments falling due, and of the funds for their discharge, there appeared a deficiency of above L.1,200,000. At this time the Company was assisted with a loan of L.400,000, and afterwards of L.200,000 from the bank, and with L.1,400,000 from government. In 1773, from a general account of the Company's affairs, it appeared that their effects and credits in England, set against their debts, produced an unfavourable balance of L.1,431,421, 19s. 8d. The same account of their effects and credits in India, set against their debts, produced a favourable balance of L.4,364,993, 10s. 10d. Deducting the one from the other, the remainder, consisting of their whole available property, amounts to L.2,920,568, 10s. 10d. which is all, therefore, that remained of their original capital, amounting to L.4,200,000. According to a general account of the concern in 1793, this favourable balance was reduced to L.1,956,866, less than in 1772 by L.973,702, and to this we have to add an additional million of capital subscribed in 1789, at 174 per cent., amounting to L.1,740,000; thus showing a deterioration of the Company's affairs, from 1772 to 1793, to the amount of L.2,713,702. In 1810, the same general account showed a balance against the Company of L.6,025,505; to which the Committee of the House of Commons, appointed at that time to inquire into their affairs, having added the capital stock received

¹ Mr Prinsep has not told us on what authority this statement rests.

India. in 1793 and 1794, and made several other adjustments, there appeared a balance against the Company of L.11,062,591, which they had no effects to discharge. In 1813, this unfavourable balance had increased to L.7,773,492; but in 1815, the Company's affairs were so far improved that it was reduced to L.2,611,311. Adding the capital received, amounting to L.7,780,000, the balance against the Company appears, at this period, to be L.10,391,511.

Although, at each successive renewal of the Company's charter, the mercantile part of the community have remonstrated against the continued monopoly of the Indian trade, it was not till the year 1814 that this trade was in any degree laid open to the merchants of this country. This was effected by the act passed in 1813, which, with the exception of the trade in tea, and the China trade, opened the general commerce of India to the merchants of this country, under certain limitations and restrictions. The Company was as tenacious as ever of their valued monopoly; they gave it up only when they found they could no longer retain it; and they still contrived to narrow, as much as possible, the freedom granted, by unfavourable restrictions. The trade with China, and the important trade in tea, was still continued under a strict monopoly: and, as a security against apprehended dangers to their dominion, from an unrestrained trade, it was provided, that no vessel engaged in the private trade to India should be under 350 tons burden; that no vessel should proceed to any place on the continent of Asia, between the Indus and Malacca, without a special licence from the Directors, regulated by the Board of Control, nor to any place not on the continent of India, within the same limits without a special licence. The effect of these restrictions is greatly unfavourable to the extension of the Indian trade; as they exclude the British merchant from the eastern coast of Africa, from the Red Sea, the Persian Gulf, all the numerous islands scattered in the Indian Ocean, and all other countries eastward of Malacca; with which the Americans and others, who are freed from these restrictions, carry on an extensive and lucrative trade. The rigid monopoly still held by the Company of the Chinese trade and the trade in tea, is severely felt by the British merchant; the effect of it being to exclude him from a most beneficial branch of commerce, engrossed, not by the Company, but by foreigners. The trade between China and Europe, in which tea, the great staple of the one, is exchanged for the manufactured products of the other, is chiefly carried on by the Americans, for whose benefit, therefore, and not for the benefit of the Company, the British adventurer is excluded from this trade. Such further relaxation of the Company's monopoly is, therefore, still anxiously sought for by the merchants of this country, as would allow them to enter into such branches of commerce as are at present entirely engrossed by foreign merchants; and these demands are so just and reasonable, that, on every principle, they ought to be conceded. It is doubtful, however, whether the Company will agree to

soften, in the smallest degree, the harsh provisions of their pernicious monopoly. India

Under all the restrictions imposed on it, however, and under all the difficulties incident to new undertakings, the private trade to India has increased to such a degree, that the shipping employed in it during the last six years has nearly tripled the amount of the tonnage in the service of the East India Company. The extent of the trade carried on in private vessels has also been gradually increasing, until it now regularly exceeds that of the Company, although the private merchant is still excluded from the trade to China, and from the tea trade. The value of the tea, exclusively imported into Great Britain by the Company, generally exceeds three millions Sterling. During the two years, 1818 and 1819, it amounted in each year to L.3,062,734, and to L.3,645,078. Still, however, with little more than L.200,000 for this article in the list of private imports, the value of the latter exceeded that of the Company's imports in 1818 by L.4,905,846, and in 1819 by L.595,115. The following account will show the progressive improvement of the private trade:—*

Years.	Value of Exports by the Company, ending January 5,	Free Trade, including Privilege Trade.	Value of Exports by the Company, ending January 5,	Free Trade, including Privilege Trade.
	L.	L.	L.	L.
1815,	1,732,719	870,177	7,227,067	4,061,892
1816,	1,752,300	1,454,728	7,154,130	5,769,459
1817,	1,539,130	1,868,390	7,855,312	5,703,912
1818,	1,313,490	2,708,024	7,361,802	5,097,748
1819,	1,250,061	3,052,741	5,192,804	7,098,650
1820,	1,358,520	1,650,1	5,792,405	6,297,519

This account proves sufficiently what an important advantage would be conferred on Great Britain by setting free the commerce of India from the restraints imposed on it. The use of British manufactures is daily becoming more common, and there is no doubt that if more scope and facilities were afforded to the free trade, it would soon become beneficial and lucrative. And when we consider the commercial embarrassments under which the country has been long labouring, it seems but reasonable that every possible expedient should be adopted for the revival of its depressed commerce, and that, if the grievance of the Company's unjust monopoly cannot be entirely done away, the mischief should still be confined within the narrowest limits possible.

The article *BENGAL*, in the *Encyclopædia*, contains an account of that province. The article *HINDOOS* contains an account of the manners, religion, arts, and learning of the people of India. The article *HINDOSTAN*, contains a geographical view of India, and narrates its earlier history; while the history of its more recent wars, and revolutions, down to the conclusion of the Mahratta war, under Marquis Wellesley, is given under the article *INDIA*. (c.)

* See Papers ordered to be printed by the House of Commons, 1819.

Ingenhousz. **INGENHOUSZ** (John), an eminent physician and natural philosopher, was born at Breda in 1730. He was first established in medical practice there, but removed to London in 1767, particularly with a view to study the improved methods of inoculation then lately introduced. Having become acquainted with Sir John Pringle, at that time President of the Royal Society, he was by him recommended to the Austrian ambassador, for the purpose of inoculating the Imperial family at Vienna, the Empress Maria Theresa having lost two of her children by the natural small-pox. He accepted this engagement in 1768, and having been perfectly successful in his operations, he was remunerated by the grant of a pension of £600 a year for life, together with the titles of Aulic Counsellor and Physician to the Imperial Family. He was also consulted, in his medical capacity, by many others of the most distinguished personages at Vienna, and he enjoyed the particular esteem of the Emperor Joseph II. who was fond of receiving him in his cabinet, and of witnessing the exhibition of a variety of physical experiments, with which it was always the delight of Ingenhousz to amuse and instruct his acquaintance of both sexes. The following spring he went to Italy, and inoculated the Grand Duke of Tuscany. He was made a Fellow of the Royal Society in May 1769; but he appears to have remained some years in Italy; for he was at Leghorn in January 1773; in March he dates from Salzburg; and in November 1775 from Vienna. The next year he was in London; and, in the winter of 1779, he went to Paris. The latter part of his life he spent principally in England, which, notwithstanding his dislike to the chilliness of the climate, was always his favourite residence, and "where he enjoyed during many years," to use his own words, "that felicity which a free and independent man finds in the pursuit of knowledge and wisdom, in the society and friendly intercourse of those who have distinguished themselves by their learning."

Dr Ingenhousz was cheerful in his disposition, and often playful in his conversation. Though his pursuits were chiefly scientific, he was not destitute of taste for literature and poetry. He had a particular predilection for Lucan, and for the Cardinal de Polignac, and would frequently recite passages from their poems with great energy, and with a strong German accent. Nor did he disdain the comforts of commercial opulence, and he was often a visitor at the magnificent villa of the late Mr Rucker of Rom Hampton. He had been introduced there by his friend Dr Brocklesby, who was in many respects of a perfectly congenial disposition, and who had great pleasure in prevailing on him to partake occasionally of his own hospitality, when his table would otherwise have been solitary. He died the 7th September 1799, at Bow Wood, in Wiltshire, the house of the Marquis of Lansdown, who had long known and esteemed him.

Dr Ingenhousz's principal publications are, 1. *Experiments on the Torpedo*. *Phil. Trans.* 1775, p. 1. Mr Walsh had lately gained considerable reputation by his account of the effects of the torpedo. These experiments, which were made off Leghorn, in com-

pany with Dr Drummond, are merely illustrative of the properties of that animal, which are now better known; and they afford no decided test of the electrical nature of the phenomena.

2. *Methods of Measuring the Bulk of Mixtures of Common Air, and Nitrous Air, with Experiments on Platina*, *Phil. Trans.* 1776, p. 257. The eudiometrical apparatus is described as an improvement on Fontana's. The experiments are intended to show that platina is not an alloy of iron and gold, since it may be deprived of all magnetic properties by repeated cupellation.

3. *A Way of Lighting a Candle by an Electrical Spark*. *Phil. Trans.* 1778, p. 1022. A very small charged jar setting fire to pulverised resin, strewed on cotton.

4. *On the Electrophorus*, p. 1027. This is a Bakerian lecture, read by appointment of the President and Council of the Royal Society, relating to the instrument then lately invented by Professor Volta, and which had been made known to the author by the Archduke Ferdinand. Its action is explained upon the elementary principles of the Franklinian theory. The next article in the volume contains some experiments of Mr Heuly in confirmation of the doctrines here advanced.

5. *On a New Inflammable Gas*. *Phil. Trans.* 1779, p. 576. A powerful explosion is produced by the detonation of the vapour of a single drop of ether with oxygen gas. The author takes occasion to investigate the elasticity of the gas evolved by the detonation of gunpowder; and agrees with Bernoulli in estimating it as equivalent to near 2500 atmospheres. It may here be remarked, that notwithstanding Bernoulli's general accuracy, and great mathematical talents, he has fallen into a very singular error, in comparing the force of gunpowder with the daily labour of men; and has accidentally made the force of one pound equivalent to the daily work of 100 men, while, in fact, the force of 40 pounds is only equivalent to the daily labour of a single man.

6. *On a mode of Suspending Magnetical Needles*, p. 537. Proposing that a hollow needle should be immersed in linseed oil, so as to press with a small portion of its weight only on its axis, in order that the friction may be greatly diminished.

7. *Improvements in Electricity*, p. 661. On plate machines of glass and pasteboard, and on a ribbon machine. A Bakerian lecture.

8. *Experiments on Vegetables*. 8. Lond. 1779. This volume is chiefly occupied by the detailed proofs of the author's principal discovery, that vegetables in general pour out a portion of oxygen gas in the sunshine, while they rather diminish its proportion at night and in the shade. It is dedicated to Sir John Pringle, and was translated into French by the author. 8. Paris, 1786. Second edition, 2 vols. 8vo. 1787-9. Latin by Scherer. Vienna, 1786. Dutch by Dr Van Breda, of Delft, with others of his works.

9. *On the Salubrity of the Air at Sea, and at Places far removed from the Sea*. *Phil. Trans.* 1780, p. 554. From the imperfection of the test employed, it was easy to imagine that some differences were discovered, which subsequent observations have shown to have no existence.

Ingenhousz 10. *Nouvelles Expériences et Observations*, 2 vols. 8vo. Paris. On different subjects of natural philosophy. In German by Molitor, *Vermischte Schriften*. Vienna, 1784.

11. *On the Influence of the Vegetable Kingdom in the Animal Creation*. *Phil. Trans.* 1782, p. 426. Asserting the accuracy of his experiments, and denying some statements of Dr Priestley; advancing, in particular, many arguments to prove that the air obtained is really supplied by the vegetables, and not by the water in which they are usually immersed, in order to collect it. Dr Ingenhousz was, on all occasions, anxious to support his claim to this very interesting discovery; and he insisted that Priestley's earlier experiments, on the green matter contained in stagnant water, had little or nothing in common with his own, because that matter was, in fact, of an animal nature. He was in the habit of collecting the

gas from cabbage leaves, and of keeping it bottled up in his pocket: and he was prepared with some coils of iron wire fastened into the corks, in order to exhibit the brilliant phenomenon of their combustion to his friends: the public being at that time less accustomed to this dazzling exhibition, than it has become in later years, when elementary lectures on chemistry have been more commonly addressed to mixed audiences than heretofore.

12. *Essay on the Food of Plants*, 8vo. Lond. 1798 From the French.

13. Dr Ingenhousz also inserted some essays in different volumes of the *Journal de Physique*; but they possess less originality and importance than his English publications.

(*Chalmers's Biographical Dictionary*, XIX. 8vo. Lond. 1815—*Keatseloot, in Biographie Universelle*, XXI. 8vo. Paris, 1818.) (U. N.)

I N S E C T A.

THE animals which Linnæus included in his class Insecta have been distributed into four classes by modern naturalists. These are termed, Crustacea, Myriapoda, Arachnides, and Insecta. The distinguishing character of these different groups have already been laid before our readers under the article ANNULOSA, in which the systematical divisions of the three first have been pretty fully illustrated. In regard to insects, a reference was there made to the present article. In the fulfilment of our plan, we shall now take a view of the structure and physiology of insects; their classification, and the methods of preserving them for the cabinet, which are now in use.

The attention of naturalists, in general, has been confined to an examination of the forms of insects and the number of their parts. Their internal structure has been in a great measure overlooked, and little accurate information is known concerning many of their functions. The task, indeed, of examining the anatomy of insects is one of peculiar difficulty. The organs, in many cases, are complicated in their structure, and limited in size, so that in dissecting them, the point of a needle must frequently be employed instead of a scalpel, and the eye requires the assistance of high magnifiers. There are few, therefore, who have prosecuted this department of the subject with zeal or success, and who have inspired others with confidence in the accuracy of their statements. Swammerdam and Lyonet, however, form illustrious exceptions.

In the observations which we propose to lay before our readers in this article, we will confine ourselves, in the first place, to a brief exposition of the anatomy and physiology of insects, as the statements are given in considerable detail in the *Encyclopædia*, under the article ENTOMOLOGY. It was necessary, however, to advert again to the same subject, for the purpose of noticing some of the recent discoveries which have been made by modern naturalists. In

the second part of the article, there will be given an abridged view of the modern method of classifying insects. In the illustration of the first part of the subject, we shall begin by considering,

I.—The Organs of Protection and Motion.

The skin of insects serves the double purpose of protection and support, and represents the cutaneous and osseous systems of the vertebral animals. Its structure appears much more simple than in the higher classes, as it can neither be said to possess a mucous or cellular web or true skin. It bears the nearest resemblance to the cuticle of the skin of the higher classes, or rather, all the laminæ of perfect skins are here incorporated into one uniform plate. It exhibits very remarkable varieties of texture. In some insects, as the house-fly, it is soft and pliable, while in others, as some of the weevils, it approaches the consistence of bone. In some species it is elastic, in others brittle.

The appendices of the skin consist of spines, hairs, and scales. The spines are merely projecting portions of its substance, and are usually distributed over certain parts of the feet, to aid the locomotive powers. Hairs are often distributed over the whole body; and, while they pass into spines on the one hand, they become, on the other, so exceedingly fine as to require the aid of a powerful magnifier to trace their character. These spines and hairs, being merely elongations of the skin, are not easily rubbed off. It is otherwise with scales. Some of these are inserted into their skin at their proximal, and are free at their distal extremity, and are so feebly connected, as to fall off, in many species, by touching them with the finger. These scales, in the butterfly, bear a remote resemblance to feathers in their form, and are very extensively used as pleasing objects for the microscope.

The MUSCLES of insects appear to possess the same internal structure as the same organs in the

Insecta.

higher classes. They are nearly all simple, and more or less transparent and whitish. All those which are concerned in the production of locomotion have their origin and insertion in the skin, apparently without the intervention of tendons. The different members appear to be connected with each other, by the intervention of a more transparent, tough substance, than the skin in other places, to which the name of ligament may be applied. The action of the muscles will be best understood by a description of the different parts of the body, and the motions which these perform.

1. The **HEAD** of insects contains the organs of the external senses and the mouth. It is joined to the trunk behind, and has its motions regulated by its mode of connection. Where the head is united to the trunk by a cylinder of ligament, the motion of which it is susceptible is various, limited chiefly in the dorsal direction by the superior margin of the trunk. When the articulation is effected by the immediate contact of the more solid surfaces, the three following modifications of joints present themselves. In the first, there are two or more rounded smooth tubercles, received into corresponding cavities in the trunk. The motion is consequently either backwards or forwards. In the second mode of articulation, the head is rounded posteriorly, and received into a socket in the thorax. In this manner great liberty of motion is obtained. In some cases, however, it is restrained by projections of the trunk, which limit it in one direction. In the third, the articulation takes place by the contact of two flat surfaces. The head is frequently contracted behind and the trunk in front, to diminish the uniting surfaces, but such joint admits but of very imperfect motion.

The muscles of the head take their rise near the abdominal edge of the trunk, and, entering the occipital hole, become attached to its margin. Those which move the head upwards take their rise on the upper part of the trunk; while those which depress it arise from the under side. These last are the largest. Those which arise from the lateral parts of the trunk, give to the head its lateral motions.

The characters derived from the head, which are used in classification, are chiefly taken from the markings of its surface, the inequalities of its margin, its size, and shape. They are, in general, obvious and permanent.

2. The **TRUNK**, as an organ of support to the other members, may be considered as the most important part of the body. The terms, however, which are employed to designate its different parts are neither appropriate nor well defined. Linnæus, in reference to this organ, gives the following enumeration of its parts: "Truncus, inter caput et abdomen, pedatus, thorace supra dorso, postice scutello, subtus pectore sternoque." By modern authors, it is usually divided into the thorax and breast.

The **Thorax** is the second ring of the body, and is united on the fore part with the head, and behind with the third ring or breast. In many species, this part is minute, while, in others, it occupies a large portion of the body. On its ventral aspect, it bears

the fore legs, or first pair, and between these is the *thoracic sternum*, frequently in the form of a keel, and terminating behind by a spinous process, which rests upon the pectoral sternum, as in the genera *Elatér* and *Dytiscus*. It may be considered as the only fixed part of the body, giving origin to the muscles of the head, the fore legs, and frequently, also, to the breast and abdomen.

The characters furnished by the thorax are extensively employed in the arrangement of insects. These are chiefly taken from its appearance on the back of the animal.

The **Breast** is frequently so much incorporated with the thorax, as to appear as one organ. In other cases, it seems to form a part of the abdomen. In the back, it frequently exhibits a horny process, termed *scutellum*, analogous in consistence to the thorax, to which it is united behind. At this place of the breast, the wings have their origin. On its ventral side, it supports the middle and hind legs. Between these, at the base, is the *pectoral sternum*, which, in some species, expands into a cover for the first joint of the hind legs, and in others is produced to cover a portion of the abdomen. The breast contains the muscles for moving the middle and hind legs, the wings and abdomen; and it likewise contains some very strong muscles, passing from its ventral to its dorsal surface, and calculated to bring these, when required, nearer together. This motion is probably facilitated by the number of sutures with which its skin is traversed. The characters for classification are chiefly taken from the scutellum and sternum.

3. The **ABDOMEN** is the last portion of the body of insects. In some species, it is sessile, and intimately united with the breast; in others it is divided by a stalk. It consists of rings, varying in number in different genera. These rings are joined together in many species by a simple adhesion of the margin, while, in others, the posterior margin of the one includes the anterior margin of the other. The motion of the whole abdomen takes place by means of muscles, which arise in the breast, and, in those where it is sessile, the motion is very limited. The rings themselves are likewise susceptible of a little motion, especially when they are included. The muscular fibres which change their position are longitudinal, and pass from the posterior margin of one joint to the anterior of the other, and are able to draw the ring to one side, or pull it within the one which immediately precedes it.

The classical characters derived from the abdomen are chiefly taken from the number of the rings, their connection, and the condition of their surface. At the termination of the abdomen, the anus and external orifice of generation are situated. These have frequently appendices, which we will afterwards notice.

4. The **MEMBERS** of insects are of two kinds, wings and feet.

The wings vary in their number, structure, and appendices. In one class, they are wanting, and hence termed *Apterous*; in another they are two in number, but the greater number have four. These wings are either membranaceous, and supported by

Insecta.

Insecta. corneous ribs, which form a net-work in their substance; or, where the wings are four in number, the upper pair are sometimes crustaceous, obtain the name of *elytra*, and serve as a covering to the inferior ones. The ribs of the wings, improperly denominated nerves, in the manner of their distribution, the hairs by which they are covered, and the form of the vacant spaces, exhibit great regularity in the individuals of the same species. The manner in which the membranaceous wings are folded up, when at rest, is various. In some they are folded longitudinally, in others transversely, and in others obliquely. Each of these arrangements prevail throughout extensive groups. In the *Diptera* there is, under or behind each wing, a stalk terminating in a small knob. These are termed *halteres*, or *poizers*, and are considered as the rudiments of the second pair of wings. Between each poizer and the base of the wing, one or two spoon-like scales are found, termed winglets. They have likewise been observed in a coleopterous insect, *Dytiscus marginalis*. In some of the *diptera* they are absent. The use of these appendices of the wings has not been satisfactorily determined. The muscles which move the wings take their rise in the breast, and are capable of executing their functions with great celerity. The *elytra* perform no other motion than elevation and depression, and serve merely to protect the wings when at rest, not to assist them when flying.

The characters employed in the classification of the primary divisions of insects are, in a great measure, derived from the wings. Their presence or absence—their number and appendices—their texture and consistence, together with their size, position, and manner of folding up, yield marks which are of easy detection, and which experience has found to be permanent.

The legs of true insects are six in number. The first pair take their rise under the thorax, and the second and third pairs under the breast. They consist of the five following parts, the hip (*coxa*), the thigh (*femur*), the leg (*tibia*), the toe (*tarsus*), and the claw (*unguis*).

The hip, or *coxa*, serves to unite the limb with the body. It is usually short, or nearly as broad as it is long. It is imbedded in the thorax, or breast, and is limited in its motion by the mode of insertion. Sometimes its proximal extremity is globular, and received into a corresponding cavity of the body, giving to it a very extensive degree of motion. In other cases, the *coxæ* of the hind legs are consolidated with the breast.

The thigh, or *femur*, is usually united with the *coxa*, in such a manner as only to admit of motion backwards and forwards. At its coxal extremity, the *femur* has, in some tribes, one or two eminences, in some cases produced into spines, which are termed *trochanters*, and as they are hollow within, they are considered as furnishing suitable insertions to the muscles for particular motions. When the thigh is slender and cylindrical, the motion of the legs is confined to walking, but where leaping is required, or even swimming, the thigh is thick, and bellied, to give room to the requisite muscles.

The leg, or *tibia*, is articulated to the *femur* in such a manner as to admit of motion only in the same plane in which it moves. In those insects which swim, this joint is long and flattened, while, in those which dig holes in the ground, it is strong and serrated on the margin.

The toe, or *tarsus*, consists of several joints, which are articulated more loosely than the preceding parts of the limb, and admit not only of motion outwards and inwards, but likewise in a lateral direction. Its strongest muscle, as in the other parts of the leg, is the flexor. It is only by means of this part that the feet can apply closely to any object. The joints vary in number, length, and size; and, in many species, are furnished with very singular appendices. Those which deserve particular notice are denominated cushions and suckers, and are situated on the under surface of the joints. Accurate representations of these remarkable organs are given by Sir Everard Home, in the *Philosophical Transactions for the Year 1816*, (Plates XVIII.–XXI.), from the beautiful drawings of Mr. Bauer.

The claw (*unguis*) is attached to the distal edge of the last joint of the *tarsus*. In a few species it is single, or capable of being opposed to a projection, serving the purpose of a thumb. In others, the claws are double, and either move in the same plane, or act in opposition. The muscles of the different parts are all included in the limb, except those of the *coxæ*, which originate in the trunk. The former gives origin to those of the *tibia*, the latter to the first joint of the *tarsus*, and this again to the one which succeeds. These muscles are chiefly fixators and extensors, the former placed on the ventral, the latter on the dorsal surface of the limb.

From the enumeration which has now been given of the different organs calculated for the production of motion, we may see that insects are qualified for executing different kinds. Some, indeed, can only walk, others can walk and leap. Some can only walk and fly, others can walk, fly, and leap, while many can walk, fly, and swim, and, in addition, a few of these can leap.

II.—The Organs of Sensation.

The nervous system, in the class of animals now under consideration, exhibits a greater uniformity of structure and disposition than any of the other great systems of organs which they possess. The brain is situated in the head, on the dorsal surface of the gullet. It consists of two lobes, which exhibit slight variations of form, and are frequently so intimately united, that they appear as one, marked, however, in the middle by a groove. These lobes furnish the optic nerves, and frequently send filaments to the mouth. Near the posterior edge, two cords arise, which, after proceeding backwards, and, in many cases, embracing the gullet, unite to form a ganglion, from which nervous filaments proceed to the neighbouring parts. From this ganglion, two cords again proceed and form a second ganglion, and the same process is repeated until the cords reach the anal extremity, where they terminate. The number of ganglia which are formed, differ in different

Insecta.

genera, according to the number of articulations of the body. The cords, in some species, appear to unite and exhibit only the appearance of one.

The organs of the senses are more imperfectly developed in the insects than in the crustacea. The eye alone is the most perfect of any of these; and next to it may be classed the organ of touch. The existence of the other senses common to the vertebral animals, is rather inferred from the actions performed than from the structure of their parts.

It would lead into too extensive details were we to give an account of the various instincts which insects exhibit, the knowledge which they possess of external objects, and the indications of memory and reasoning which their actions indicate. Many of these have been already communicated under the articles ANT and BEE, and to the reader who is desirous of more information on the subject, we would recommend *An Introduction to Entomology*, by Messrs. Kirby and Spence; two volumes of which have already appeared (1821), and the sequel is anxiously expected.

III.—Organs of Nutrition.

Under this division of our subject we include the alimentary canal, with all its appendices,—the vessels employed in circulation,—and those which are destined for aerating the blood.

1. ALIMENTARY CANAL. In treating of this important organ of nutrition in insects, it is necessary to begin with a description of the parts employed in obtaining and preparing food for the gullet. In many cases, as in the higher orders of animals, the legs, particularly the first pair, execute the first movement of seizing the food and conveying it to the mouth; in general, however, the parts of the mouth, unassisted, seize, cut, bruise, and prepare, the food for the gullet.

1. The *masticating* organs include the four following parts (which we shall designate by their Latin appellations, for want of appropriate English terms), labrum, mandibulæ, maxillæ, and labium. These form the mouth, and are denominated *Instrumenta cibaria*.

The *labrum* is analogous to the upper lip of the higher classes of animals. It is articulated to the fore part of the head (*frons*, or *clypeus*, *chaperon* of the French), either directly by a simple suture, or by the intervention of a plate, to which Kirby, from its situation, has given the name *nasus*. The labrum itself, at its free edge, exhibits great variety of character in the condition of its margin, of which entomologists have availed themselves in the discrimination of species. This organ may be regarded as the cover to the other parts of the mouth above.

The *mandibulæ* are two in number. They take their rise immediately below the labrum on each side. They exhibit very remarkable differences, in size, shape, and armature. They move horizontally, and serve to cut objects by their edges crossing like the blades of scissors.

The *maxillæ* are likewise two in number. They are united to the cheeks immediately underneath the mandibulæ, and between these organs and the labium. They are more complicated than the mandibulæ.

On their inner margin they are usually covered with stiff hairs. Externally they support the *palpi*, which are articulated appendages, consisting of two or more joints. Each maxilla is furnished with one of these, rarely with two. The use of the palpi has not been determined, although it is probable that they serve as organs of smell, and perhaps also of touch.

The *labium* is analogous to the under lip, and closes the under side of the mouth, resting on the maxillæ. Its free edge is variously marked, and there is usually a line in the middle, indicating its tendency to be double. On each side it supports a palpus consisting of two or three joints. Its base is connected laterally by ligament, with the base of the maxillæ, and behind with a fixed plate jointed to the head, and termed *mentum*, corresponding, in position, with the nasus of the labrum.

When all these parts bear such a proportion to one another as to be able to cut the substances on which the insects feed, and convey them to the pharynx, they are considered as in the most perfect condition. But all these parts in the different classes exhibit very remarkable modifications. There are many species, which are destined to live chiefly or exclusively on fluid substances, to whom such masticating organs would be unsuitable. Those which hold a middle station between the gnawers and suckers, have the labium transformed into a soft fleshy plate like the tongue of quadrupeds (and hence frequently termed *lingua*), capable of licking, and of being rolled inwards when at rest,—as in the Hymenoptera, represented by the bee. In the genuine suckers, the organs of the mouth present two important modifications. In the first, the labrum is nearly obliterated; the labium is produced and either crustaceous (rostrum), or membranaceous (proboscis), with a groove on its upper side, for the reception of the four plates or hairs into which the two mandibulæ and maxillæ have been converted. These appearances are exhibited in the classes Hymenoptera and Diptera. In the second, both the labrum and mandibles are nearly obliterated, and the labium is short and fixed; and the two maxillæ are produced and so applied to each other as to form a sucker. This sucker is capable of being rolled up spirally, and as it appears in the Lepidoptera, the butterfly for example, is usually termed the proboscis or tongue.

All these different parts of the mouth, however much they may be modified in size and shape, may still be readily detected, either by their position or palpal appendages. We owe this discovery of the true nature of the parts of the mouth of insects and the other pedate annulosa to M. Savigny, who has accompanied his judicious observations with accurate representations of each organ, and its various changes in the *Mémoires sur les Animaux sans Vertèbres*, premier partie, Paris, 1816.

* 2. The orifice of the *gullet* is, in general, a simple aperture into which the food is conveyed chiefly by the agency of the maxillæ. In some cases, however, chiefly among the Hymenoptera, there is an organ on the base of the mouth, more or less distinct, to which the term *lingua* ought to be restricted. M. Savigny calls it *glossa* or *hypopharynx*. On the

Insecta.

Insecta dorsal margin of the opening there is likewise, in some cases, a particular process, which is denominated by the above naturalist *epiglossa*, or *epipharynx*.

The gullet itself is usually membranaceous, and is either simple or furnished with an enlargement, denominated the first stomach. In the true stomach the walls present the appearance of muscular fibres, and in some of the Orthoptera these bands cover the whole surface, forming a true gizzard, fortified with teeth or scales pointing backwards. The intestines are variously convoluted, and frequently, after the anus, exhibit an enlargement which has been denominated a rectum. In some cases the canal is furnished with one or more side pouches, or *cæcæ*, near the stomach.

The hepatic vessels (for there is no secreting organ which can be compared to a liver) have their origin in the fluid contents of the abdomen, and even send their capillary extremities to the remotest parts. They vary greatly in number and size. The walls are dense and cellular, and the bile which they secrete is yellow, brown, or white, according to the species. These vessels, in some, terminate separately, in others they unite into a common duct. The terminations vary greatly, being in different species at the pyloric extremity of the stomach, the middle of the intestine, or at the rectum.

In insects, neither absorbing nor circulating vessels have been detected, although anxiously looked for by many celebrated anatomists and microscopical observers. The nutritious portion of the food appears to be absorbed by the walls of the intestines, and discharged into the cavity of the body, where there are neither veins, arteries, nor heart. Towards the back, indeed, there is an obvious vessel, placed longitudinally, to which some have given the name of heart, but which is more generally denominated the *Dorsal Vessel*. This vessel is widest in the middle, and diminishes in size at each extremity. Its walls consist of two membranes, the internal one muscular, and the external one cellular. This last is so much crowded with tracheal vessels, as to appear to be entirely composed of them. All the coats are liberally provided with nervous filaments. This vessel is kept in its position by the tracheal tubes, and by muscular fibres, which, in general, are disposed in triangles, and increase in breadth from the superior part of the body to its inferior extremity.

The contents of the dorsal vessel are fluid, but of such consistence, that, when its coats are punctured, no liquid flows out. The colour is usually similar to the adipose matter which is collected on or near its surface, and differs according to the species. When placed under a microscope, this humour appears to consist of grains or globules, containing other globules. It mixes readily with water, and when dried, resembles gum.

The humour of the dorsal vessel is subject to

Insecta some degree of motion, arising from the contractions which it experiences. These are irregular as to time, and proceed from the one extremity to the other, by stages usually corresponding with the rings of the animal, and strongest in the abdomen. The nerves do not appear to exercise any influence on these contractions. The muscular fibres and tracheal filaments appear to exercise the greatest control. These contractions, which in some species are little more than thirty in a minute, in others amount to one hundred and forty in number, according to the species, have been denominated pulsations, and the organ itself has been termed a heart. To that viscus, however, it bears no resemblance, except in its contractions, which are, however, irregular. It neither receives nor gives motion to any circulating fluid. Its use appears to be, to imbibe and convert the fluid of the abdomen into fat, to serve as a supply in those numerous cases where much nourishment is suddenly required, as during the metamorphoses of youth, and the production of eggs in maturity. The peritoneal membrane appears destined to execute the same functions.*

If there is thus no heart, and no circulation of the nutritive fluid obtained from the food, in what manner is this fluid aerated? In reference to this subject, Cuvier justly observes, "le sang ne pouvant aller chercher l'air, c'est l'air qui va chercher le sang." (*Léons*, IV. 165.) The object is accomplished by a very complicated apparatus. On each side of the body are small orifices, termed *stigmata*, differing in number according to the species. These are formed by a cartilaginous ring, and in some cases furnished with one or more valves. Each orifice is the extremity of a short tube, which opens internally into a cavity, one on each side of the body, and extending from the head to the tail. From these lateral cavities arise innumerable tubes, termed *tracheæ*, most numerous at the termination of the stigmata, which convey the air to every part of the body. To enable them to do this, their coats consist of an external and internal cellular membrane, with a middle layer, consisting of a cartilaginous string, spirally twisted, resembling the spiral tubes of plants. These tracheæ, by their number and subdivisions, convey air to every part of the body, and form, indeed, the great bulk of its contents. In what manner the vitiated air is expelled, has not been ascertained in a satisfactory manner.

From this view of the nutritive system in insects, it appears that the chyle is absorbed by the inner surface of the alimentary canal; that it exudes from its external surface into the common cavity, that the tracheæ aerate this mass; and that, while the dorsal vessel and the peritoneal membrane prepare fat, the hepatic filaments separate from it bile, and probably urine. The existence of this last excrementitious fluid is evinced by the presence of urea in the excrement.

* See "Observations on the Use of the Dorsal Vessel," by M. Marcel de Serres, translated in *Annals of Philosophy*, IV. p. 346; V. p. 191, 369, and VI. p. 34.

IV.—Organs of Reproduction.

Insects have the sexual organs on different individuals, impregnation takes place internally by their union, and the females are all oviparous.

In the male, the sexual organs bear a closer resemblance to those of the mammalia than some of the higher classes. The *testes* may be regarded as two in number, situated one on each side of the abdomen. In some cases they appear a simple mass, while in others they are subdivided into a number of lobes, which may be regarded as so many separate organs. The *spermatic* ducts are two in number, varying greatly in length and the number of tubes, which, like roots, combine in their formation. They unite into a common duct near the penis; but, previous to doing this they are joined by the ducts of the vesiculæ seminales, and other accessory tubes, which, in different genera, exhibit a great diversity of character. The penis is usually a simple tube, in some cases protected at the base by two scales, which separate upon entering the vagina of the female, and thus prepare a passage for the penis, and serve likewise for retention. The external opening is usually situated at the extremity of the abdomen, beside the anus. In the libellulæ or dragon-flies, it is seated at the base of the abdomen.

The males of insects are seldom of so large a size as the females, and frequently exhibit peculiar characters in their abdomen, eyes, or antennæ, by which they may be distinguished.

The female organs exhibit fewer varieties of structure in the different genera than those of the other sex. The ovaria consist of numerous tubes, in which the eggs are prepared. These open into a common oviduct, terminating in the vulva. Previous to the termination of the oviduct, it receives the ducts of one or more vesicles. To the sagacity of John Hunter we owe our knowledge of the use of these: "In dissecting," says he, "the female parts in the silk moth, I discovered a bag lying on what may be called the vagina, or common oviduct, whose mouth or opening was external, but it had a canal of communication between it and the common oviduct. In dissecting these parts before copulation, I found this bag empty; and when I dissected them after, I found it full." (*Phil. Trans.* 1792, p. 186.) By the most decisive experiments, such as covering the ova of the unimpregnated moth, after exclusion, with the liquor taken from this bag in those which had sexual intercourse, and rendering them fertile, he demonstrated that this bag was a reservoir for the spermatic fluid, to impregnate the eggs as they were ready for exclusion, and that coition and impregnation were not simultaneous. It has not been determined, whether the same arrangement prevails in all insects. This is a very near approach to the external impregnation of the ova, as takes place in many fishes and reptiles.

The female insect may, in general, be distinguished from the male, by the superior size of the abdomen. In some cases, both males and females survive the process of generation, to repeat it again in another season. In other cases, the female only sur-

vives, while, in many, death ensues, upon the eggs being prepared and excluded. Insecta.

The apparatus with which some insects are furnished, to enable them to place their egg in a proper situation, has been denominated the *ovipositor*. It is a continuation of the vulva, more or less strengthened by bony spiculæ, according to the nature of the substance it is destined to penetrate.

The period which elapses between the union of the sexes, and the laying of the eggs, extends to days in some, and even to months in others. The eggs themselves are either deposited at once, or at particular intervals. They are deposited under one or other of the following conditions. In the first, the egg, upon being deposited, is left to the influences of external circumstances, and the young, when hatched, to the resources of their own instinct. In the deposition of the egg, the wisest arrangements are made for the welfare of the young. The mother attaches them, in general, to those substances on which, upon being hatched, they are destined to feed. The butterfly attaches her eggs to a leaf; the flesh-fly deposits her's upon carrion; while others insert them into the young of other insects. Not a few females prepare a particular hole, in which they place the egg, and lay up for the young a suitable provision when they burst the shell. In the second, where the insects live in society, the eggs are deposited within the dwelling, and the young are reared and fed by the mother's care, or rather by barren females which act as slaves.

In the aphides, or *plant lice*, as they are called, the female retains the eggs at one time until they are hatched, and at another lays them like other insects. There is another circumstance no less remarkable in these insects,—one act of impregnation not only renders fertile the eggs of the individual, but the young produced from these eggs, and from the eggs of those, even until the ninth generation.

When the eggs are hatched, the young are termed grubs, maggots, caterpillars, or, technically, *larvæ*. In this state they are proverbially voracious, and their digestive organs are of much greater dimensions than when arrived at maturity. In the condition of larvæ insects possess a variety of members, as legs, suckers, hairs, and even stigmata, which they do not possess in their maturity. They are all, however, destitute of wings. Some of them live constantly in the water, instead of the land, their future residence,—swimming in youth, and flying in maturity. The food of the larvæ is often solid, requiring powerful jaws to gnaw it, while the food of the perfect insect is fluid, and sucked up. When the larva has attained a certain size, and acquired the requisite quantity of fat, having been nourished either by the food which it has acquired by its own industry, as the caterpillars, or by that which has been brought to its cell, as in the grub of the bee, it prepares to assume the forms of maturity, by passing through the third stage of existence as a *pupa*. In this state, the parts, which were suitable only in the larva condition, either become obliterated, or are changed into organs fit for maturity. The following conditions of the pupa state are recognised by naturalists:

Insecta.

1. Some insects of the apterous tribes, merely by repeated castings of the skin, arrive at the perfect state without undergoing any sudden or remarkable change of form or structure. These are termed *Pupæ completæ*. They move and eat like the perfect insect.

2. Many insects, which have wings in the perfect state, are observed to obtain first the rudiments of them, and afterwards all their parts, and to assume the form of the perfect insect while passing through this period of youth, without any particular transformation. In this state they are called *Pupæ semi-completæ*. Like the *pupæ completæ*, they likewise move and eat like the perfect insect. In the different kinds of pupæ which remain to be considered, the animal neither eats nor moves. It derives its nourishment from its stores of fat.

3. After retiring to some suitable place, the larvæ of some insects cast their skin, and disclose the body of an ovate form, enveloped with a coriaceous covering, forming within separate sheaths for the different external organs. In this covering all the changes of form and structure take place, which prepare it for maturity. These are termed *Pupæ incomplete*.

4. Other insects, likewise, upon changing their skin for the last time in their larva state, appear within a coriaceous covering, destitute, however, of any sheaths within for the external organs; these last being closely applied to the body. These are termed *Pupæ oblectæ*.

5. In the last form of the pupa, the skin, instead of casting, is changed into the coriaceous covering. Such are termed *Pupæ coarctatæ*.

All insects, which do not eat, and are motionless in the pupa state, are careful to retire to situations, sufficiently remote from enemies, of suitable temperature and moisture. In many cases, the larva forms an exterior covering, in which the pupa may be lodged with greater safety. This covering is in some composed of threads of the well known substance termed silk. Sometimes only one or two threads are required to keep the pupa in a proper position; in others, the silk is woven into cloth, or so matted together, as to resemble paper. These external cases are termed cocoons. The matter of which they are fabricated is prepared by two long tubes, which take their rise in the abdomen, enlarge as they approach the head, and terminate by a duct, which opens under the labium. By pressing the orifice of this duct to one place, and then to another, the larva draws out the tenacious threads.

The larvæ that live in cells ready fabricated for their reception, as the wasp and the bee, are not contented with these as a covering during the pupa state, but they line their sides and bottom, and cover their mouth with silk, thus making a complete cocoon. These, after the insect has been perfected, are left in the cell, and when it contains another larva, a second lining is likewise prepared. Each lining at the bottom, in the case of the bee, covers the excrement, which the animal had produced in its larva state. Hence, the walls of bee-combs appear double or treble; nay, John Hunter, by whom the appearance was observed, has counted twenty different linings in one cell. (*Phil. Trans.* 1792, p. 198.)

Insecta.

The external covering of the pupa, in some cases, consists of pieces of earth or dried leaves, curiously joined together, and cemented by an adhesive secretion.

After the insect has remained in a pupa state for a certain period, exceedingly different in the various tribes, it bursts forth from its confinement in its state of maturity. In this perfect condition it is termed the *Imago*. The organs of reproduction now speedily enlarge, and preparation is made to increase and multiply.

We now come to the second object proposed in this article, the modern method of classifying insects. The arrangement of insects has occupied the attention of many acute and accomplished naturalists. As yet, however, a considerable difference of opinion prevails, as to the characters which should be employed in the formation of the orders and other subordinate divisions.

Since the days of Swammerdam, there have not been wanting naturalists who have regarded the metamorphoses of insects as furnishing the most suitable characters for primary divisions. But, instead of adopting the four forms of metamorphoses of that author, they have divided insects into such as do not undergo changes of form in the third or pupa state, and such as do undergo changes.

Linnaeus, to whom zoology in all its branches was greatly indebted, gave to insects a uniformity of nomenclature, and a methodical arrangement, greatly superior to all his predecessors. His primary divisions were taken from circumstances connected with the condition of the wings. The simplicity of this method, and the obviousness of the characters which have been employed, have obtained for this system a decided preference among the entomologists of Britain. Perhaps the strongest objection which can be urged against this method is its limited nature, arising from the great increase of species, and the consequent influx of new characters calling for the formation of additional divisions.

Fabricius introduced a method of classifying insects, founded on the organs of the mouth, which has met with many admirers. These *instrumenta cibaria* furnish permanent and definite characters, and exhibit, in the modifications which they present, marks well calculated for fixing the limits of species and genera. They are, however, in many cases minute: careful dissection is requisite for their display; and not unfrequently the aid of the microscope is necessary.

All the organs which compose the animal frame have certain mutual relations, so that any remarkable modification in the structure or functions of one set of organs is usually accompanied with corresponding changes in the other systems. Thus in the case of insects, when we observe any remarkable modifications taking place in the masticating organs, we observe equally remarkable variations in the locomotive organs, as these two systems of organs are correlative. Hence it happens that the divisions of the Linnean classification are frequently co-ordinate with those employed by Fabricius.

These considerations have induced modern ento-

and of Linnaeus, and so and so of Amsterdam. The characters employed by Linnaeus occupy the first rank, because they are most apposite to the species. Those of Fabricius are reserved to the cases where the locomotive organs do not furnish marks sufficiently characteristic.

In the following brief description of the modern state of Insectology, it is not, perhaps, the most necessary to recount what has been formerly said. It would indeed be a tedious task to detail the characters of the genera, which would to add an enumeration of the species. We therefore regret this constraint, and the characters of the Linnean genera, and many of the species, with notices of their habits, have been preserved in the latter in the *Encyclopædie*, under the article *Entomologie*. In Plates XXIV. and XXV. of the *Supplément*, there have been given examples of some species in all the classes.

CLASS I.

COLEOPTERA.

The insects of this class have their arguments of a coriaceous consistence, approaching, in some genera, to the hardness of shell. The wings are four in number. The upper pair, denominated elytra, are of the same texture with the skin. They are convex above, concave below, and, when at rest, their medial margins meet by a straight suture. In some genera, the elytra are completely united at their anterior ends; and, in others, they meet at the base of the suture, and are in contact, or separate, each other, while at the extremity they recede from each other. The inferior pair of wings are membranaceous, strengthened by arborescent ribs, and when at rest they are folded obliquely and transversely, and concealed under the elytra. When the insect is about to fly, the elytra are raised, and remain fixed while the under wings unfold and execute their motions. In some species, the under wings are imperfectly developed, or nearly obliterated, and consequently flying is impracticable. In such cases the elytra are cemented at the anterior ends, and the posterior consists of six or seven rings, which are united to the elytra, each of which have two small spines on each side. The antennæ exhibit a great variety of character in their situation, length, form, and number of the joints. The eyes are compound and two in number. Each eye, however, is divided by the continuity of the marginal band of the head. There are no ocelli. The instrumental organs are formed for cutting and masticating solid substances. The food, however, which is consumed by them differs greatly, according to the species, in kind and consistence, so that all the parts of the digestive system exhibit extensive modifications of form. They are all oviparous. The larva is elongated, frequently destitute of antennæ and eyes, or with a few or sixteen rings, with a scaly head, and the mouth of the mouth similar to the perfect insect. It is usually six feet. After continuing months, or even years, in the larva state, it changes into a pupa, through the skin of which the different members may be distinctly perceived. The

perfect state require a supply of food; and they are greater in number than other insects. They are very numerous in species and genera. Linnaeus has divided this extensive order into three groups, according to the antennæ were filiform, filiform, or lamellate. M. Geoffroy employed the number of joints of the tarsus as the basis of his subdivisions. This method, though it separates a very few naturally connected genera, and is liable to some exceptions, is nevertheless so simple and easy of application, that it has been universally received throughout Europe.

1. COLEOPTERA PENTAMERA.—Under this head are included those species which have five joints in each antenna. The genera which they form are distributed by Lamarck into three sections, according as the antennæ are filiform, including those which are moniliform, or beaded, clavate or lamellate. (*Hist. Nat. des Animaux sans Vertèbres*, Tom. IV. p. 439.) Latreille, whose industry and acuteness have contributed greatly to extend the limits of entomology, has subdivided them in the following manner. (*Regne Animal*, par M. Cuvier, III. p. 473.)

1. COLEOPTERA CARNIVORA.—The distinguishing character of the insects here referred to, and one which is peculiar to them, is the possession of six palpi, in place of four, the ordinary number, two of these attached to the labium, and two to each maxilla. The maxillæ are hooked, and covered on the inside with stiff hairs or spines. They have two stomachs. The first is short and muscular, the second more produced, with villous walls. The hepatic vessels are four in number, and terminate at the pylorus. The antennæ are filiform or setaceous. The thighs of the middle and hind legs, furnished with large trochanters. They are carnivorous both in their larva and perfect state. In the former the body consists of three rings, the head and the first ring scaly, with two or three antennæ.

1. Carnivora Terrestria.—The feet are formed for walking. The mandibulæ are apparent, the body is oblong, and the eyes prominent. The intestine terminates in a large cloaca, with two vesicles secreting a fetid humour.

1. CARABIDÆ. The maxillæ are furnished with an articulated claw. Mandibulæ prominent, straight, and denticulated; eyes large and full; labium short, the tibia of the fore legs destitute of a notch on the inner side. In the genera *Manticora*, *Cicindela*, *Megacephala* and *Therates*, the breadth and the length of the thorax are nearly equal, and all the joints of the tarsus are entire. In the genus *Collyris* of Fabricius, changed by Latreille into *Collyris*, the thorax is narrow, and produced, and the penultimate joint of the tarsus is bilobed.

2. CARABIDÆ. The maxillæ destitute of the articulated claw. In general, the head is narrower than the thorax, and the mandibulæ are destitute of teeth. This very numerous family has been divided by Latreille into seven sections.

1. The external maxillary and labial palpi, with the last joint equal or larger than the preceding. The tibia of the fore legs have a deep notch on the inner side; elytra truncated or obtuse; labium entire and oval, or nearly square; the head's contract-

Insecta. ed behind; and, with the thorax, is narrower than the abdomen; the thorax is heart-shaped and truncated behind, and its length never exceeds, but frequently falls short of its breadth. This section includes the following genera: Anthia, Graphipterus, Brachinus and Lebia. This last genus has been subdivided into the following genera by Bonelli, viz. Hellus, Cymindus, Lamprias, Dromius, and Demetrias.

2. The genera of this section exhibit the same form of palpi and elytra. The head is deeply divided from the thorax, to which it is joined by a socket; the labium is furnished on each side with a lobe; the thorax is lengthened; the penultimate joint of the tarsi frequently bilobate. The genera are, Zephium, Galerita, Drypta, Agra, and Odacantha.

3. The palpi and tibiae present the same characters as the preceding. The elytra are not truncated; the suture of the mentum is obsolete. This includes the genus Siagona.

4. The genera of this section differ from the preceding ones, in the tibiae being denticulated externally. The second and third joints of the antennae are nearly equal and moniliform; the elytra are entire, and the mentum articulated. This includes the genera Searites and Chivina.

5. The elytra are entire; the mentum articulated; anterior tibiae entire externally, with short terminal spines; labium pointed in the middle, with lateral lobes. This section contains the genera Ozena, Morio, Aristus, Harpalus, Feronia, Licinus, Badister, Panagaeus.

6. The elytra are entire, and the anterior tibiae very slightly, or not at all notched; labium pointed. This includes Cycchus, Pamborus, Calosoma, Carabus, Nebria, Omophron, Pogonophorus, Loricera, and Elaphrus.

7. In this last section, two at least of the exterior palpi are pointed at the extremity. The anterior tibiae are notched. Bembidion, Trechus, and Apollonius.

II. Carnivora Aquatica. The feet of the insects here referred to are formed for swimming. The mid and hind legs are compressed or ciliated; the mandibles are concealed; the terminal hook of the maxilla bent from the base; the thorax is broad; they live in the water both in the larva and imago state. The larvae are long and narrow, with twelve rings; the head large, with strong hooked mandibulae, pierced at the apex. The body has six feet.

1. **DYTICIDÆ.** The antennae are filiform, and longer than the head. In the males of many species, the three first joints of the tarsi of the mid and fore legs are dilated, and furnished with complicated suckers. In a few genera, the tarsi of the mid and fore legs have only four joints, as Hyphydrus and Hydroporus; in the others, the tarsi are entire, as Haliphus, Pelobius, Noterus, Laccophilus, Colymbetes, Hydaticus, Acilius, and Dytiscus.

2. **Gyrinidæ.** The antennae are here clavate, with a subsidiary ciliated one at the base of each, each eye divided into two by the marginal band of the head. There is only one genus belonging to this family, Gyrinus.

II. PENTAMERA MICROPTERA.—The insects of

Insecta. this division constituted the genus Staphylinus in the Linnean system. They are characterized by their filiform or moniform antennae, sometimes thickening a little towards the end. The body is narrow, and the elytra scarcely reach to half the length of the abdomen. The coxae of the fore and mid legs are remarkably large. Two bags are protruded at pleasure from the anus. They run and fly readily. When pursued, they elevate their head and abdomen, and assume a very threatening attitude. They frequent moist places, in the neighbourhood of putrid animal or vegetable substances. A few are found in flowers, in pursuit of minute insects. Their first stomach is very short, and without folds; the second is long and villous, with a short intestine. The species are very numerous, and have been divided into many genera, which admit of the following distribution:

1. Head exposed, and separated from the thorax by an obvious mark. Among these there are some which have the labrum deeply divided into two lobes. The **STAPHYLINIDÆ** are distinguished by their filiform palpi, and consist of the following genera: Staphylinus, Pinophilus, and Lathrobium. The **OXYPORIDÆ** have the four palpi, or at least the labial ones, terminated by an enlarged joint, as in Oxyporus and Astraphaeus. In other genera, the labrum is entire. In the **PÆDERIDÆ**, the maxillary palpi are nearly the length of the head, as in Pæderus, Evæsthetus, and Stenus. In the **OXYTELIDÆ**, the maxillary palpi are greatly shorter than the head, and the antennae are inserted in front of the eye, as in Oxytelus, Siagonium, Omalium, Piestes, Proteinus and Lesteva. The **ALEOCHARIDÆ** differ from the preceding family in the antennae being inserted between the eyes, as in Aleochara.

2. Head sunk in the thorax as far as the eyes. In the **LOMECHUSIDÆ**, the tibiae are entire, as in Lomechusa. In **TACHINIDÆ**, the tibiae are spinous, as in Tachinus and Tachyporus.

III. PENTAMERA SERRICORNIA.—The elytra cover the abdomen; the antennae are usually filiform, or slightly clavate; and, in the males particularly, serrated, pectinated, or plumose. In some of the genera, the thoracic sternum is advanced in front, under the head, and likewise produced behind. This character is exhibited in those which have the mandibles notched or bifid at their extremity, as the **ELATERIDÆ**, a numerous family, in which the natural genera have not yet been established; and, in those which have entire mandibles, as **BURRESTIDÆ**, having filiform palpi, and containing the genera Buprestis, Tracys, and Aphanisticus; and the **MELASIDÆ**, in which the palpi have an enlarged terminal joint, as Melasis and Cerophytum.

In those whose thoracic sternum is destitute of the singular character exhibited by the preceding families, there are several genera in which the mandibles are forked at the apex, or furnished with a tooth beneath. In some the body and elytra are soft. In these the head is furnished with a neck in **LYMOXYLONIDÆ**, in which the elytra do not embrace the abdomen, as Lymoxylon, Hylecatus, Atractocerus, and Cupes; and, in **MASTIGIDÆ**, in which the abdomen is embraced by the elytra, as in Mastigus and Scydmanus. In others, the neck is concealed, as in

Insecta **MELACHRUSIDÆ**, which exhibit, as a peculiar character, four vesicles divided into lobes, under the thorax and the base of the abdomen, which can be withdrawn or exerted and inflated at pleasure. The **MELYRIDÆ** have the palpi filiform, as *Melyris* *Dasytes*, and *Drilus*; while in **CLERUSIDÆ**, the palpi are securiform as *Clerus*, *Tillus*, and *Enoplium*.

In those families where the body and elytra are firm and crustaceous, the **PTINUSIDÆ** have the head and thorax narrower than the abdomen, with the antennæ about the length of the body, as *Ptinus* and *Gibbium*; and the **ANOBIDÆ**, having the thorax of the size of the abdomen, and the antennæ much shorter than the body, as *Anobium*, *Ptilenus*, and *Dorcatoma*.

There are several genera which agree with some of the preceding in the softness of their bodies, but whose mandibles are entire at the apex. In some of these the palpi are filiform, as in the **CEBRIONIDÆ**, which have tarsal joints entire, as *Cebrio* and *Hammonia*; and in **SCIRTESIDÆ**, which have the penultimate joint of the tarsus bifid, as *Scirtes*, *Elodes*, *Rhipicera*, and *Dascillus*. In others, the palpi, especially the maxillary ones, become thicker towards the extremities. In the **LAMPYRIDÆ** the antennæ are approximate at the base, and the maxillary are longer than the labial palpi, as in *Lampyrus*, *Lycus*, and *Omalisus*. In the **TELEPHORIDÆ**, the antennæ at the base are remote, and the labial and maxillary palpi are nearly of equal length, as in *Telephorus* and *Malthinus*.

IV. PENTAMERA CLAVICORNUA.—The antennæ are here obviously club-shaped, perfoliated or solid, generally exposed at the base, and longer than the maxillary palpi. In a few genera, forming the family **DRYOPSIDÆ**, the first and second joints of the antennæ are enlarged, and the remainder form a club nearly solid, so that they appear three jointed; as *Dryops*, *Hydera*, and *Heterocerus*. In the remaining families, the antennæ increase more gradually from the base, and the club consists of several joints. In some of these the pectoral sternum is produced under the head towards the mouth. In the **HISTERIDÆ**, the mandibles are prominent, and the antennæ geniculated, as *Hister*, *Abrarus*, *Orthophilus*, *Dendrophilus*, and *Platysoma*. In the **BYRRHIDÆ**, the antennæ are straight, as *Byrrhus*, *Thaliscus*, *Anthrenus*, *Chelonarium*, *Nosodendron*, *Elmis*, *Macronychus*, *Georissus*, and *Megatoma*. In other genera, the pectoral sternum is abbreviated in the usual form, as the **DERMESTIDÆ**, which have the mandibles short, thick, and straight, at the extremity, as *Dermestes* and *Attagenus*. In the remaining families, the mandibles are lengthened, compressed, and hooked, at their extremity. The **NITIDULIDÆ**, the mandibles are notched, bifid, or furnished with a tooth at their extremity, as *Nitidula*, *Biturus*, *Cateretes*, *Micropapilus*, *Thymalus*, *Colobicus*, *Engis*, *Ips*, *Scaphidium*, *Scaphisoma*, and *Choleva*. The **SILPHIDÆ** have the extremities of the mandibles entire, as *Silpha* and *Necrophorus*. The insects of this family are reputed to feed on carrion, and to dig under dead mice and moles, and bury them in order to feast upon them more securely. These statements are without foundation. They feed on maggots, and their pupæ, and, in penetrating the ground in search of

Insecta the last of these, they loosen the soil so much, that the dead animal sinks under, by its own weight, or, if light, is elevated on a hillock.

V. PENTAMERA PALPICORNUA.—The maxillary palpi nearly equal, or surpass the elevated antennæ in length. These last are inserted in a pit beneath an unusual production of the anterior margin of the head. In the **HYDROPHILIDÆ**, the first joint of the tarsus is abbreviated, and the legs are flattened, and formed for swimming, as *Hydrophilus*, *Spercheus*, *Elophorus*, and *Hydrana*. In the **SPHERIDIADÆ**, the five joints of the tarsus are distinct, as in *Spherdium* and *Cereyon*.

VI. PENTAMERA LAMELLICORNUA.—The insects of this division are readily recognized by their club-shaped antennæ, the extremity of which is divided into laminae, capable of receding or approaching at pleasure. The **LUCANIDÆ** differ from all the rest of this tribe in the laminae of the club of the antennæ being placed (not as in the other families, approximating at the base, and opening and shutting like the leaves of a book, but) like the teeth of a comb perpendicular to the axis, as *Lucanus*, *Smოდendron*, *Isalus*, *Lamprina*, *Platyceres*, and *Passalus*. In the **COPRIDÆ**, the membranaceous termination of the maxilla is large and transverse; the antennæ have eight or nine joints; the labrum is concealed by the semicircular margin of the head; the mandibles are soft; and the last joint of the labial palpi comparatively small, as *Copris*, *Alenchus*, and *Aphodius*. The **GEOTRUPIDÆ** have the terminal joint of the labial palpi as large as the preceding one; the antennæ have eleven joints, and the mandibles are horny as *Geotrupes*, *Lethrus*, and *Typharus*. In the **SCARABEIDÆ** the antennæ have nine joints. The labium is concealed by the mentum, as *Scarabeus*, *Trox*, *Egialia*, *Oryctes*, *Hexodon*, and *Rutella*. The **MELOLONTIDÆ** have the mandibles greatly concealed by the head and the maxilla, as *Melolontha* and *Anoplognathus*. In the **GLAPHYRIDÆ** the labium is advanced and divided into three lobes, as *Glaphyrus*, *Amphicoma*, and *Anisonix*. The **TRICHIADÆ** have membranaceous mandibles, as *Trichius*, *Golethius*, *Cetonia*, and *Crematoscelalus*.

II. COLEOPTERA HETEROMERA.—The insects belonging to this great subdivision have the tarsi of the fore and mid legs furnished with five joints, as in the preceding, but the tarsi of the hind legs have only four joints. In a few genera, as *Rhinomacer*, *Rhinosimus*, and *Stenostoma*, constituting the family **RHINOMACERIDÆ**, the front of the head is advanced into a snout, on which are seated the antennæ. In the remaining genera, the front exhibits the usual characters. In some, the head is triangular, or heart-shaped, and is furnished with a neck, and the maxillæ have no corneous tooth on their inner edge. Among these, there are some which have the claws simple, as the **PYROCHROIDÆ**, with bilobate tarsi, including the genera *Pyrochroa*, *Notoxus*, *Scaptia*, and *Dendrocerus*. In the **MORDELLIDÆ**, in which the tarsi of the hind legs at least are simple, are included the *Mordella*, *Rhipiphorus*, *Anapsis*, *Horea*, and *Apalus*. Among others, the claws are double, or deeply divided. In the genus *Tetraonix*, the penultimate joint of the tarsi is bilobate in the others entire. In the **MYLABRIDÆ**, the an-

Insecta. tennæ are thickened at the extremity, as in *Mylabris*, *Hycleus*, *Cerocoma*, while in the *CANTHARIDÆ*, the antennæ are of equal thickness throughout, or rather taper towards the point, as *Cantharis*, *Meloe*, *Zonites*, and *Onas*.

Among those genera which have the head oval and destitute of a neck, there are some which have the maxillæ furnished with a corneous tooth on the inner side. The elytra in some are free, and cover membranaceous wings, as the *TENEBRIONIDÆ*, including *Tenebrio*, *Opatrum*, *Crypticus*, *Sarotrium*, and *Toxicum*. In many other genera, the elytra are united, and the membranaceous wings are nearly obliterated. Some of these have the maxillary palpi filiform, with the last joint nearly cylindrical. The *EUODIUSIDÆ* have the maxillæ covered with the mentum, as *Erodium* and *Pimelia*. In the *SCURTIDÆ*, the base of the jaws are exposed, as *Scaurus*, *Fargelia*, *Sepidium*, *Moluris*, *Tentyria*, *Hegester*, *Eurychora*, and *Akis*. Others have the extremity of the maxillary palpi enlarged, or securiform. In the *ASIDIDÆ*, the base of the maxillæ is concealed by a large mentum, as *Asida* and *Chiroseelis*. In the *BLASPIDÆ*, the base of the maxillæ is exposed, as in *Blaps*, *Misolampus*, and *Pedinus*.

The genera, in which the maxillæ are destitute of a corneous tooth on the inner side, are likewise numerous. Many of them have the antennæ cylindrical, or slightly tapering. The *MELANDRIADÆ* have the penultimate joint of the tarsi bilobate, as *Melandria*, *Lagria*, *Culpea*, *Nothus*, *Odemera*, *Stenostoma*, and *Rynomacer*. In the *HELOPSIDÆ*, the joints of the tarsi, at least those of the hind legs, are entire, as *Helops*, *Seropalpus*, *Hallomenus*, *Pytho*, *Nitidus*, and *Cistela*. Others have the antennæ more or less club-shaped, and generally perfoliate. The *HELEADÆ*, including the genera *Helea* and *Cossyphus*, have the head concealed, or received into a notch in the front of the thorax. The remaining families have the head exposed and projecting. In the *DIAPERIDÆ*, the insertion of the antennæ is concealed by the lateral margin of the head, as in *Diaperis*, *Hypophleus*, *Trachyseelis*, *Eledona*, *Cnodalon*, and *Eptagus*. In the *LEIODESIDÆ*, the insertion of the antennæ is exposed, as in *Leiodes*, *Tetratoma*, *Lustrophus*, and *Orchesia*.

III. COLEOPTERA TRIMERA.—The tarsal joints of all the feet are four in number. They are phytivorous, and live chiefly in wood or on flowers. In one extensive group, the head is produced in front, in the form of a snout. Among these there are two genera, *Brechus* and *Anthribus*, in which the snout is short, and the labrum and palpi distinct. In the remaining genera the snout is long, and the labrum and palpi obscure. In the *CIRCULIONIDÆ*, including the genera *Circulio*, *Rhynchænus*, *Gionus*, *Calandra*, and *Rhina*, the antennæ are distinctly geniculated. The *Brentusidæ* have antennæ destitute of the knee, as *Brentus*, *Orchestes*, *Rhamphus*, *Brachycerus*, *Cylas*, *Apoderus*, *Attelabus*, and *Apion*. In another group, equally numerous, the forehead is of the usual size. Among these, there are some which have eleven joints in the antennæ, and the third joint of the tarsi bilobate. The antennæ, in some, terminate in a perfoliate club, as the *EROTYLUSIDÆ*, including *Erotylus*, *Triplax*,

Lanugria, and *Phalacrus*. In others, the antennæ are filiform. In the *CERAMBICIDÆ*, the labium is dilated and heart-shaped at the extremity, including the genera *Cerambyx*, *Prionus*, *Callidium*, *Necydalis*, *Saperda*, *Iamia*, *Stenocorus*, *Leptura*, together with *Spondylis* and *Parandra*. In the *CHRYSOMELINIDÆ*, the antennæ are shorter than in the preceding family, and the labium is plain. It includes the following genera, *Chrysomela*, *Cassida*, *Cryptocephalus*, *Clythra*, *Galeruca*, *Altica*, *Hispa*, *Crioceris*, *Donacia*, and *Sagra*.

In those which have not eleven joints in the antennæ, and the third tarsal joints bilobate at the same time, there are some which have the third tarsal joints entire. The *MYCETOPHAGIDÆ* have eleven joints in the antennæ, as *Mycetophagus*, *Uleiota*, *Cucujus*, *Agathidium*, *Zylophila*, *Meryx*, and *Trogossita*. In the *BOSTRICHIDÆ*, the joints of the antennæ do not exceed ten, as *Bostrichus*, *Cerylon*, *Nemosoma*, *Cis*, *Cerapterus*, and *Pausus*. The *SCOLYRUSIDÆ* have the penultimate tarsal joint bilobate, as *Scolytus* and *Phloeotribus*.

IV. COLEOPTERA TRIMERA.—The tarsi in this division are all three-jointed. The antennæ are clavate. In the *COCCINELLIDÆ*, the antennæ are shorter than the thorax, as *Coccinella* and *Chilocorus*. In the *ENDOMYCHIDÆ*, the antennæ are longer than the thorax, as in *Endomychus*, *Lycoperdina*, *Dascarus*, and *Eumorphus*.

V. COLEOPTERA DIMERA.—The tarsal joints are only three in number. The genera hitherto determined amount only to two, as *Claviger* and *Pselaphus*. The latter, however, has been recently constituted into a family, *PSELAPHIDÆ*, including *Pselaphus*, *Euplectus*, *Bythenus*, *Acropagus*, *Tychus*, and *Bryaxis*.

CLASS II.

STREPSIPTERA.

This class was instituted by Mr Kirby, one of the most acute and intelligent observers among the British entomologists. The elytra (if such they can be called) are coriaceous, and arise, not from the upper side of the breast, but from the base of the coxæ of the anterior pair of legs, consequently they are remote from each other. They first recede from the body, then approach, and lastly recede again, exhibiting a tortuous course. They do not cover the wings. These last are firmly membranaceous, and their ribs are simple, diverging from the base, and folding longitudinally like a fan. The parts of the mouth are obscure, apparently consisting of two minute two-jointed palpi and two maxillæ, thus intimating that the imago consumes but little food, and is short lived. The antennæ arise, each of them from a common jointed base, and afterwards divide. The eyes are pedunculated, two in number, and compound, with elevated septa, dividing the hexagonal lens; the terminal segment of the abdomen ends in a reflected process. The larva inhabits bymenopterous insects, in which it changes into a pupa coarctata with the head exerted.

This order contains only two genera, *Stylops* and *Zenos*. In the former, the upper branches of the antennæ are jointed, in the latter they are simple. The *Stylops melitta* and *tenuicornis* are natives of Britain.

INSECTA.

Since the institution of this class, doubts have been entertained as to the propriety of denominating the twisted processes which arise from the sides of the thorax, elytra. Latreille and Lamarck, without indicating much reluctance to increase the synonyms of the science, or delicacy towards the naturalist who first instituted the class, have suppressed the term Strepsiptera, the former substituting that of Rhipitera, the latter, with more classical propriety, Rhupidoptera (from *ῥηπις*), in reference to the fan-shaped wings.

CLASS III.

DERMAPTERA.

In this class, the elytra are short, coriaceous, with a straight suture. The wings are membranaceous, with longitudinal ribs, connected in the margin by a transverse one; they are folded when at rest longitudinally and transversely. The mandibles are bidentate. The maxilla have a scaly cylindrical appendix or galea. There are no pyloric cæca. The tarsal joints are three in number. The metamorphosis is semicomplete. This class comprehends the following genera: Forficula, Labia, and Labidura.

CLASS IV.

ORTHOPTERA.

The elytra, in the insects of this class, are coriaceous, and at their inner margin overlap each other. The under wings are membranaceous, and have numerous longitudinal ribs crossed alternately at right angles by an infinity of transverse ones, so that their reticulations, or little squares, are usually arranged like bricks in a wall; when at rest these are folded longitudinally, and unfold like a fan. The parts of the mouth are similar to the coleoptera, with the addition of the galea protecting the maxilla at the sides. The alimentary canal is furnished with a membranaceous crop, and a muscular stomach, armed with corneous scales. The pyloric cæca receive the biliary vessels, and a few likewise terminate in the intestine. The larvæ exhibit a pupa semicomplete. In all the stages of existence they live on the land.

Among the Orthoptera, there are several genera with their wings, when at rest, roof-like. These have either the tarsi with four joints, as the *LOCUSTIDÆ*, or the tarsi have only three joints, as the *ACHETIDÆ*, including the genera *Acheta*, *Truxalis*, *Ziphicera*, *Acrydium*, and *Pneumora*.

In the remaining genera, the wings are horizontal. Among these the *GRYLLIDÆ*, including *Gryllus*, *Tridactylus*, and *Gryllotalpa*, have the body not flattened, nor the sides truncated, but the abdomen is furnished with appendages. In the genus *Blatta*, the body is depressed, and the sides truncated, with abdominal appendages. The remaining genera, with horizontal wings, are destitute of abdominal appendages. These are the *MANTIDÆ*, including *Mantes*, *Empusa*, *Phasma*, and *Spectrum*.

CLASS V.

HEMIPTERA.

The insects of this class exhibit considerable differences with regard to their wings. In some, the

upper wings are true elytra, crustaceous, or coriaceous, with membranaceous extremities overlapping each other; while, in others, the upper wings are wholly membranaceous. In some of the genera, the males only are winged, or they are all apterous. They agree, however, in the characters exhibited by the parts of the mouth. These are formed for sucking. The labium is produced, with a canal on its upper surface, and consists of several joints. The mandibule and maxilla appear like four hairs, which, by their union, form the haustellum. The labrum is more or less produced as a covering to the base of these organs. The palpi are nearly obliterated. The metamorphosis is here semicomplete. This class is divided into two orders, which, in the opinion of some naturalists, ought to be elevated to the rank of classes.

I. *HEMIPTERA HETEROPTERA*.—These have the elytra crustaceous at the base, and the extremities folding over each other, and membranaceous. The rostrum is attached to the front of the head. The first segment of the thorax larger than the second, ocelli, two. The Heteroptera admit of subdivision into the terrestrial and aquatic.

The terrestrial heteroptera have two ocelli, the antennæ exposed, longer than the head, and inserted between the eyes near the inner margin. Some of these have the labium of four joints, and the labrum long, subulate, and striated above. Among these the *PENTATOMIDÆ* have five-jointed antennæ, as *Pentatoma*, *Cydnois*, *Tetyra*, and *Elia*. The *COCCIDIDÆ* have only four joints in the antennæ, as *Coccus*, *Berytus*, *Lygæus*, *Capsus*, *Miris*, and *Mydocha*. In another group the labium consists of only three joints, sheathing the labrum, which is short. In the *REDUVIIDÆ*, the rostrum is curved, as *Reduvius* and *Plocaria*; while in *CIMICIDÆ* it is straight, as *Cimex*, *Tingis*, *Aradus*, and *Phymata*. In a third group the labium consists of two or three joints, and does not embrace the labrum, as the *ACANTHIDIDÆ*, including *Acanthia* and *Galgulus*.

The aquatic heteroptera live in or upon the water. They are destitute of ocelli. In the *HYDROMETRIDÆ*, including *Hydrometra*, *Velia*, and *Geris*, the antennæ are long, and inserted between the eyes. In the remaining families, the antennæ are short, and inserted under the eyes, and are shorter than the head. In the *NEPADÆ*, the tarsi of the fore-legs are indistinct, as *Naucoris*, *Nepa*, and *Ranatra*. In the *NOTONECTIDÆ*, the anterior tarsi are distinct, as in *Notonecta*, *Plea*, *Sigara*, and *Corixa*.

II. *HEMIPTERA HOMOPTERA*.—In the insects of this division, the rostrum seems to originate from the chin. The second segment of the thorax is as long as the first. There are two or three ocelli. The *CICADIDÆ* have three joints in the tarsi, the antennæ consist of six joints, and there are three ocelli, as *Cicada*. The *FULGORIDÆ* have three tarsal joints and only three joints to the antennæ, and two ocelli as *Fulgora*, *Pleta*, *Issus*, *Tettigometra*, and *Delphax*. The *CERCOPIDÆ* differ from the preceding in the antennæ being inserted between the eyes, as *Cercopis*, *Étalion*, *Ledra*, *Membracis*, and *Tettigonia*. The *APHISIDÆ* have two joints in the tarsi, as *Aphis*, *Psylla*, *Thrips*, and *Aleyrodes*. The *COCCIDIDÆ* can boast of only one tarsal joint, as *Coccus*.

CLASS VI. TRICHOPTERA.

The wings of the trichopterous insects are four in number, and membranaceous. The upper ones are usually of a darker colour and firmer consistence than the lower ones. The ribs, which are usually hairy, are disposed longitudinally, and when they do anastomose, the intervening spaces are lengthened. The lower wings fold longitudinally. The mouth has a distinct labrum; the maxillary palpi have five joints. The labial palpi have only three joints, the last of which is a little enlarged. The maxillæ and labium are united, but do not form a sucker. There are two large compound eyes, and two ocelli. The legs are spinous, and the tarsal joints five in number. The larvæ live in the water in tubular dwellings, which they construct and move about with, open at both ends, and consisting of bits of stick, sand, or shells. Hence, they are usually called *case worms*. They change into a pupa incompletely in the tube, which they inhabited when larvæ, and when ready for exclusion, by means of the sheathed antennæ, and fore and mid legs, crawl out of the water, throw off the covering, and become inhabitants of the land.

Dr Leach has subdivided this class into two families. The *LEPTOCERIDÆ* have the antennæ much longer than the whole body, as *Leptocernis* and *Odontocernis*. The *PHYCOPHYLLIDÆ* have the antennæ only the length of the body, as *Mygane*, and *Limnephilus*.

CLASS VII. LEPIDOPTERA.

This extensive and beautiful class consists of the butterflies and moths. The wings are four in number, membranaceous in texture, irregularly ribbed, and covered with coloured scales, in the form of a lamaceous powder. The parts of the mouth are formed for suction. There are only vestiges of the labrum and mandibule. The maxillæ are produced, with a groove on the inner edge. When united, as they are naturally, they form a tubular proboscis, through which the animal obtains its food. The maxillary palpi are inserted upon the base externally, and are minute. The labium is short and without joints, and supports two obvious palpi with three joints. There are two compound eyes, and in some species two ocelli. The antennæ consist of many joints, and are usually much longer than the head. The segments of the thorax are united. The tarsal joints are six in number. The larvæ have six feet with claws, and from four to ten others on the posterior portion of the body, which they use as suckers. They are changed into a pupa obteeta. The genera are now divided into three orders, corresponding with the Linnean genera *Papilio*, *Sphinx*, and *Phalaena*.

I. *LEPIDOPTERA DIURNA*.—The upper wings, at least, in all the species are vertical in a state of rest, and the lower ones are destitute of hooks. The antennæ are clavated, or filiform, with hooked extremities. Among these, the *PAPILIONIDÆ* have the hinder tibiae furnished with two spines, situated at the tarsal end, as in *Papilio*, *Parnassius*, *Thais*,

Pieris, *Polyomatus*, *Heliconius*, *Danaus*, *Cethosia*, *Libythea*, and *Nymphalis*. The *HESPERIIDÆ*, including *Hesperia* and *Urania*, have four spines to the hinder tibiae, two in the middle and two at the tarsal extremity, as in the remaining *lepidoptera*.

II. *LEPIDOPTERA CREPUSCULARIA*.—The wings are horizontal in repose, and the under ones are furnished with a spine under the base, at the external margin which enters a hook on the lower side of the upper wings, as in the following division. The antennæ are prismatic and fusiform. The *GLAUCOPIDÆ* have the antennæ bipectinated in the male at least, as *Glaucopis*, *Stygia*, and *Procris*. The antennæ, in the remaining genera, are simple in both sexes. The *ZYGXIDÆ* have the palpi slender and hairy, as *Zygena*, *Sesia*, and *Macroglossum*. The *SPHINXIDÆ* have large scaly palpi, as *Sphinx*, *Smerthus*, and *Castinea*.

III. *LEPIDOPTERA TURNA*.—The insects included under this division have setaceous antennæ, diminishing in thickness from the base to the point. Among these, there are several families, in which the wings, when at rest, fold round the body. The *PTEROPHORIDÆ* have the margins of two of the wings, at least, divided into processes at each rib, as *Pterophorus* and *Orneodes*. The other families of the division have the four wings entire. The *TINEIDÆ* have only two palpi apparent, as *Tinea*, *Yponomeuta*, *Oecophora*, *Lathrosia*, and *Adela*. In the *ALUCIDÆ*, there are four palpi apparent, as *Alucita*, *Crambus*, and *Galleria*. Other families have the wings at rest, lying upon the body without inclosing it, and by their union form a lengthened triangle. The *AGLOSSIDÆ* have four apparent palpi, as *Aglossa* and *Botys*. The *PARALIDÆ* have only two apparent palpi, as *Pyrallis*, *Hermenia*, and *Platypteryx*. In the third division, the wings do not rest upon the body so as to form a triangle. The extensive family includes the following genera, *Phalaena*, *Campaea*, *Noctua*, *Cylamophila*, *Bombyx*, *Phalaena*, *Hepialis*, and *Cossus*.

M. Savigny has observed, that, in those cases where the maxillary palpi have only two joints, the proboscis is naked or pubescent, and when they consist of three joints, the proboscis is always scaly.

CLASS VIII. NEUROPTERA.

The wings in this class are generally four in number, wholly membranaceous, transparent, and greatly reticulated by the anastomosing ribs. The under wings are either larger or longer than the upper ones. The labrum, mandibule, maxillæ, and labium, are of the ordinary size, and formed for cutting. There are two large eyes, and two or three ocelli. The segments of the thorax are united, support the six legs, and are distinct from the abdomen.

In some of the families, the antennæ are about the length of the head, subulate, and consist of from three to seven joints, the last of which is setaceous. Among these the *LIBELLULIDÆ*, including *Libellula*, *Aeshna*, and *Agria*, have three tarsal joints, the mandibule and maxillæ corneous, and the terminal ring of the abdomen, furnished with hooks or scales. In the *EPHEMERIDÆ*, the mandibles are obscure,

Insecta. the tarsal joints four in number, and the terminal ring of the abdomen furnished with setæ, as in *Ephemera*, *Baetis*, and *Cloeon*.

In other families, the antennæ are much longer than the head, and consist of sixteen joints and upwards. Among these the *PANORPADÆ*, including *Panorpa*, *Nemoptera*, *Bittaces*, and *Boreus*, have the front produced into a snout. The remaining families have the front short. In the *MYRMELIONEDÆ* the antennæ are clavate, and the palpi six in number, as *Myrmelion* and *Ascalapus*. The two remaining families have filiform antennæ. The *TERMESIDÆ* have from two to three tarsal joints, as *Termes* and *Psocus*. The *HEMERORADÆ* have four or five tarsal joints, as *Hemerobius*, *Raphidia*, *Mantispa*, *Scalis*, *Corydalis*, *Chauliodes*, and *Osmylus*. The *PERLADÆ*, including *Perla* and *Nemoura*, have the inferior wings folded longitudinally.

CLASS IX.

HYMENOPTERA.

The wings are four in number, membranaceous, and divided into large unequal meshes by the anastomosing ribs. The under wings are the smallest. The organs of the mouth are adapted both for cutting and sucking. For the former operation the labrum and mandibulæ are sufficiently strong; while the maxillæ are, together with the labium, more or less produced, and by their union, form a sucker. They have two labial and two maxillary palpi. The eyes are large, and the ocelli three in number. The females are armed with a sting or piercer. Many of the species live in society, and exhibit, in the magnitude and regularity of their operations, the most striking displays of the attributes of the social instinct. The insects of this class admit of a division into two orders.

I. HYMENOPTERA TEREBRANTIA.—The females of this order are furnished with a produced ovipositor, frequently of sufficient strength to pierce the bodies in which the eggs are deposited. Among these, there are two families in which the piercer is tubular, and does not consist of separate valves. The *CHRYSIDÆ* have the piercer formed of the last rings of the body, retractile, and furnished with a small sting, as *Chrysis*, *Parnopes*, and *Cleptes*. In the *OXYURIDÆ*, the piercer is protuberant, without a sting, as *Oxyurus* and *Drynus*. In the remaining families the piercer consists of several valves. In some of these the abdomen is united to the thorax by a small portion of its transverse diameter. Among these there are some which have all the wings with ribs. The *ICHNEUMONIDÆ* have upwards of twenty joints in the antennæ, as in the following genera, *Ichneumon*, *Zorides*, *Crypturus*, *Agathis*, *Sigalphus*, and *Alysia*. In the *EVANIADÆ*, including *Evania* and *Fœnus*, the joints of the antennæ do not exceed fifteen in number. In others, the under wings are destitute of ribs. The *CYNIPSIDÆ* have the antennæ broken, with from six to twelve joints, as *Cynips*, *Leucopses*, *Chalcis*, and *Cynipsillum*. The *DIPLOLEPIDÆ* have the antennæ straight, with from eleven to sixteen joints, as *Diplolepis* and *Eucharis*.

The remaining families have the abdomen united to the thorax by the whole of its transverse diame-

ter. In the *SIREXIDÆ* the piercer consists only of three valves, the lateral ones serving as sheaths, as *Sirex* and *Oryssus*. In the *TENTHREDADÆ*, including *Tenthredo*, *Cimbex*, *Hylotoma*, *Xiphedria*, and *Pamphilus*, the piercer consists of four valves, the internal pair serrated.

II. HYMENOPTERA ACULEATA.—In this order are included such as have no ovipositor or piercer. The abdomen in the females, however, is usually furnished with a sting, and poison bags. The antennæ have thirteen joints in the male, and twelve in the female. These may be again reduced into two divisions. In the first, the feet are not formed for collecting pollen, and the first tarsal joints are cylindrical. Among these, there are two families, in which the ocelli are indistinct, and the neuters or females are apterous. The *FORMICADÆ*, including *Formica*, *Polyergus*, *Ponera*, *Myrmica*, *Atta*, and *Cryptocerus*, have males, females, and neuters, the last of which are apterous. They live in societies. The *MUTILLADÆ* have no neuters, and the females are apterous, as *Mutilla*, *Dorylus*, and *Labidus*. They are solitary. The others have the ocelli distinct, and are all furnished with wings. Among these there are some families in which the wings are always expanded. In the *SCOLIADÆ*, the first segment of the thorax is large, and extends above to the base of the upper wings, as in *Scolia*, *Tiphia*, *Sapyga*, *Thymus*, and *Pampilus*. In the *SPHEXIDÆ*, the first segment of the thorax is narrow and distant above from the base of the upper wings, as in *Sphex*, *Bembex*, *Larra*, *Crabro*, and *Philanthus*. There are other families in which the upper wings fold longitudinally. In the *MASARIDÆ*, the mandibles are narrow. There are only males and females, which are solitary, as *Masaris*, *Synagris*, *Eumenes*, and *Zethus*. In the *VESPADÆ*, which are social, there are males, females, and neuters; the mandibles are large, as *Vespa* and *Polistes*.

In nearly all the remaining genera, the hind legs are made for carrying pollen, having the first tarsal joint enlarged and compressed. Among these are some in which the tongue, or intermediate process of the labium, is as long, or longer than its sheath, and deflected when at rest. In the *Apidae*, which are social, there are males, females, and neuters, as *Apis*, *Melepona*, *Bombus*, *Euglossa*, *Eucera*, and *Anthophora*. While agreeing with the preceding in many particulars, the following genera are destitute of the expanded tarsal joint, for carrying pollen, *Systropha*, *Panurgus*, *Zylocopa*, *Ceratina*, *Megachile*, *Philcermus*, and *Nomada*. Others have the tongue shorter than the sheath, as the *ANDRENADÆ*, including *Andrena*, *Halictus*, and *Colletus*.

CLASS X.

DIPTERA.

The insects of this class have only two wings, and, in a few instances, none. Many species are furnished with *halleræ*, and *squamulæ*. The mouth is formed for suction. For this purpose, the labrum is more or less produced as a cover. The mandibulæ are obliterated, or in the form of threads. The maxillæ are produced into threads, and by their union in company with the mandibulæ, form the *syphon*. The labium is either double or single, and forms a

Insecta. sheath, destitute of joints, for the reception of the syphon. In some cases, there are two maxillary and two labial palpi. The larvæ are destitute of feet, and pass into pupæ *obtectæ*, or *coarctatæ*. In this numerous division, the labium, or sheath, is univalve, in others it is bivalve. We shall now advert to the first of these.

Among those with a univalvular sheath to the proboscis, there are some in which this sucking organ is entirely withdrawn, when not in use. Some of these have the sucker consisting of only the produced maxillæ. The *MUSCIDÆ* have the eyes sessile, at *Musca*, *Tephritis*, *Myoda*, *Macrocera*, *Scenopinus*. The *ACHIASIDÆ* have the eyes pedunculated, as *Achias*, *Diopsis*. The genus *Oestrus*, or Gad-fly, agrees with the muscidæ in habit, but the parts of the mouth are imperfect. Others have the sucker of four filaments, formed from the mandibulæ and maxillæ. In the *SYRPHIDÆ*, the front is produced like a beak, as *Syrphus*, *Psarus*, *Chrysotoxum*, *Cerea*, and *Rhingia*. In the *APHRITIDÆ*, the front is abbreviated, as *Aphritis* and *Milesia*. In the remaining genera of this group, the last joint of the antennæ is not simple, as in the preceding families, but annulated, and destitute of the lateral hair which they possess. These are termed *STRATIOMYDÆ*, and include the genera *Stratiomys*, *Oxycera*, and *Nemotelus*.

In the remaining families, with a univalvular sheath, the proboscis is always more or less protuberant. Among these, there are some which resemble the preceding families, in having only three joints in the antennæ. The *CONOPSIDÆ* have the sheath bent, and the sucker, with two filaments, as *Conops*, *Zodion*, *Homoxis*, *Bucentes*, and *Myopa*. The *BOMBYLIDÆ* have the sucker composed of from four to six filaments, and the sheath is destitute of large lips, as *Bombylus*, *Ploas*, *Mithrax*, *Nemestrina*, *Panops*, *Cyrtus*, *Acrocera*, *Astomella*; together with *Empis*, *Asilus*, and *Dioctria*. The *TABANIDÆ* have the sheath furnished with large lips, and the third joint of the antennæ distinctly annulated; as in *Tabanus*, *Pangonia*, and *Canomya*; together with *Pachystoma*, *Rhagis*, *Dolechopus*, and *Mydas*. Others have six joints or more in the antennæ. Among these the *BIRONIDÆ* have moniliform or perfoliated joints, about the length of the head, as *Bibio*, *Scatopsis*, and *Simulium*. The *TRIPULADÆ* have filiform or setaceous tentacula, as *Tipula*, *Cetenophora*, *Trichocera*, *Psychoda*, *Tanypus*, *Limonia*, *Hexatoma*, and *Culix*, all of which are destitute of ocelli;

together with *Asindulum*, *Ceroplatus*, *Mycetophila*, and *Rhyphus*, which are furnished with ocelli.

In the remaining genera of this class, the sheath of the sucker is bivalve. *HYPEROSCIDÆ* have the head distinctly divided from the thorax, as in *Hippobosca*, *Feronia*, *Ornithomyia*, *Craterina*, *Oxypterus*, and *Melophagus*. In the genus *Nycteribia*, the head is united with the thorax.

CLASS XI.

APTERA.

Into this class we have placed tribes of insects, which differ greatly from each other in the organs of digestion; but which do not agree with any of the preceding classes. They possess one common character in wanting wings, in all the stages of their existence. They may be divided into three orders, which by some are elevated to a primary rank.

I. *APTERA SECTORIA*.—The head, thorax, and abdomen intimately united. The mouth consists of two simple processes, the lowest of which is longest, and receives the superior one in a cavity in its upper side. On each side is a process of four joints covering the others. These unite to form a proboscis, which rests upon the sternum. Are the simple processes to be considered as the labrum and labium, and the articulated lateral ones as palpi, the mandibulæ and maxillæ being absent. The antennæ consist of four joints. This order contains at present only one genus, *Pulex* or Flea. There are several species. The *P. irritans* is every where common, and the *P. fasciatus* of Bosc may be met with on moles and mice.

II. *APTERA THYSANURA*.—The head in this and the following order is obviously separated from the thorax by a contraction or neck. The last segment of the body is furnished with long filaments. In the *LEPISMAIDÆ* the setæ of the tail are continually extended in the direction of the body, as *Lepisma* and *Forbicina*. In the *PODURIDÆ*, the setæ, when at rest, are folded under the body, as *Podura* and *Sminthurus*.

III. *APTERA PARASITA*.—The tail in this order is simple, or destitute of the filaments which distinguish the preceding. The *NIRMINÆ*, including numerous species of lice which infest birds, and included in the genera *Ricinus* and *Pediculus* of authors, have the mouth furnished with two teeth. The *PEDICULIDÆ* have a tubular proboscis, and include the genera *Pediculus*, *Phthirus*, and *Hæmatopinus*. (q. q.)

DESCRIPTION OF THE PLATE.

1. A, The stag-beetle (*Lucanus*) seen on the back. (Class *Coleoptera*.) B, The under side, exhibiting the position of the legs, and on one side the pits for the reception of the coxæ. C, The parts of the mouth displayed; *a*, the labrum, with its broad nasus; *b*, the mandibulæ; *c*, the maxillæ, with their jointed palpi; *d*, the bifid labium, with the two palpi and broad mentum.

2. The parts of the mouth of *Cimex nigricornis*. (Class *Hemiptera*.) *a*, The articulated labium, with the edges at each side, and the first joint of each of

the antennæ. This is the sheath for the other organs, and exhibits the groove on its oral surface; *b*, the sucker viewed from above, covered at the base for one-third of its length, with the subulated labrum, and exhibiting, at the extremity, the straight united tip of the maxillæ, and the recurved ends of the mandibulæ; *c*, is a view of the same parts separated, with the labrum removed, to exhibit the expanded roots of the mandibulæ and maxillæ, the small opening of the pharynx, and the pointed lingua before it and between the maxillæ.

Insecta
||
Interest.

3. Exhibits the parts of the mouth of the Nepa (Hepa neptunia, Savigny *Mémoires*, I. Pl. IV. fig. 3. Class Hemiptera), the labrum and palate being removed. The mandibulæ appear at the sides, their summits with reflected spiculæ, and their roots near the pharynx flask-shaped. The tongue is trifid at the apex, underneath which the maxillæ arise and exceed the mandibulæ. The labium exhibits the groove for the reception of the other parts, and the oval raised marks near its extremity are the vestiges of palpi.

4. Parts of the mouth of Papilio machaon. (Class Lepidoptera.) *a*, The head viewed in front, exhibiting the round eyes, one turn of the spiral proboscis, with the pilose labial palpi on each side; *b*, the tubular spiral maxillæ (which by their union form the proboscis), with the vestiges of palpi at their base. The circular apertures on each side, at the bottom

of the figure, indicate the insertion of the labial palpi; *c*, the cleft labium and the two palpi, the left one deprived of its scales; *d*, the minute labrum, with the mandibulæ on each side of it ciliated on their internal edge.

5. Parts of the mouth of the Lyndia cannurum of Savigny. (Class Lepidoptera.) *a*, The eyes, scaly spiral proboscis, and the four palpi; *b*, one of the maxillæ with its palpus; *c*, the labium and palpus; *d*, the labrum and mandibulæ.

6. The parts of the mouth of Tabanus italicus. (Class Diptera.) *a*, The mouth opened, or labrum and the mandibulæ and lingua separated, to exhibit the pharynx; *b*, one of the mandibulæ viewed laterally; *c*, one of the maxillæ with the articulated palpus, the last joint of which is greatly enlarged; *d*, the labium with its fleshy lips. (q.q.)

Interest.

I N T E R E S T

Rate of Interest. Is the sum which the borrower of a capital obliges himself to pay to the lender for its use.*

It was formerly universally believed that, in the event of all legislative enactments, fixing and regulating the rate of interest, being repealed, its increase or diminution would depend wholly on the comparative scarcity or abundance of money, or, in other words, that it would rise as money became scarce, and fall as it became more plentiful. Mr Hume was the first to point out the fallacy of this opinion (*Essay on Interest*), and to show that the rate of interest is not determined by the amount of the currency, but by the average rate of profit derived from the employment of capital. No doubt it most frequently happens that, when a loan is made, it is made in the currency of the country; this, however, is really of no consequence. There is obviously no difference between one individual furnishing another with 100 bushels of corn to be repaid at the expiry of a twelvemonth by the delivery of 104 or 105 bushels, or with as much money at 4 or 5 per cent. as would have purchased the corn. Besides, it is easy to perceive that the same identical sum of money might serve to negotiate an infinity of loans. Suppose A lends to X L.1000, which X immediately pays away to B for commodities of equal value; but B has no use for the money, and he, therefore, lends it to Y, who pays it away for commodities to C, who again lends it to Z, and so on; it is plain the borrowers, X, Y, Z, have really received a loan of commodities, or capital, from the lenders, A, B, C, worth three times (and it might have been worth three hundred or three thousand times) as much as the money employed in settling the transactions. According as the supply of currency, compared with the business it has to perform, is greater or less, we

are obliged to give a greater or lesser number of guineas or livres, pound notes, or assignats, for the commodities we wish to obtain. It is plainly, however, by the advantage or profit we expect to derive from the acquisition of the commodities which constitute capital, and not from the accidental, and, in this respect, unimportant circumstance of a larger or smaller number of pieces of gold or silver, or of bits of engraved paper being given for them, that the rate of interest, or the compensation given to the lender for the use of his stock, must be determined. It may perhaps be supposed, that when the quantity of metallic money is increased, goldsmiths, jewellers, &c. obtain the raw material for carrying on their business with greater facility; but this is not always the case, and, though it were, it would not affect the rate of interest. No coins are ever sent to the melting pot unless when the currency is either degraded or depreciated,—that is, unless it be deficient in weight, or relatively redundant in quantity. And it is clear that the inducement to promise a high or low rate of interest for loans of metallic money, which it was intended to work up into some species of manufactured goods, would depend not on the supply of such money, but on the profit to be derived from the operation,—a circumstance totally unconnected with the scarcity or abundance of coin.

It appears, therefore, that the rate of interest, at any given period, depends exclusively on the supply of real disposable capital, such as land, machinery, raw and manufactured products, &c. compared with the power of profitably employing it. An increase of metallic money adds only very inconsiderably, and an increase of paper money adds nothing whatever to the real capital of the country, or to the

* Interest: loyer d'un capital prêté; ou bien, en termes plus exacts, achat des services productifs que peut rendre un capital. Say, Tome II. p. 480, Ed. 1me.

material of which all loans are really composed. If an increase of paper money was equivalent to an increase of capital, bank notes could not be too much multiplied, and France would have been about twenty times as rich at the era of the assignats as at this moment! It is not denied that considerable mischief and derangement must always be experienced in a highly manufacturing and commercial country like Great Britain, when any sudden check is given to the facility with which discounts are generally obtained, or when the currency is suddenly contracted. But the *frottement* and inconvenience occasioned by a contraction of the currency could only be temporary. It is impossible it could have any lasting effect on the industry of the country. We should still possess the same amount of real capital; and as neither its productive power, nor the liberty to transfer it from one individual to another, would be at all impaired, the real revenue of the state would continue as great as ever, and the same, or a greater amount of stock might be disposed of by way of loan. Money prices would certainly fall proportionably to the reduction of the currency; or, which is the same thing, the value of commodities would henceforth have to be ascertained by comparing them with a smaller number of bits of gold or paper. But, in every other respect, the business of society would continue exactly on its former footing; and without some change in the rate of profit, on which fluctuations in the value of money have almost no effect, the rate of interest would continue invariable.

Mr Ricardo has set this principle in a clear and striking point of view. "The rate of interest," he observes in answer to those who had contended that it would be increased by a diminution of the discounts of the Bank of England, "is not regulated by the rate at which the Bank will lend, whether it be 5, 4, or 3 per cent., but by the rate of profit which can be made by the employment of capital, and which is totally independent of the quantity and of the value of money. Whether a bank lend one million, ten millions, or a hundred millions, they would not permanently alter the market rate of interest; they would alter only the value of the money which they thus issued. In one case, ten or twenty times more money might be requested to carry on the same business, than what might be required in the other. The applications to the Bank for money, then, depend on the comparison between the rate of profits that may be made by the employment of it, and the rate at which they are willing to lend it. If they charge less than the market rate of interest, there is no amount of money which they might not lend; if they charge more than that rate, none but spendthrifts and prodigals would be found to borrow of them. We accordingly find, that when the market rate of interest exceeds the rate of 5 per cent. at which the bank uniformly lend, the discount office is besieged with applicants for money; and, on the contrary, when the market rate is even temporarily under 5 per cent., the clerks of that office have no employment." (*Principles of Political Economy*, 1st edit. p. 511.)

It is foreign to the object of this article to enter into any detailed examination of the causes which

tend to elevate or depress the rate of profit. Wherever diversity of opinion may be entertained respecting them, it is abundantly evident that the rate of interest afforded for the use of borrowed capital must be proportionable to the profits which might be derived from its employment. In the United States, the market rate of interest varies from 10 to 14 per cent.; and in Holland, previously to the invasion of the French in 1794, it did not exceed 2 or 3 per cent. The immense extent of fertile and uncultivated land in America, the lowness of taxation, and the absence of all restrictive regulations, naturally occasion high profits, and consequently high interest; while the sterility and limited extent of the soil of Holland, the excessive load of taxes, laid equally on necessaries and luxuries, and the injudicious restraints imposed on various branches of commerce, by rendering it impossible to derive large returns from capital, proportionably sink the rate of interest. Had the soil of Holland been as fertile, and taxation as light as in the United States, profits and interest would, notwithstanding the abundant supply of capital, have been equally high in the one Republic as in the other. It is not by the absolute amount of the stock of a country, but by the comparative facilities for its advantageous employment, that the compensation or interest which a borrower can afford for its use must always be regulated. Previous to the termination of the late war, the market rate of interest in this country, for sums which could not be immediately demanded, fluctuated from 5 to 12 per cent. It has since fallen to 4 or 5 per cent.; a decline which has not, certainly, been occasioned by any sudden increase of capital, but by the extraordinary depression of commerce, and the consequent impossibility of investing stock so as to yield as large a profit as it did during the period when we engrossed almost the whole trade of the world.

Besides, such variations as are proportionable to variations in the general and average rate of profit, and which equally affect all loans, the rate of interest must vary according to the degree of security afforded for the repayment of the principal, and the duration of the loan. No capitalist would lend on the personal security of a gunpowder manufacturer, and on mortgage over a valuable estate, at the same rate of interest. The extraordinary hazard of the gunpowder trade exposes the stock invested in it to an extreme degree of risk. It may be dissipated in an instant; and the power of the borrower to refund the capital he had borrowed annihilated for ever. A lender of money on mortgage is almost entirely relieved from such contingencies. The owner of an estate on which a loan is secured may become bankrupt, but the estate itself will remain, and may be either sold or taken possession of by the lender. It is plain, therefore, that there must be a very great difference in the rate of interest paid by those whose security for the repayment of the principal is so exceedingly different. The gunpowder manufacturer, besides paying a rate, or per centage, equivalent to the common and average rate of interest derived from the most secure investments, would have to pay an additional rate, which, although it might not be designated by that name, would really

INTEREST.

Interest. constitute a *premium* of insurance proportioned to the greater risk to which the lender was exposed of losing his principal. The preferable security offered by the landholder would relieve him from the necessity of paying any considerable premium, or excess of interest, on account of risk; and, of course, he would be able to borrow at so much less than the manufacturer. We should mistake, however, if we supposed that the latter was thus placed in a comparatively disadvantageous situation. He would be completely indemnified for the greater risk to which his stock was exposed, and for the higher rate of interest which he was, in consequence, obliged to pay, by the greater *gross profits* he would derive from his business. The constantly operating principle of competition will not permit, taking every thing into account, a greater *net profit* to be permanently derived from one department of industry than from another. But those who invest their stock in employments of more than ordinary hazard, must be able to dispose of their produce at such a price as will yield them the common and average rate of profit, besides affording a surplus adequate to insure their stock against the extra risk to which it is exposed. If this were not the case, no capitalist would place his property in a state of comparative danger, and no undertakings of a hazardous nature would be entered into. Wherever there is risk, that risk must be compensated. And it may, and very frequently does, happen that the manager of a hazardous branch of industry, paying from 10 to 20 *per cent.* for borrowed capital, is realizing a larger *net profit* than the landlord who has purchased an estate with money for which he only pays 3 or 4 *per cent.**

But, supposing the securities to be equal, capital lent for *short* periods, or in such a way that the lender may obtain possession of it *at pleasure*, will always bring a lower rate of interest than capital lent for a considerable, or definite, period. No borrower could afford to pay so high a rate of interest for a capital of whose productive services he might be deprived in an instant, and which he could not, therefore, venture to invest in any employment from which it might not be easily withdrawn, as for a capital lent for a fixed period, especially if that period was of considerable length. But here, as in every other case, the real interests of the borrower and lender coincide. The same circumstances which prevent a borrower from giving as high a rate of interest for a loan payable on demand as if it were payable at a fixed and distant term, induces the lender to rest satisfied with a smaller compensation in the one case than in the other. We wish to be able to exercise a complete command

over our capital. No merchant would ever consent to lend his stock on mortgage. If he did, he would no longer be able to carry on his business with advantage. He would be deprived of all power of speculating; and, although this might, in many instances, be for his advantage, yet the flattering opinion which every one entertains of his own abilities and good fortune, would but seldom allow him to doubt of its being a very material disadvantage. It is by this principle that we are able to account for the comparatively low rate of interest at which banking companies, who pay the sums deposited with them on demand, and governments, whose circumstances are perfectly desperate, are able to borrow. A stockholder's mortgage,—his claim on the revenue of the country,—can be immediately converted into cash at the current prices. And, however much the majority of the public creditors may be impressed with a conviction of the inability of the state to discharge *all* the claims upon it, every particular individual, confident in his own good fortune, foresight, and acuteness, flatters himself with the idea that *he*, at least, will be able to predict the coming tempest, and that *he* will be able to sell out before a national bankruptcy.

Instead, however, of leaving the rate of interest to be adjusted by the unfettered competition of the borrowers and lenders, on the principles we have thus briefly explained, the governments of most countries have interfered either to prohibit the taking of interest altogether, or to fix certain rates which were declared legal to exact, at the same time that any excess over these rates was declared to be *usury*, and prohibited under the severest penalties. In the rude and unenlightened ages in which these enactments had their origin, the precious metals, then the only species of money, were considered as uninfluenced by the same principles which regulate the value of other products. Being used both as standards whereby to ascertain the comparative value of different commodities, and as the equivalents for which they were most frequently exchanged, they acquired a factitious importance, not merely in the estimation of the vulgar, but in that of persons of the greatest discernment. The simple consideration that all buying and selling is really nothing more than the bartering of one commodity for another,—of a certain quantity of corn or beef, for example, for a certain quantity of gold or silver, and *vice versa*, was entirely overlooked. The attention was gradually transferred from the money's worth to the money itself, and the wealth of states and of individuals came to be measured, not by the abundance of their disposable

* This principle is never lost sight of in bargaining for loans. In Athens, the rate of interest was not regulated by law; and it is distinctly mentioned in ancient authors, that the average rate of interest paid by those who employed their stock in the shipping trade with the countries situated on the Euxine and Mediterranean Seas, amounted, on account of the hazard of the voyage, to about 30 *per cent.*, while bankers, agriculturists, and others, whose security was preferable, paid only about 12 *per cent.* Say, in noticing this striking fact, supposes that the 30 *per cent.* was charged by the voyage; and that, as two voyages to the Crimea, or Sicily, might be made annually, *maritime* interest really amounted at Athens to 60 *per cent.* There does not, however, appear to be the least ground for this assertion. It is the average annual rate of interest that is always spoken of.—(*Travels of Anacharsis*, Vol. IV. p. 368, Eng. trans.; *De Puissances Recherches sur les Grecs*, Tom. I. p. 287; Say, Tom. II. p. 132.)

Interest. produce,—by the quantity or value of the commodities with which they could afford to purchase the precious metals,—but by the *quantity of these metals* actually in their possession. Because it sometimes happened that the holders of ordinary commodities were unable easily to dispose of them at any price, while money was always sure to find a ready and advantageous market, it was considered as something mysterious,—as a real *marchandise par excellence*. We cannot, therefore, be surprised at the measures to which the erroneous opinions entertained respecting it necessarily led; or that efforts should have been made to protect the interests of those who were unprovided with so powerful an instrument, from becoming a prey to the encroachments of their more fortunate neighbours. Every individual was allowed freely to dispose of his corn, cattle, land, &c.; but it was imagined there was something peculiar in money, and that the desire to obtain it was so great, that, unless the lenders were restrained in their demands, they would, by taking advantage of the necessities of the borrowers, infallibly ruin them, and engross the whole property of the country.

Another source of the prejudice against stipulating for interest must be sought for in the dislike so universally entertained in remote ages to accumulation. There can be no accumulation without economy,—without a saving of income,—and this was then not only considered as indicative of a sordid and avaricious disposition, but as being positively hurtful. Before the nature and functions of capital were properly understood, it was believed it could not be increased otherwise than by injuriously abstracting a portion of the national revenue, and that any advantage it might give to the proprietor, must have been obtained at the public expense. It did not occur to our ancestors, that an individual who, by his economy, has accumulated stock, has really added to the wealth of the state, without diminishing that of others; nor were they aware that this stock, when afterwards expended, as is almost always the case, in the support of productive industry, would afford the means of producing an increased income. But, reckoning as they did, the savings of individuals as so much withdrawn from the public income, it was natural enough that they should endeavour to limit the advantage to be derived from their employment.

Much, also, of the prejudice against bargaining for interest, so prevalent in the middle ages, may be traced to the authority of some texts of scripture, which were understood entirely to prohibit its exaction. It has, however, been shown, that these texts will not really bear this interpretation; but, supposing they had, nothing, it is plain, could be more absurd than to consider the municipal regulations of a people placed in such peculiar circumstances as the Jews, as general and fixed principles, applicable in all ages and countries.

But, whatever may have been the causes of the efforts so generally made to regulate and limit the rate of interest, it is certain that, far from succeeding in their object, they have had a precisely opposite effect. Should a borrower find it for his advantage to offer 6, 7, or 8 *per cent.* for a loan—and, unless it were for his advantage, nothing could possibly in-

Interest. duce him to make such an offer—what right has the legislator to interfere, and to prohibit the lender from receiving, and the borrower from paying, more than 4 or 5 *per cent.*? Such an interference is not only uncalled for and unnecessary, but it is, in the highest degree, prejudicial. Restrictive laws, instead of reducing, have uniformly contributed to raise the rate of interest. Nor is this any thing but what might have been foreseen and expected. It is plain no law can be so framed as to prevent a borrower from offering a higher rate of interest than what is fixed by statute; and, if the lender had implicit confidence in the secrecy and solvency of the borrower, he might accommodate him with the sum wanted, without requiring any additional interest or *premium of insurance*, because of the danger of entering into what the law declares to be an *illegal transaction*: but this must be a very rare case. Gratitude, and a sense of benefits received, are, unfortunately, when they come into contact with self-interest, but slender securities for honourable conduct. Numberless unforeseen events occur to weaken and dissolve the best cemented friendships; and a transaction of this kind would undoubtedly afford an additional source of jealousies and divisions. In such matters, indeed, men are more than usually sharp-sighted, and are very little disposed to trust to moral guarantees for the security of their property. But neither the threatenings of the law, nor the powerful inducements which it holds out to dishonest debtors to break their engagements, and treacherously to recede from the stipulations to which they had agreed, have been able to prevent, or even greatly to lessen, what are termed *usurious bargains*. Their only effect has been, to oblige the lender to demand, and the borrower to bind himself to pay, a higher rate of interest than would otherwise have been required. A bargain for more than the statute rate of interest being declared illegal, the lender is thus exposed to an additional *risk*. But no person will gratuitously place his fortune in a situation of comparative hazard; and, therefore, the sum necessary to cover this risk, must be proportioned to the greater or less anxiety on the part of government to prevent and punish such bargains; or, in other words, the rate of interest is invariably increased according as the laws intended to reduce it become more severe, and diminished according as they are relaxed!

Thus a capitalist might be inclined to lend a sum at 6 or 7 *per cent.*; but, as the law declares that any individual who shall stipulate for more than 5 *per cent.* shall, if detected, forfeit *three times the principal*, it is clear, provided there was no method of defeating this statute, that there must be an end of all borrowing, except when the market rate of interest was below the statutory rate. Whenever it was above that rate, no person would be able to obtain a single farthing by way of loan. There could, then, be no transference of capital. It would continue locked up in the same hands; and the national property and welfare would, in consequence, suffer severely. Luckily, however, the mutual interest and ingenuity of borrowers and lenders have always proved an overmatch for the enactments of the law.

The attempts to limit and restrain the rate of interest, instead of reducing, have contributed to raise it.

Interest

These have done nothing but fetter the transference of stock, and force the borrowers to pay a higher rate of interest for it. What might have been borrowed at 6 *per cent.*, had there been no hazard from anti-usurious statutes, is, on account of that hazard, raised to perhaps 8 or 10 *per cent.*; and, what is still worse, a contempt for the institutions of society, and a habit of carrying on business in a secret and underhand manner, is generated. The odium which attaches to a positively pernicious regulation weakens the respect which would otherwise be felt for those which are acknowledged to be advantageous; and that spirit of frankness, openness, and sincerity, which, wherever it predominates, is so highly valuable, is cramped in its development, or altogether supplanted, by duplicity, extortion, and cunning.

Effect of the Usury Laws in Rome:

These conclusions do not rest on theory only, but are supported by a constant and uniform experience. At Rome, during the period of the Republic, the ordinary rate of interest was excessively high. The debtors, or plebeians, were every now and then threatening to deprive their creditors, who were generally of the patrician order, not only of the interest of their capital, but of the principal itself. Repeated instances occurred to show that these were not mere empty threats; and the patricians were, therefore, obliged to indemnify themselves, by means of a corresponding *premium*, for the risks to which they were exposed. "Des continuel changements," says Montesquieu, "soit par des loix, soit par des plebiscites, naturaliserent à Rome l'usure; car les créanciers, voyant le peuple leur débiteur, leur législateur, et leur juge, n'eurent plus de confiance dans les contrats. Le peuple, comme un débiteur dé-cré-dité, ne tentoit à lui prêter que par des gros profits; d'autant plus que, si les loix ne venoient que de tems en tems, les plaintes du peuple étoient continuelles, et intimidoient toujours les créanciers. Cela fit que tous les moyens honnêtes de prêter et d'emprunter furent abolis à Rome, et qu'une usure affreuse, toujours foudroyée, et toujours renaissante, s'y établit. Le mal venoit de ce que les choses n'avoient pas été menagées. Les loix extremes dans le bien font naître le mal extrême: il fallut payer pour le prêt de l'argent, et pour le danger des peines de la loi." (*Esprit des Loix*, Liv. XXII. chap. 21.)

In the East:

In Mahometan countries, notwithstanding the positive prohibition in the Coran, the ordinary rate of interest is at least ten or twenty times as high as its ordinary rate in Europe. "L'usure augmente dans les pays Mahometans d proportion de la sévérité de

la défense: le prêteur s'indemnise du peril de la contravention." (*Esprit des Loix*, Liv. XXI. chap. 19.)

During the middle ages, the average rate of profit in the middle ages: could not be much higher than at present: "But the clamour and persecution raised against those who took interest for the use of money was so violent, that they were obliged to charge it much higher than the natural price, which, if it had been let alone, would have found its level, in order to compensate for the opprobrium, and frequently the plunder, which they suffered; and hence the usual rate of interest was what we should now call most exorbitant and scandalous usury." (Macpherson's *History of Commerce*, Vol. I. p. 400.) The extraordinary risks to which lenders were exposed rendered the premium of insurance on all sorts of capital excessively high; for, of the 50, and even 100 *per cent.*, which borrowers then frequently engaged to pay as interest, not more than 8 or 10 *per cent.* can properly be said to have been given for the productive services of capital. The rest must be considered as a *bonus*, to compensate the lender for the hazard he encountered of losing the principal itself.*

In France the rate of interest was fixed at 5 *per cent.* so early as 1665; and this, a few short intervals only excepted, continued to be the legal rate until the Revolution. Laverdy, in 1766, reduced it from 5 to 4 *per cent.* Instead, however, of the market rate being proportionably reduced, it was raised from 5 to 6 *per cent.* Previously to the promulgation of the edict loans might have been obtained on good security at 5 *per cent.*; but an additional *per cent.* was now required to cover the risk of illegality. This caused the speedy abandonment of the measure. (Storch, *Traité d'Economie Politique*, Tome III. p. 187.)

The same thing happened in Livonia in 1786, when the Empress Catherine reduced the legal rate of interest from 6 *per cent.* to 5. Hitherto, says Storch, (*in loco citato*), those who had good security to offer, were able to borrow at 6 *per cent.*; but henceforth they had to pay 7 *per cent.* or upwards. And such will be found to have been invariably the case wherever governments have interfered to reduce the statutory below the market rate of interest.

From the earliest period of the history of England, down to the reign of Henry VIII., the taking of interest was absolutely forbidden to all persons within the realm except Jews and foreigners; who, nevertheless, were frequently plundered for the sake of enriching the Crown, under the miserable

* It is impossible to form any very accurate estimate of the rate of profit in the middle ages, yet several striking facts may be adduced in support of the opinion advanced in the text. At Verona, in 1228, the interest of money was fixed by law at 12½ *per cent.* Towards the end of the fourteenth century, the Republic of Genoa paid only from 7 to 10 *per cent.* to her creditors; and the average discount on good bills at Barcelona, in 1435, is stated to have been about 10 *per cent.* But while the rate of interest in Italy and Catalonia, where a considerable degree of freedom was allowed to the parties concerned in bargaining for a loan, was thus comparatively moderate, it was, in despite of its total prohibition, incomparably higher in France and England. Matthew Paris mentions, that, in the reign of Henry III., the debtor paid 10 *per cent.* every two months; and this, though absolutely impossible as a general practice, may not have been very far from the average interest charged on the few loans that were then contracted for.—(Hallam's *History of the Middle Ages*, Vol. III. p. 402.)

Interest. pretext of punishing them for what were then called their "hellish extortions." The disorders occasioned by this ruinous interference on the part of Government at length became so obvious, that, notwithstanding the powerful prejudices to the contrary, a statute was passed in 1546 (37th Hen. VIII. cap. 7.), legalizing the taking of interest to the extent of 10 *per cent. per annum*; and this, because, as is recited in the words of the act, the statutes "prohibiting interest altogether have so little force, that little or no punishment hath ensued to the offenders." In the reign of Edward VI. the horror against taking interest seems to have revived in full force; for, in 1552, the taking of *any* interest was again prohibited "as a vice most odious and detestable," and "contrary to the word of God." But, in spite of this tremendous denunciation, the ordinary rate of interest, instead of being reduced, immediately rose to 14 *per cent.*; and continued at this rate, until, in 1571, an act was passed (13th Eliz. cap. 8), repealing the act of Edward VI., and reviving the act of Henry VIII., allowing 10 *per cent.* interest. In the preamble to this act, it is stated, "that the prohibiting act of King Edward VI. had not done so much good as was hoped for; but that rather the vice of usury hath much more exceedingly abounded, to the utter undoing of many gentlemen, merchants, occupiers, and others, and to the importable hurt of the commonwealth." This salutary statute was opposed, even by those who, it might have been expected, would have been among the first to emancipate themselves from the prejudices of the age, with all the violence of ignorant superstition. Dr John Wilson, a man famous in his day, and celebrated for the extent and solidity of his learning, stated, in his place in the House of Commons, that "it was not the amount of the interest taken that constituted the crime; but that all lending for any gain, be it ever so little, was wickedness before God and man, and a damnable deed in itself, and that there was no mean in this vice any more than in murder or theft!" In order to quiet the consciences of the Bench of Bishops, a clause was actually inserted, declaring *all* usury to have been forbidden by the law of God, and to be, in its nature, sin, and detestable! When first enacted, this statute was limited to a period of five years; but, "forasmuch as it was by proof and experience found to be very necessary and profitable for the commonwealth of this realm," it was, in the same reign, made perpetual. (39th Eliz. cap. 18.)

In the 21st of James I. the legal rate of interest was reduced to 8 *per cent.*, by an act to continue for seven years only, but which was made perpetual in the succeeding reign. (3d Car. I. cap. 4.) During the commonwealth, the legal rate of interest was reduced to 6 *per cent.*; a reduction which was afterwards confirmed by the act 12th Car. II. And, finally, in the reign of Queen Anne, a statute (12th Anne, cap. 16) was framed, reducing the rate of interest to 5 *per cent.*, at which it now stands.

In the preamble to this statute, it is stated, that, "whereas the reducing of interest to ten, and from

thence to eight, and thence to six in the hundred, hath from time to time, by experience, been found very beneficial to the advancement of trade and the improvement of lands; it is become absolutely necessary to reduce the high rate of interest of 6 *per cent.* to a nearer proportion to the interest allowed for money in foreign states." It was for these reasons enacted, that all bargains or contracts, stipulating for a higher rate of interest than 5 *per cent.* should be utterly void. And "that all persons who should after that time receive, by means of any corrupt bargain, loan, exchange, chevizance, or interest of any wares, merchandise, or other thing whatever, or by any deceitful way or means, or by any covin, engine, or deceitful conveyance for the forbearing or giving day of payment, for one whole year for their money or other thing, above the sum of L.5 for L.100 for a year, should forfeit, for every such offence, the triple value of the monies or other things so lent, bargained," &c.

In Scotland, previously to the Reformation, no laws regulating the rate of interest could be legally exacted for money. But this great event, by weakening the force of those religious prejudices, which had chiefly dictated the laws prohibiting interest, occasioned the adoption of sounder opinions on the subject, and led to the enactment of the statute of 1587 (11th Parl. Jac. VI. cap. 52), which legalized the taking of interest to the extent of *ten per cent.* In 1633 the legal rate was reduced to *eight per cent.*, and, in 1661, to *six per cent.* The statute of Queen Anne, reducing the rate of interest to 5 *per cent.*, extended to both kingdoms.

The statutes prohibiting the taking of interest in Ireland were not repealed until 1635, when, by the statute 10th Car. I. cap. 22, liberty was given to stipulate for interest to the extent of *ten per cent.* In 1704 this rate was reduced to *eight per cent.*; in 1722 it was reduced to *seven per cent.*; and, in 1782, it was further reduced to *six per cent.*, at which it has since continued fixed.

It has been observed by Dr Smith, that the different statutory regulations, reducing the rate of interest in England, were made with great propriety. Instead of preceding, they followed the fall which was gradually taking place in the market rate of interest; and, therefore, did not contribute, as they otherwise must have done, to raise the rate which they were intended to reduce. Sir Josiah Child, whose celebrated Treatise, recommending a reduction of interest to *four per cent.* was published about 1670, states positively, that the goldsmiths in London, who then acted as bankers, could obtain as much money as they pleased, upon their servants' notes only, at 4½ *per cent.* The supposed insecurity of the revolutionary establishment, and the novelty of the practice of funding, occasioned the payment of a high rate of interest for a considerable portion of the sums borrowed by the public in the reigns of William III. and Anne; but private persons, of undoubted credit, could then borrow at less than 5 *per cent.* During the reign of George II. the market rate of interest fluctuated from 3 to 4 and ½ *per cent.*

On the 18th December 1752, the *three per cents.* brought the highest price they have hitherto reached,

Interest. from obtaining loans from capitalists of the highest character, and force them to have recourse to those who are less scrupulous. Supposing the market rate of interest to be 6 or 7 per cent., an individual, in ordinary good credit, might, were the usury laws abolished, easily obtain a loan at that rate. But the law having declared, that no more than 5 per cent. shall be taken, and consequently having affixed a species of stigma to those lenders who bargain for a higher rate, necessarily excludes the rich and more respectable capitalists from the market, and obliges borrowers to resort to those of an inferior character, who, in addition to the premium for the risk incurred by entering into an illegal transaction, must receive an indemnification for the odium which, in such cases, always attaches to the lender. It is idle and ridiculous to attempt to secure individuals against the risk of imposition in pecuniary, more than in any other species of transactions. But, although the object were really desirable, it could not possibly be obtained by such inadequate means. The usury laws generate the very mischief they are intended to suppress. Far from diminishing, they most unquestionably multiply usurious transactions in a tenfold proportion, and powerfully aggravate all the evils they were designed either to mitigate or remove.

Nothing can be more unreasonable, or more entirely unfounded, than the clamour that has been set up against usurers, as money lenders are sometimes termed, because of their exacting a higher rate of interest than ordinary from prodigals and spendthrifts. This surely is the most proper and efficient check that can be put upon the thoughtless or unprincipled extravagance of such persons. Supposing the security of a prodigal and of an industrious man to be nearly equal, and this can scarcely ever be the case, does not the capitalist, who would lend to the latter at a lower rate of interest than he would lend to the former, confer a real service on his country? Does he not prevent those funds which ought to be employed in supporting useful labour, and in adding to the real wealth of the nation, from being wasted in ridiculous extravagances or boisterous dissipation?

But, perhaps, we shall be told, that this is mistaking the object of the usury laws—that they were not intended to force capitalists to lend to spendthrifts at the same rate of interest as to industrious persons, but to protect the prodigal and unwary from the extortion of usurers, by declaring any stipulation between them for more than a given rate of interest to be null and void. But why all this solicitude about the least valuable class of society? Why fetter and restrict the free circulation of capital among those who would turn it to the best account, lest any portion of it might chance to fall into the hands of those who would squander it away? If the prevention of prodigality be an object of sufficient importance to justify the interference of the Legislator, why not at once put the prodigal under an *interdict*? This is the only way in which it is possible to restrict him. It is not so much by borrowing money at high interest, as by contracting debts to merchants, on whose charge there is no

check, that spendthrifts generally run through their fortunes. Mr. Bentham has justly observed, that so long as a man is looked upon as one who will pay, he can much easier get the goods he wants than he could the money to buy them with, though he were content to give for it twice or thrice the ordinary rate of interest. How ridiculous is it, then, to stimulate this natural facility of purchasing, to permit prodigals to borrow (for it is really borrowing) the largest supplies of food, clothes, &c. at 20, 30, or even 100 per cent. interest, at the same time that we inflict a real injury on every other class of society, rather than permit them to borrow the smallest supply of money at more than 5 per cent.! Instead of being of any service, this restriction is evidently injurious to the prodigal. It narrows his choice, and drives him from a market which might have proved much less disadvantageous, to one in which no disgrace attaches to the exaction of the most exorbitant interest, and where he can scarcely escape being ruined.

Neither is the outcry raised against capitalists for taking advantage of the necessities of industrious individuals one whit better founded than that which is raised against them for taking advantage of the extravagant and thoughtless disposition of the prodigal or the simple. According as a person has a character for sobriety, and for punctuality in making his engagements, and according to the presumed state of his affairs at the time, so will he be able to borrow. To say that a capitalist took advantage of the necessities of any individual, is only saying that he refused to lend to a person in suspicious or necessitous circumstances, at the same rate of interest he would have done had he been in high credit; or, which is the same thing, had there been no risk of losing the principal; and had he not acted in this manner, should we not have justly considered him as a fool or a madman?

But, as has already been shown, whatever may be the extortion of lenders, the usury laws afford no means of checking it, on the contrary, they compel the borrowers to pay, over and above the common rate of interest, a premium sufficient to indemnify the lender for the risk and odium incurred in *breaking them!* They attempt to remedy what is not an evil, and what, consequently, ought not to be interfered with; and in doing this they necessarily create a real grievance. What should we have thought of an act of Parliament to compel the underwriters to insure a gunpowder magazine and a salt warehouse on the same terms? Yet this would not have been in any respect more absurd than to enact that the same rate of interest should be charged on capital lent to those whose security is widely different.

Luckily we are not left to infer from general principles, however well established, the many advantages that would result from a repeal of the laws limiting the rate of interest. The case of Holland furnishes a practical and striking proof of the correctness of the theory we have been endeavouring to establish. It is an undoubted fact, that the rate of interest has been, for a very long period, lower in Holland than in any other country in Europe, and yet Holland is the only country in which usury laws are altogether

Interest.

Interest, unknown, whether capital was lent or deposited, and borrowers to pay, and lenders to receive. Notwithstanding all the violent changes of the government, and the extraordinary fluctuations of her financial position in the course of the last twenty years, the rate of interest in Holland has continued comparatively steady. During the whole of that period, persons who could offer unexceptionable security have been able to borrow at from 3 to $3\frac{1}{2}$ per cent.; nor has the average rate of interest charged on capital, advanced on the worst species of security, ever exceeded 6 or 7 per cent., except when the government was negotiating a forced loan. But, in this country, where the law declares that no more than 5 per cent. shall be taken, the rate of interest for capital advanced on the best landed security has, in the same period, varied from 5 to 16 or 17 per cent., or five times as much as in Holland. Surely this ought to put to rest all doubts as to the impolicy and the inefficiency of the usury laws.

In France the usury laws were abolished at the Revolution; and it is distinctly stated, that their abolition was not attended by any rise of interest. (Storch, *Economie Politique*, Tome III. p. 187.) According to the Code Napoléon only 6 per cent. interest is allowed to be taken in commercial affairs, and 5 per cent. when money is advanced on the security of real property. There is not, however, any difficulty in evading this law. The method, resorted to for this purpose, is to give a *bonus* before completing the transaction, or, which is the same thing, to frame the obligation for the debt for a larger sum than was really advanced by the lender. None of the parties, particularly interested, can be called to swear to the fact of such a *bonus* being given, so that the transaction is unimpeachable, unless a third party, who was privy to the settling of the affair, can be produced as a wit-

ness. The Bank of France never discounts at a higher rate of interest than 5 per cent., but sometimes at a lower rate.

In Hamburg, the rate of interest is quite unrestricted; or, if there be a written law restraining it, high; it has become altogether obsolete. The rate, therefore, varies according to circumstances. Occasionally it has been at 7, 9, and even 10 per cent.; and, in 1799, a period of great mercantile embarrassment and insecurity, it was as high as 14 per cent. Generally, however, the rate of discount on good bills does not exceed 4 or 5 per cent. (*Report on Usury Laws*, p. 46.)

In Russia the legal rate of interest is 6 per cent. In Russia; But, as Russia is a country capable of much improvement, and where there are very great facilities for the advantageous employment of capital, the market rate of interest is invariably higher than the statute rate, and the law is as constantly as it is easily evaded. (*Ibid.* and Storch, Tome III. p. 207.)

At Trieste, and throughout the Austrian empire in Austria; general, the usual rate of interest is fixed by law at 6 per cent.; but capital can seldom be obtained for less than 8 or 10 per cent. (*See Report ubi supra.*)

At Leghorn the ordinary rate of interest is $\frac{1}{2}$ per cent. per month, or 6 per cent. per annum; but there is no law to prevent the taking of a higher rate. (*Ibid.*)

In Spain the ordinary rate of interest is 6 per cent.; but no law exists against taking a higher rate, and it seldom falls below 5, or rises above 7 per cent. (*Ibid.*)

In the United States legal interest is fixed at 6 per cent., but the market rate fluctuates from 10 to 12 per cent. Mr. Birkbeck informs us, are now making various parts of the Union, particularly in Virginia and North Carolina, to do away the

* Strictly speaking, this applies only to the state of Holland previously to the Revolution in 1795. The enactments of the Code Napoléon were subsequently introduced; but it appears from the Report of the Parliamentary Committee on the Usury Laws, that they have not, in any instance, been acted upon.

† The general rate of discount in Holland is from 4 to 5 per cent., and occasionally from 3 to $3\frac{1}{2}$ per cent., but very seldom below. During the Revolution it has been at 6 and 7 per cent., and even at 8, but this has been generally owing to some forced financial operation on account of the government, and has never been of long duration. The following is the average rate of discount at Amsterdam and Rotterdam from 1795 to 1817:

1795—4,	$4\frac{1}{2}$,	5,	6,
1796—4,	$4\frac{1}{2}$,	5,	6,
1797—4,	$4\frac{1}{2}$,	5,	$5\frac{1}{2}$, 6, 9, 12,
1798—4,	$4\frac{1}{2}$,	5,	5,
1799—3,	$4\frac{1}{2}$,	$4\frac{1}{2}$,	5,
1800—4,	$4\frac{1}{2}$,	5,	6,
1801—4,	$4\frac{1}{2}$,	5,	6,
1802—4,	5,	$5\frac{1}{2}$,	6,
1803—4,	5,	$5\frac{1}{2}$,	6,
1804—4,	$4\frac{1}{2}$,	5,	$5\frac{1}{2}$, 6,
1805—4,	5,	$5\frac{1}{2}$,	6, 9,
1806—4,	$4\frac{1}{2}$,	5,	$5\frac{1}{2}$, 6, 9,

1807—4,	$4\frac{1}{2}$,	5,	6,
1808—4,	$3\frac{1}{2}$,	$4\frac{1}{2}$,	5, 6,
1809—4,	$4\frac{1}{2}$,	5,	6,
1810—4,	$4\frac{1}{2}$,	5,	6,
1811—3,	$3\frac{1}{2}$,	4,	5,
1812—3,	$3\frac{1}{2}$,	4,	5,
1813—3,	$3\frac{1}{2}$,	4,	5, 6,
1814—4,	5,	$5\frac{1}{2}$,	5, 6, $6\frac{1}{2}$,
1815—5,	6,	$6\frac{1}{2}$,	7,
1816—5,	$5\frac{1}{2}$,	6,	$6\frac{1}{2}$, 7,
1817—5,	$5\frac{1}{2}$,	6,	

"The Bank of Amsterdam never discounts at a higher rate than 5 per cent.; but they discount at a lower rate, and vary their discounts according to the abundance of capital, never exceeding 5 per cent., and occasionally as low as $3\frac{1}{2}$ and 3."—Mr. Holland's evidence, *Report of the Committee on the Usury Laws*.

Interest. restraints on usury, which, as he justly observes, "operate merely as a tax on the needy borrower."—*(Letters from Illinois, p. 36.)*

Usury Laws don't reach the Government. If usury laws are to have any existence, they ought certainly to be made to operate on the greatest of all borrowers—on those who do not borrow on their own credit, but on that of others. Is it not the extreme of folly, that, while an industrious manufacturer, or agriculturist, is prevented from giving more than 5 per cent. for capital, which he might be able to invest so as to yield 10 or 12 per cent., Government should be allowed to borrow at 6, 8, 10, or 20 per cent.? What is this, but holding out a bait to loan-mongers, and causing the capital of the country to flow with an accelerated and unnatural velocity into the Treasury? Nothing surely can be more impolitic than this. If we are to have usury laws, they ought to operate alike on every class of borrowers; and, considering the superior attractions which the facility of repossessing the principal gives to the investment of capital in the funds, the rate of interest at which Government should be allowed to borrow, should be less than the rate at which private individuals might borrow.

We trust, however, that we have said enough to show the inexpediency and the pernicious tendency of all such regulations. If a landlord is to be allowed to take the highest rent he can get offered for his land—a farmer the highest price for his raw produce—a manufacturer for his goods—why should a capitalist be restricted and fettered in the employment of his stock? Every principle of natural justice, and of sound political expediency, is outraged by such a distinction.

The present a particular ly at period for abolishing the Usury Laws. So long as the market rate of interest continued higher than the statutory rate, it cannot be doubted that considerable inconvenience would have resulted from any sudden abolition of the usury laws. It is certain, indeed, that this inconvenience would have been very speedily compensated by the check which the abolition would have given to the traffic in annuities, and by the easier circulation and more advantageous distribution of capital. Now, however, when the market is fallen below the statutory rate of interest, no inconvenience could attend their repeal. It could not lead to any demand for payment of borrowed money, for no individual would require payment of what he could not refer to greater advantage. But, while their repeal would be in no respect disadvantageous, it would enable those who are engaged in employments of more than ordinary hazard, to procure adequate supplies of stock on more favourable terms; and it would also secure us against the risk of future mischief should the market again rise above the legal rate of interest. It is unnecessary, however, to urge the immediate repeal of the usury laws. We think it quite visionary to apprehend any danger from the instant application of a sponge to the whole of the anti-usurious statutes, but it is enough if they are repealed gradually. To avoid exciting any alarm in the minds of the most timid, the rate at which capital may be legally lent at interest might be annually raised one, or one-half per cent., until the rate had been extended to 8 or 10 per cent., when it is clear every restrictive regulation

might be abolished without the possibility of the smallest derangement happening in consequence.

Were the usury laws abolished, it would be proper to frame a statute which should fix the interest to be paid in those cases in which no previous agreement had been made respecting it. But as, in cases of this description, there is very frequently considerable doubt whether it was the intention of the parties at the time the transaction took place, that any interest should be charged; it would be proper to give the borrower the full benefit of this doubt, by fixing the rate payable in such cases at the lowest market rate.

Before concluding we may remark, that, until the Error of laws regulating the rate of profit and the increase of some writers on the subject of a low rate of Interest. capital had been accurately investigated, the great wealth and commercial prosperity of Holland was invariably appealed to as a practical proof of the advantages of a low rate of interest. But Sir Josiah Child, and those who have insisted so much on this example, forget that the lowness of interest in Holland was the necessary effect of the circumstances in which that country was placed,—of the lowness of profits, caused by the oppressiveness of taxation, and the deficient supply of fertile soil, and not of any interference on the part of the Government. Neither was this lowness of interest any advantage, but a positive disadvantage. A country, whose average rate of profit, and consequently of interest, has been reduced considerably below the level of surrounding nations, may, notwithstanding, abound in wealth, and be possessed of an immense capital, but it would be the height of error to suppose, that this reduction of profits and interest could have facilitated their accumulation. Capital cannot be accumulated otherwise than by a saving of income, and wherever incomes are large, and this will always be the case where the rate of profit is comparatively high, there must be a proportionably increased facility of gratifying the prevalent passion for accumulation. The case of Holland, far from contradicting, furnishes a striking example of the truth of this principle. Sir William Temple mentions, that her trade was rather on the decline in 1670; and the large capital of which she was then in possession had been accumulated previously to her wars with Cromwell, and when the rate of profit was much higher than at any subsequent period. Low profits are a certain proof that society has become clogged in its progress. They show, that it is approaching, if it has not already reached, the stationary state, and that, unless measures can be devised for relieving the pressure on the resources of the state, it will be thrown back in the career of improvement, and outstripped by its neighbours. The rate of profit, and the rate of interest, are ordinarily twice as high in the United States as in Great Britain or France, and it is to this that the more rapid advancement of the former in wealth and population is entirely to be ascribed. High profits, it is true, may not, in every instance, be accompanied by a great degree of prosperity; for, a despotic government, or the want of sufficient protection, may paralyse all the efforts of those who are otherwise placed in the most favourable circumstances for the accumulation of wealth. But, if the

Interest
||
Inverness-
shire.

government be equally liberal, and the property be equally well secured, the degrees of national prosperity will be correspondent to the rate of profit. The demand for labour, or which is, in effect, the same thing, the funds for supporting the largest and most valuable portion of society, increase or diminish in exact proportion to the increase or diminution of profits. Wherever they are high, the labourer is well paid, and the society rapidly augments both its population and its riches: on the other hand, wherever they are low, the demand for labour is proportionably reduced, and the progress of society rendered so much the slower.

Instead, therefore, of a low rate of profit, and a low rate of interest, for the one must be always directly as the other, being any proof of the flourishing situation of a country, it is distinctly

and completely the reverse. High profits show that capital may be readily and beneficially invested in the different branches of industry, and wherever this is the case, it will be better for the borrower to pay a high rate of interest than it would be for him to pay a lower rate, in countries where there is less facility of employing his stock with advantage. The borrower who pays 10 or 12 per cent. for capital in the United States, generally makes a more profitable bargain than the English borrower who pays only 4 or 5 per cent. It is obviously not, by the circumstance of the rate of interest payable on loans being absolutely high or low, but by the proportion between that rate and the average rate of profit, that we must determine whether they have been obtained on favourable or unfavourable terms.

(2. s.)

Situation
and extent.

INVERNESS-SHIRE, the most extensive county in Scotland, situated between 56° 40' and 57° 36' north latitude, and between 3° 50' and 5° 50' west from Greenwich, is bounded on the north by the shires of Ross and Cromarty; on the east by Aberdeen, Banff, Moray, and Nairn, and by the Moray Frith; on the south by Perth and Argyle; and on the west by the Atlantic Ocean: It is from 50 to 75 miles in length; in breadth from 30 to 50 miles; and its area is computed to be 3036 square miles, of which the space occupied by lakes has been estimated at 132 miles, and the land at 2904, or 1,858,560 English acres.

Boundaries

The exterior outline of this county is exceedingly irregular. On the north-east, where the county town is situated, a narrow tract runs out between Nairnshire and the Moray Frith; farther to the east, a portion of it is detached and inclosed by the counties of Moray and Banff, Argyleshire penetrates into it from the south-west; and on the west it is indented by lochs Moydart, Aylort, Nevish, Hourn, and other arms of the sea.

Surface.

The surface is still more varied, consisting of ranges of lofty mountains, alternating with deep narrow vallies, the beds of a great many lakes and rivers. The most prominent feature is Glenmore, or the Great Glen, for the most part a mile in breadth, and bounded on either side by precipitous high grounds, which traverses the county from south-west to north-east, dividing it into two nearly equal parts. In this glen, from north to south, are Loch Ness, Loch Oich, and Loch Lochy, which, when united by a canal of about 22 miles (see CALEDONIAN CANAL in this Supplement), will form a line of inland navigation between the east and west seas, or from the Moray Frith, on the north-east, to Linnhe Loch, an arm of the Atlantic, on the south-west, a distance of about 60 miles, for frigates of 32 guns, and vessels of 600 tons. Loch Ness is remarkable for never freezing, a circumstance attributed to its great depth, and for its waters having been violently agitated during the great earthquake at Lisbon in November 1755. On each side of this valley there is a number of glens and straths, separated by mountainous ridges: with lakes which receive the waters from the high grounds, and discharge them by out-

lets, partly into the lakes in the central valley, and partly, by a more direct course, into the arms of the Atlantic on the west, or by rivers which flow from this county into the counties on the east, and thence into the German Ocean.

The western side, or the country between the great valley and the Atlantic, from Argyleshire on the south to Ross-shire on the north, a distance of about 70 miles, is the most wild and mountainous tract of Inverness-shire, and is therefore known by the name of the *Rough Bounds*; yet before reaching the sea coast, the general elevation is somewhat diminished. In this tract, beginning at the south, the principal divisions are Moydart, Arassig, Morrer, Knoydart, and Glenelg, which contain a variety of glens or vallies, among which are Glengary, Glen Moriston, Glen Urquhart, and Strathglass. The most considerable lakes in this quarter are Loch Eil, Lochs Loch Shiel, Loch Arkeg, Loch Gary, and Loch Maddy. Lochan Uain, in the parish of Kilmorack, about 40 miles west from Beauly, is said to have been known to remain frozen all the year through. On the east side of the valley lies the extensive district of Badenoch; at its southern termination is Lochaber; and at its northern the Aird, the most fertile part of the county. These divisions also comprise a great many glens, lakes, and rivers, extensive woodlands, and not a little productive land. The principal vallies here are Glenroy, noted for its parallel roads, which it is now agreed must have been formed by the gradual subsidence of the waters, and not by the hand of man, Strathspey, Stratherrick, Strathearn, and Strathnairn. Treig, Erich partly in Perthshire, Laggan, Inch, and Moy, are the names of the most considerable of the lochs in this quarter; and here the Spey, the Findhorn, and the Nairn, and a number of smaller streams, have their source.

The general aspect of Inverness-shire may be further conceived; when it is stated that two-thirds of the surface is covered with heath; only a fortieth part corn land; and that the corn land, woodlands, and green pastures, together, do not exceed eight acres in an hundred. In many large tracts, heath prevails to such a degree that, for twelve or thirteen miles, scarcely any verdure is to be seen, except

Moors and
Mountains.

Inverness-shire.

where a solitary rivulet has occasionally overflowed its banks. On the south of Badenoch, there is a flat of deep moss, supposed to be the most extensive in Britain, in which a great number of small lakes are interspersed, some of them containing wooded isles, where the deer, from the inaccessible nature of the ground, find shelter from their pursuers. But the far greater part of the county is occupied with mountains. Ben-Nevis, 4380 feet high, stands on the south-west, a little to the east of the Caledonian Canal; Meal Fournounie, on the west of Loch Ness, is more than 3000 feet high; and Cairngorm, partly in Banffshire, upwards of 4000. It has been remarked, as a singular circumstance, that several of the hills, which are covered with heath on the sides, are green on the summit, and produce valuable pasturage. The productive land lies chiefly on the sea coast, and along the banks of the lakes and rivers; much of it in the latter situation is alluvial and fertile: there is also clay in a few places; but the prevailing soil is sand, or a sandy loam, well adapted to the growth of barley, potatoes, turnips, and other green crops.

Productive Land.

Rivers.

The principal rivers of Inverness-shire are the *Spey*, which rises from a loch of that name a little to the east of the Great Valley, and flowing in a course from south-west to north-east for about 96 miles, falls into the sea, about eight miles east of Elgin, in Morayshire, carrying with it the waters of 1300 square miles; the *Ness*, which issues from Loch Ness, and, flowing through the town of Inverness, falls into the Moray Frith, after a course of six miles; the *Lochy* issues from Loch Lochy, and has a course of ten miles westward, till it falls into Loch Eil, near Fort-William; soon after it leaves its parent lake it is joined, from the east, by the *Spean*, which is remarkable for being crossed by a bridge, two of the arches of which are 95 feet high; and the *Beauly*, which has its source in the north-west, and carries the united waters of the *Glass*, and other two rivulets, into the Frith of the same name. The *Finlhorn* and *Nairn* on the east, and the *Garry* and the *Morrison* on the west, are smaller streams. The *Foyers*, which flows into Loch Ness from the south, is remarkable for its celebrated falls, one of which, according to Dr Garnet, is 70 feet, and the other half a mile lower, 212. There are cascades not inferior to these in the parish of Kilmorack, on the waters which unite to form the *Beauly*, and at Loch Leven head, in the southern quarter; near which last place there are also some remarkable caverns.

Minerals.

Granite, limestone, slate, marble, brick-clay abound in many parts of Inverness-shire; lead has been discovered in Ben-Nevis, and at three other places in that neighbourhood, and also at Glengary, but none of it is wrought. A vein of plumbago has been found in Glengary. A great part of the mountain Ben-Nevis is composed of beautiful porphyry. There is no coal, and for want of it much of the limestone is of little value.

Woods.

From the trees found in great numbers, and some of them of a remarkable size, in all the mooses, there is reason to believe that this country was, at an early period, almost covered with wood; and at present there is a greater space covered with natural pines here than in all the rest of Britain. In Strathspey,

it is said that three tiers of stacks have been found, directly above one another, in a moss, from which it is inferred that the deepest must have come to maturity, and been destroyed, before the one next above it was formed. In the same district, there are about 15,000 acres of natural firs, besides 7000 of planted firs and larches; and the natural woods on Loch Arkeg, in Glengary, Glenmoriston, Strathglass, Glen Strathfarrer, and at the head of Loch Shiel, are also very extensive. Full grown trees of ash, lime, beech, oak, plane, and mountain-ash, are found at Castle Grant, Culloden, and Belladrum, in the northern quarter of the county; but in most other places, the woods are in the state of coppice. The birch is in great abundance on the sides of Loch Ness, Loch Laggan, about Rothiemurchus, and in the vale of Urquhart. Part of the great Caledonian Forest extends for several miles near the boundary of this county with Perthshire. Considerable tracts have been planted, chiefly with firs and larches, particularly in the north-east, where the county town is situated, in Badenoch, and on Loch Eil.

There are several fishing villages on the east coast, yet the sea-fishery is not prosecuted to a great extent, partly owing, it is alleged, to the regulations of the Salt Laws. But the arms of the sea, and the numerous lakes and rivers, afford an abundant supply of fish. The herring occasionally visits Loch Eil; salmon yield a considerable rent on the rivers *Lochy*, *Beauly*, and *Ness*, and are found also in the *Morrer*, in Loch Insh in Badenoch, and at Invermoriston. Char is caught in several of the lochs, and flounders and sprats in the *Beauly*. The moors and woodlands are plentifully stocked with game,—red and roe deer, the Alpine and common hare, black game and ptarmigan, grouse, partridges, &c.; and pheasants have been lately introduced. Foxes and wild cats are still numerous, and in the lakes and rivers, otters. There are also eagles, hawks, and owls; and a multitude of water fowls, particularly swans, resort to Loch Insh, and the other lakes of Badenoch.

The territory of Inverness-shire is divided into estates of great extent, and, in proportion to the rental of the county, of great value. In 1804 more than the half, if we may judge from the old valuation, belonged to seven proprietors, and as much more was held by other six, as made the possessions of these thirteen individuals equal to more than two-thirds of the whole, each of them at a medium must, therefore, have contained about 100,000 acres. In 1811, the number of estates was seventy-seven, of which fifty-seven were below L.500 Scots of valuation. The greatest proprietors are the Duke of Gordon, the Earl of Moray, Lord Macdonald, Lord Cawdor, Macleod, Fraser of Lovat, Sir James Grant, Grant of Rothiemurchus, Mackintosh, Cameron of Lochell, Macnair, Macpherson, Chisholm, Macdonell of Glengary, Macdonald of Clanranald, Baillie of Duff, and Forbes of Culloden, most of whom have seats in the county. The valuation taken in 1601 is L.78,188, 9s. Scots, and in 1811, the real rent of the lands was L.195,843, 15s. Sterling, and of the houses, L.9235, 2s. Sterling. The old valuation of the whole of Scotland,

as fixed about the middle of last century, and which is still the rule by which county assessments are imposed, is to the actual rent of the lands alone in 1811, as L.1 Scots is to L.2.675 Sterling; whereas in this county, rents have risen in so much greater a proportion than in the rest of Scotland, chiefly perhaps owing to the introduction of sheep-farming; that its valuation is to its actual rent only as L.1 Scots is to L.2.675 Sterling; and it is worthy of remark, that this rise cannot be ascribed in any considerable degree to the outlay of capital by proprietors, in building or otherwise, as in most other parts of Scotland.

Rural Eco-
noty.

Of the occupiers of the land,—tacksmen, small tenants, and cottars—of the size of the farms, and of the rural economy of the county generally, we have little to say in addition to what we have already offered under the Highland counties of Scotland in the preceding part of this Supplement. Small spots of corn-land contiguous to the hamlets, of which the alternate ridges or lands belong to different cultivators, who used to interchange their allotments once a year, and more recently, only once in three years; a larger space of *outfield* beyond this, part of which is constantly cropped till it is exhausted, and then left to nature, when another part, which had been treated in the same manner, but which has been somewhat restored in the mean while by the folding of cattle, takes its place; and beyond this outfield, separated from the higher grounds by a *head dike*, large tracts of common pasture;—these, with their miserable huts, their irregular and always inefficient labour, their indolence, their poverty, present a striking picture of what must have been the condition of the great body of the people of Scotland during the feudal ages; and which is not now, as it was then, somewhat relieved by hospitality and protection on the one side, and respect, gratitude, and attachment, on the other.

This system, indeed, has been gradually approaching to its termination for the last thirty years, and in some parts of Inverness-shire it exists no longer in its original form. The change has been chiefly effected by the introduction of sheep, which has occasioned so many complaints, and probably much real suffering for a time to many individuals; but which is likely in the end to be most advantageous to the public at large. With respect to its effect on population, one main topic of declamation, it has not been such as its opponents allege; for the population of Inverness-shire, any more than of the Highlands in general, has not diminished. On the contrary, its increase in this county, from 1755 to 1811, has been much greater than in Haddingtonshire and the other merely agricultural districts of Scotland. Within that period, it has increased from 64,656 to 78,336, or upwards of 21 *per cent.* while that of all Scotland has been no more than 44 *per cent.*; and it is well known that the far greater part of this apparently general increase has been occasioned by the extension of manufactures and commerce, and is chiefly confined to a few districts.

Trade

The principal exports are cattle, sheep, wool, timber, and slates. The corn grown in the county, chiefly bear or big, and oats, and only on the east

Inverness-shire

coast wheat, is all consumed within itself, much of the bear in illicit distillation; as well as all the potatoes, the most important article of food for the greater part of the year; and the products of the dairy. It imports coals, lime, flour, oatmeal, groceries, and other articles of domestic consumption. The manufactures are, bagging from hemp, thread, kelp to tures, a considerable extent on the west coast, with some tiles and bricks. There are also tan-works, breweries, bleachfields, and an iron-foundry; and some attempts have been made at different periods to carry on branches of the woollen manufacture.

Inverness, the capital of the Highlands, a royal burgh, and the only town of any extent in the county, is situated on both sides of the river Ness, at its entrance into the Moray Frith. It is a place of great antiquity, but it is only since the middle of the last century that it has made regular advances to its present prosperity. Nearly all the trade and manufactures of the county are carried on here, and it is favourably situated for becoming a place of general resort for the northern counties, of which it is considered the metropolis. The population, in 1811, was 11,353. From the west sea, a few vessels come up to Fort-William, from which the exports are wool, skins, herrings, kelp, and slates. The most considerable village is Maryburgh, or Gordonsburgh, near Fort-William. Grantown is a neatly built village on the great road along the Spey, which, under the auspices of Sir James Grant, the proprietor, has made considerable progress. It contains a town-house and prison, with a well endowed school, and a few years ago a factory was begun for carding and spinning wool, and for making blankets and woollen cloths. Fairs are held for the sale of cattle, sheep, and wool, at Fort-William, Beaully, Grantown, and Kingussie, and four in the year in Inverness, where there is also a well supplied market every Tuesday and Friday. An easy communication is now formed throughout the greater part of the county by means of the roads made under the direction of the *Parliamentary Commissioners for Highland Roads and Bridges*, half the expense of which is borne by the county, and the other half is granted by Parliament.

Roads

Among the antiquities of Inverness-shire, which we can only notice generally, are the circles of stones ascribed to the Druids, which are found in many parts of the county, particularly at Corrimony in its northern quarter; two artificial mounds in the parish of Petty, supposed to have been places for administering justice; round buildings, called Picts' Houses, in Glenelg, and other parts; forts, built without mortar, one of which, called Castle Spynie, two miles east from the church of Beaully, incloses a circle of 54 yards, and another in the parish of Laggan, stands on a rock, 100 yards in perpendicular height; vitrified forts on the hill of Craig Phadric, about two miles from Inverness, Dundhairdghall in Glen Nevis, and Dun Thion near the river Beaully; and a variety of castles, of which Inverlochy Castle, a building of great extent, and unknown antiquity, on the banks of the Lochy near Fort-William, is, perhaps, the most remarkable. On a hill near Inverness, called the Castle Hill, stood

Antiquities

Inverness-shire.

the castle of the Thane of Cawdor, where Macbeth is said to have murdered Duncan. It was razed by Malcolm Kenmore, who removed the town to the northward, where it now stands, granted its first charter, and built a fortress on the site of the old town, which was repaired in 1715, and finally demolished in 1765. Cromwell erected a citadel at the mouth of the river Ness, which was demolished by Charles II.

Forts.

The chain of forts along the line of the Caledonian Canal has been already noticed. (See INVERNESS-SHIRE in the *Encyclopædia*.) *Fort-George* is a regular fortress, mounting 80 guns, with barracks for 3000 men, which was begun in 1747, and completed in 20 years, at an expence of about L.160,000. It is situated 11 miles eastward from Inverness, upon a neck of land on the Moray Frith, opposite to Fort-rose in Ross-shire. *Fort-Augustus*, also a regular fortification, though a place of no great strength, with four bastions and barracks for 400 men, is situated at the west end of Loch Ness, nearly midway between the east and west seas. It was first built in 1730 at some distance from Loch Ness, but having been demolished by the rebels in 1745, it was afterwards rebuilt nearer the lake. *Fort-William*, built in the reign of William III., is situated on a navigable arm of the sea, called Loch Eil, at the southwestern termination of the great valley. Part of it is now in ruins, but it is still occupied by a company

of invalids. On Culloden Moor, a level heath to the eastward of Inverness, on the 16th April 1746, was fought the battle which put an end to the rebellion of 1745; the greater part of this heath is now covered with plantations.

Inverness-shire.

Inverness-shire contains twenty-eight entire parishes, and shares other four with the counties of Argyle, Nairn, and Moray. Of these, twenty are on the mainland, and the remainder in its islands. Some of the parishes on the mainland, as well as in the islands, would form a square of 20 miles each. Kilmalie and Kilmorack are still larger, extending in length about 60 miles, and in breadth almost 30. Many of the inhabitants are Roman Catholics, particularly in the districts of Moydart, Arasaig, Morrer, and Knoydart, on the west side. The county sends one member to Parliament, and the town of Inverness, along with Forres, Nairn, and Fortrose, choose one for the burghs. The Sheriff holds courts at four places, two of which, Inverness and Fort-William, are for the mainland, and two more for the isles in Skye and Long Island. The population of the whole shire in 1800 and 1811 is given in the annexed table.—(See the *Statistical Account of Scotland*, and Playfair's *Description of Scotland*; Robertson's *Survey of Inverness-shire*; *The Beauties of Scotland*, Vol. V., and the *General Report of Scotland*.) IODINE. See CHEMISTRY, in this Supplement, p. 15.

JOINERY

Joinery.

Is one of the useful arts which contributes most materially to the comfort and convenience of man. As the arts of joinery and carpentry are often followed by the same individual, it appears, at first view, natural to conclude, that the same principles are common to both these arts. But a closer examination of their objects leads us to a different conclusion.

Carpentry
defined.

The art of Carpentry is directed almost wholly to the support of weight or pressure; and, therefore, its principles must be found in the mechanical sciences. In a building, it includes all the rough timber-work necessary for support, division, or connection; and its proper object is to give firmness and stability. See the Article CARPENTRY in this Supplement.

Joinery defined.

The art of Joinery has for its object, the addition in a building of all the fixed wood-work necessary for convenience or ornament. It is the *Intestinum opus* of Vitruvius; and the *Ménagerie de bâtimens* of the French.

The joiner's works are, many of them, of a complicated nature, and require to be executed in an expensive material; therefore joinery requires much skill in that part of geometrical science which treats of the projection, and description of lines, surfaces, and solids, as well as an intimate knowledge of the structure and nature of wood.

It may also be remarked, that the rough labour of the carpenter renders him, in some degree, unfit to produce that kind of accurate and neat workmanship which is expected from a modern joiner.

Progress of
Joinery in
England.

In early times, very little that resembles modern joinery was known; every part was rude, and joined in the most artless manner. The first dawnings of the art appear in the thrones, stalls, pulpits, and screens, of our cathedrals and churches; but, even in these, it is of the most simple kind, and is indebted to the carver for every thing that is worthy of regard. Whether, in these monuments, the carver and the joiner had been one and the same person, we cannot now determine, though we imagine, from the mode of joining in some of them, that this was the case.

During several centuries joinery seems to have been gradually improving, but nothing appears to have been written on the art before 1677, when Mr Joseph Moxon, a Fellow of the Royal Society, published a work, entitled *Mechanick Exercises, or the Doctrine of Handynworks*. In this work the tools, and common operations in joinery, are described, with a collection of the terms then in use. It must have been a valuable work at that time, but to a master in the art it would convey little if any thing that was new. Sash-windows were introduced into England some time before the date of Moxon's work, but he has not noticed them. According to the observations of Dr Thomson, this important im-

provement has not yet found its way into Sweden. (Travels in Sweden, p. 8.)

Joinery.

About the beginning of the last century, several works of a most interesting kind made their appearance. Forms began to be introduced in architecture which could not be executed, at a moderate expense, without the aid of new principles, and these principles were discovered and published by practical joiners. As might naturally be expected, these authors had but confused notions, with a scanty portion of geometrical knowledge; and, accordingly, their descriptions are often obscure, and sometimes erroneous.

The hand-rails of stairs offered many difficulties, and an imperfect attempt to remove them was first made by Halfpenny, in his *Art of Sound Building*, published in 1725. Price, the author of the *British Carpenter*, published in 1733, was more successful, and his remarks show a considerable degree of knowledge of the true nature and object of his researches.

The publication of Price's work must have produced a considerable sensation among joiners, for it was soon followed by many other works of different degrees of merit. Of these the works of Langley and Pain were the most popular.

The establishment of the principles of joinery, on the sound basis of geometrical science, was reserved for Nicholson. In his *Carpenters' Guide, and Carpenter and Joiners' Assistant*, published in 1792, he has made some most valuable corrections and additions to the labours of his predecessors.

Corresponding improvements were also made in the practice of joinery, for which we are much indebted to the late Mr James Wyatt. This celebrated architect kept together some of the best workmen in London, who were looked up to with a degree of emulation by young men, which had a beneficial effect on the progress of joinery. But the art is still far short of perfection. We conceive that many of those operations, on which the soundness of work chiefly depends, might be done with greater exactness, and less labour, by means of tools contrived for these purposes. The truth and certainty which have been introduced in block-making, is sufficient to encourage some one to extend the same manner of mortising to joinery. (See BLOCK-MACHINERY in this Supplement.)

The principles of joinery were cultivated in France by a very different class of writers. In the extensive work of Frezier, entitled *Coupe des Pierres et des Bois*, 3 Vols. 4to. 1739, all the leading principles are given and explained with tedious minuteness; offering a striking contrast to the brevity of our English writers. The first elementary work on that part of geometrical science, which contains the principles of joinery, appeared in France, in 1795, from the pen of the celebrated Gaspard Monge,

Progress of
Joinery in
France.

JOINERY.

Joinery. who gave it the name of *Geométrie Descriptive*. Much of what has been given as new in English works, had been long known on the Continent; but there does not appear to have been much, if any, assistance derived from these foreign works by any writer prior to Nicholson.

The latest French work which treats of joinery is Rondelet's *L'Art de Bâtir*. It is also the best foreign work on the subject that we have seen; but it is not at all adapted to the state of joinery in England. In practice, the French joiners are very much inferior to our own. Their work is rough, slovenly, and often clumsy, and at the best is confined to external effect. The neatness, soundness, and accuracy, which is common to every part of the works of an English joiner, is scarcely to be found in any part of the works of a French one. The little correspondence, in point of excellence, between their theory and practice, leads us to think that their theoretical knowledge is confined to architects, engineers, &c. instead of being diffused among workmen, as it is in this country.

In cabinet-work the French workmen are certainly superior, at least as far as regards external appearance. But when use, as well as ornament, is to be considered, our own countrymen must as certainly carry away the palm. The appearance of French furniture is much indebted to a superior method of polishing, which is now generally known in this country.* For many purposes, however, copal varnish (such as coachmakers use) is preferable; it is more durable, and bears an excellent polish.

Geometrical knowledge necessary. Geometry is useful in all, and absolutely necessary in some, parts of a joiner's business: but it is absurd to encounter difficulties in execution, and to sacrifice good taste, convenience, economy, and comfort, merely for the purpose of displaying a little skill in that science. It is, however, a common fault, among such architects as are better acquainted with geometrical rules than with the production of visible beauty, to form designs for no other purpose than to create difficulties in the execution.

But, when geometrical science is properly directed, it gives the mind so clear a conception of the thing to be executed, that the most intricate piece of work may be conducted with all the accuracy it requires.

Practice of Joinery. The practice of joinery is best learned by observing the methods of good workmen, and endeavouring to imitate them. But the sooner a workman begins to think for himself the better; he ought always to endeavour to improve on the processes of others; either so as to produce the same effect with less labour, or to produce better work.†

We intend, in this article, to give a plain and simple exposition of the most valuable principles of the art of joinery, which will, we hope, place many

parts of the practice under a new point of view, and ultimately tend to improve them. Joinery.

Cabinet-making, or that part of the art of work- ing in wood which is applied to furniture, has little affinity with joinery, though the same materials and tools be employed in both. Correctness, and strict uniformity, are not so essential in moveables as in the fixed parts of buildings; they are also more under the dominion of fashion, and therefore are not so confined by rules as the parts of buildings. Cabinet-Making.

Cabinet-making offers considerable scope for taste in beautiful forms, and also in the choice and arrangement of coloured woods. It requires considerable knowledge in perspective, and also that the artist should be able to sketch with freedom and precision.

If the cabinet-maker intend to follow the higher departments of his art, it will be necessary to study the different kinds of architecture, in order to make himself acquainted with their peculiarities, so as to impress his works with the same character as the rooms they are to furnish.

In as far as regards materials, and the principles of joining work, the cabinet-maker will find some useful information in the second and third sections of this article. In ornamental composition, he may derive much benefit from Tatham's *Etchings of Ancient Ornamental Architecture*, London, 1799; Percier et Fontaine's *Recueil de Décorations Intérieures comprenant tout ce qui a rapport à l'Ameublement*, Paris, 1812; and, for general information, the *Cabinet Dictionary*, and the *Cabinet-Maker and Upholsterer's Drawing-Book* of Sheraton, may be consulted.

SECT. I.—ON MAKING WORKING DRAWINGS.

1. In this section we propose to lay before the reader the most important part of the principles of describing, on a plane surface, the lines necessary for determining bevells, forming moulds, or any other purpose required in the practice of joinery. The limits, within which such an article as joinery must be confined, in a work like this, will not permit us to enter much into detail on the various points to be illustrated in this section; but we hope, by judicious selection, to place under one point of view the principles that are most useful to the joiner.

Projection of Bodies.

2. A clear idea of the nature of projection is so essential in making working drawings, that, in our endeavours to illustrate it, we cannot proceed from principles too simple. In the first stage of such an inquiry, experiment furnishes at once the most clear and satisfactory evidence, particularly to those who are not familiar with mathematical subjects. Nature of Projection illustrated.

If some small pieces of wood, or pieces of wire,

* The method of making and using the French polish is minutely described in Dr Thomson's *Annals of Philosophy*, Vol. XI. p. 119 and 371.

† Descriptions of the tools, with instructions for using them, may be found in Moxon's work before quoted, and in Nicholson's *Mechanical Exercises*, Taylor, London, 1812.

Joinery. were joined together, so as to represent the form of a solid body, a cube for example, and if this figure were held between the sun and the surface of a plane board, then the shadow of the figure upon the board would be its projection upon that plane. From this simple experiment, it will appear, that the projection of any line placed in the direction of the sun's rays will be a point: the projection of any line parallel to the plane will be of the same length as the line itself, and the projection of any line inclined to the plane will be always shorter than that line.

3. We have supposed the board to be placed at any angle with the direction of the rays of the sun; but, for our present purpose, it is sufficient to consider them to fall perpendicularly upon it; hence it is obvious, that to project a straight line upon a plane, a perpendicular to the plane should be let fall from each end of the line, and the line joining the points where the perpendiculars meet the plane will be the projection required.

When a projection is made upon a horizontal plane, it is usually called a *plan* of the body. When the projection is upon a vertical plane, it may be an *elevation* or a *section* of the body; it is a section when a portion is supposed to be cut off; and the plane of projection is usually parallel to the plane of section.

4. Bodies may be divided into three classes, according to the kinds of surfaces by which they are bounded. The first class, comprehending those which are bounded by plane surfaces, such are cubes, prisms, pyramids, and the like. The second class contains those which are bounded in part by plane surfaces, and the rest by curved surfaces, as cylinders, cones, &c. The third, including those which are bounded by curved surfaces only, as spheres, pheroids, &c.

The projections of the first class of bodies will consist of straight lines; those of the second class, of curved as well as straight lines; and those of the third class, of curved lines only.

Projection
of Lines.

5. Let ABCD, and CDEF, Fig. 1, Plate LXXXVI. be two plane surfaces, connected by a joint at CD, so that while the plane CDEF remains horizontal, the plane ABCD may be placed perpendicular to it, and thus represent a vertical plane. Then, if a line be so placed in space, that *ab* is its projection on the vertical plane, and *a'b'* its projection on the horizontal plane, its projection on any other vertical plane, HGEC, may be determined. This is easily effected, for we have seen, that if a perpendicular be drawn to the plane from each end of the given line, they will give the positions of the ends of the line in the projection (Art. 3). Now, the same thing will be done, by drawing *a'a''* and *b'b''* perpendicular to EC, and setting off the points *a''* and *b''* at the same height above EC respectively, as *a* and *b* are above CD, then the line *a''b''* is the projection required.

The heights may be transferred from one vertical plane to another when they are both supposed to be laid flat, by drawing the line IC, so as to bisect the angle ECD, and if *cb* be parallel to CD, meeting IC in *c*, then a line drawn parallel to EC, from the point *c*, will give the height of the point *b''*, and so may be found the height of any other point.

VOL. V. PART I.

6. In the particular case we have drawn, none of the projections represents the real length of the given line. To obtain this length, draw *a'e* parallel to CD, and with the radius *ab* describe the arc *b'e* cutting *a'e* in *e*; draw *de* perpendicular to CD, cutting the line *cb* in *d*; join *ad*, and it is the length of the given line.

The real lengths of lines frequently are not given, therefore another general method of finding them will be found useful, and which may be stated as follows: the length of an inclined line projected upon a plane is equal to the hypotenuse of a right-angled triangle, of which one side is the projection upon the plane, and the other side is the difference between the perpendicular distances of the extremes of the line from the plane.

7. In Fig. 2, *a'b'cd* represents the horizontal projection, or plan, of a rectangular surface, and the elevation *ab* shows its inclination; and its projection against another vertical plane, making any angle ECD with the former, or plane of elevation, is shown by *a''b''c'd'*. GC being perpendicular to EC, and AC perpendicular to CD, the heights may be transferred by means of arcs of circles described from C as a centre. This is a better method than that by bisecting the angle given in fig. 1; but neither of them so good, in practice, as setting of the heights with the compasses, or with a lath. In our figures it is desirable to show the connection of corresponding parts as much as possible; therefore, the reader will bear in mind that many of the operations we describe may be done with fewer lines when the operator is fully master of his subject.

8. It may be further noticed in this place, that when a point is to be determined in one line, by the intersection of another, the lines should cross each other as nearly at right angles as possible; for, when the intersecting lines cross very obliquely, a point cannot be determined with any tolerable degree of accuracy.

9. A curved line can seldom be projected by any other means than by finding a number of points through which the projected line must be drawn, or finding a series of tangents to the section. In giving an example of the projection of a body bounded by a curved surface, we shall select a case of frequent occurrence in practice, referring to the *Geometrie Descriptive* of Monge, for more general methods.

Let ABC be part of the plan of the base of a solid, fig. 3, and FED its end elevation; the upper side of the solid being bounded by the curved surface FD. This solid is supposed to be cut at AB by a plane perpendicular to the base, and our intention is to show the form of the section.

Draw EH parallel to BA, and GHE will represent the plane upon which the section is to be projected. Set off any convenient number of points, 1, 2, 3, 4, &c. in the given curve FD, from each of these points draw a line perpendicular to ED, to meet BA; and from the points in BA, thus determined, erect perpendiculars, which will cut HE at right angles. Make GH equal to FE, and set off the points 1, 2, 3, &c. in GHE at the same distances respectively from HE, as the corresponding points 1, 2, 3, &c. in FED are from the line ED. A curve

Projection
of Curved
Lines.

Join

being drawn through the points E, 1, 2, 3, 4, 5, G will complete the section. In large works the joiner will often find it useful to put nails in the points, and to bend a regular lath against the nails; with the assistance of the lath the curve may be drawn with more regularity.*

If the curve FD were very irregular, or a mixed line of straight parts and curved ones, the same method would determine the section; all the caution required is, that a sufficient number of points should be fixed upon in the given curve; and upon the proper selection of these points much of the accuracy of the section will depend.

The angle ribs of groined ceilings, the angle ribs for coved ceilings, or brackets for large cornices, and the angle cantilevers for balconies or other works of a similar kind, are found by this method. If FD be the cross rib of a groin, then GE will be the form of the corresponding angle rib. Also, if the angle of a room be represented by LAC, and FD be the cove for the ceiling, then GE will be the proper angle rib for such a cove.

In some cases, the section may be determined by means of the properties of the given curve, when the nature of that curve is known. Thus the oblique section of a cylinder is an ellipse, and the sections of a cone are certain figures depending on the direction of the plane of section (see CONIC SECTIONS, in the *Encyclopædia*); but if an architect were confined to the use of geometrical curves, there would be small scope, indeed, for a display of taste in his art, therefore the joiner must generally have recourse to the simple method we have described.

10. The section of a body may often be drawn by a more simple and direct process; and yet where the principle is still the same. Thus, the section of the half cylinder ACB, in fig. 4, being compared with the process in fig. 3, will be found to be the same in every respect, excepting in the position of the parts of the figure. In fig. 4, ACB is the end or plan of the cylinder, and DE the inclination of the plane by which it is cut. Let the ordinates a 1, b 2, &c. in the plan, be drawn perpendicular to AB, and continued till they cut the inclined line DE. Also, draw the ordinates a' 1', b' 2', &c. perpendicular to the line DE, and make the distances a' 1', b' 2', &c. respectively equal to the corresponding distances a 1, b 2, &c. upon the plan. Through the points E, 1', 2', &c. draw the curve DFE.

As the curve DFE is an ellipse, when ABC is a circle, in that case it will be better to draw an ellipse with a trammel, or any other machine that produces the curve by a continued motion. (See ELLIPTOGRAPH in this Supplement.) DE is the transverse, and Fc' the semi-conjugate axis of the ellipse.

The most important application of the case, in fig. 4, is to the hand-railing of a staircase, with a curvilinear well-hole, or opening down the middle. For, if Ae, or aB, show the breadth of the rail, Ac C a B

would be its plan; and De' F a' E the form of a mould, commonly called a face mould, for cutting out the rail by, when DE is the inclination of the plank. We cannot, however, proceed directly to the subject of stair-rails, without considering the developement of the surfaces of bodies.

Developement of Surfaces.

11. To develop the surface of a solid is to draw, To develop
on some plane surface, a form that would cover it. a Pyramid.
If this form were drawn upon paper, and the paper were cut to it, the paper, so cut, ought to cover exactly the surface of the solid. Now, in joinery, it is often required that a mould should apply to a curved surface; and, therefore, the developement of that surface upon a flexible material gives the form of the mould.

The covering of a square pyramid may be found by erecting a perpendicular from the middle of one of the sides of its base, as from a in the side AB, fig. 5. Upon this perpendicular set off a C equal to the slant height of the pyramid; then, with the radius AC and centre C describe the arc A3, and set off the distance AB three times upon the arc. Join the points C3, C2, C1, CA, and CB, and draw the lines 32, 21, 1A, which determine the covering required.

It is obvious that we could develop a pyramid of which the base might have any number of sides, by the same method; and that a near approximation to the developement of a right cone might be effected by the same means, which, in fact, is the means usually employed. But the following method of spreading out the surface of a cone will be found more correct.

12. Let ABC, fig. 6, be an elevation of a cone, To develop
and ADB half the plan of its base. With the radius a Cone
AC describe the arc AE, which will be the line bounding the developement; and, to find the length of the arc, or rather the angle containing it, multiply 360 by the radius Aa of the base, and divide the product by the slant height AC of the cone; the quotient will be the number of degrees in the arc AE, when the surface ACE exactly covers the whole cone. Thus, let Aa be 12 feet, and AC 40 feet; then $\frac{360 \times 12}{40} = 108$ degrees, and making ACE an angle of 108 degrees, we have the sector ACE that would cover the cone.

This applies to the soffits of windows, where they are enlarged towards the inside, to admit light more freely than square recesses would do. If ab be the width of the soffit, draw cb parallel to AB, and from the centre C describe the arc cd . Then half the developement AEdc will be the mould for the soffit; or the form of a veneer that would cover it.

13. The developement of a cylinder is also of use To develop
in forming the moulds for soffits, but is still more a Cylinder.
useful in the construction of stairs; and, as we are

* A simple and convenient instrument for this purpose is described in the *Transactions of the Society of Arts*, for 1817, Vol. XXXV. p. 109.

Joinery. obliged to consider it as a prism with numerous sides, it is obvious that any other body of a like kind may be developed by the same means.

Let ACB, fig. 7, be the plan of half a cylinder, and A'E its height. Divide the curve ACB into any convenient number of equal parts, and let these parts be set off from C to A, and from C to B'. When the curve is a semicircle, divide the diameter AB into the proposed number of parts, and make aD equal to $\frac{3}{4}$ ths of the radius. From D through the points A and B, draw the lines DA', DB', then A'B' is nearly equal to the curve ACB stretched out; and, by drawing a line from D through each of the divisions in AB, the line A'B' will be divided into the same number of equal parts.

In either case, erect a perpendicular from each point of division, and EA'B'F will be the developement of the surface.

If we suppose A'B' to be divided into the number of steps, that would be necessary to ascend from B to A, in a circular staircase, the developement of the ends of these steps may be drawn as in the upper part of the figure. The projection G of the cylinder, with the lines of the developement drawn upon it, and the ends of the steps, shows the waving line formed by the nosings of the steps, and consequently by the hand-rail of a circular staircase.

When a part of a cylinder is cut off by a plane, the line of section will be a curved line upon the developement, as is shown in the lower part of the developement, fig. 7. The faint lines show the manner of finding the edge of the covering, and is the same as finding a mould for a soffit formed by an arch cutting obliquely into a straight wall.

To develop an Oblique Cone. 14. In an oblique cone, the lines drawn on its surface, from its base to the vertex, would be of different lengths, and as those lengths are not shown by the plan, or elevation, they may be had by means of the principle stated in art. 6.

Let ABC, fig. 8, be the given cone, and AEB a plan of half its base; to find the developement, produce AB, and from the vertex, C, let fall the perpendicular CD. Divide the circumference of the base into any number of equal parts, and from each point of division describe an arc from D, as a centre, to cut the line AB at 1, 2, 3, &c. From C, as a centre, describe the arcs AA', 11, 22, &c. and with a radius equal to one of the divisions of the circumference of the base, and the centre B cross the arc 55, which determines the point 5 in the developement, with the same radius, and the point 5, as a centre cross the arc 44, and so on for the remainder of the arcs. Join A'C, and draw a curve line through the points A', 1, 2, &c. which gives the covering for half an oblique cone.

If the cone be cut by a plane, ab , parallel to the base, the surface Bba'A' will be the covering of a soffit for a conical arch cutting obliquely into a straight wall.

To find the covering of a Soffit. 15. As it often happens that there is not a sufficient space between the head of a door, or a window,

and the cornice of the ceiling to admit of the same bevel being preserved at the crown or top, as at the sides of the window, in such cases the soffit is made level at the crown, or with such an inclination only as will prevent the architrave cutting into the cornice of the room.

Let ABCD be the plan of the space to be covered with a soffit, fig. 9, ED the arch of half the opening, which is in its proper position when set perpendicularly over the line CD; and let Fc be the height of the arch over AB. Produce AC and BD to meet at G; set off cm equal to cF , and $3n$ equal to $3E$; then draw a line through the points mn , which will give the inclination of the soffit at the highest part of it. Divide the arch ED into any number of equal parts (in our example we have only divided it into three parts), and from each point of division let fall a perpendicular to CD, meeting the line CD in the points 1, 2. Through these points draw the lines Ga, Gb, cutting the line AB in the points ab , and from each point erect a perpendicular to AB. Set off, on $3n$, the heights of the points in the curve ED, and divide the line mc in the same proportion as $n3$, which will give the corresponding heights for the arch FD, and through the points thus found the arch FD should be drawn.

Make Go perpendicular to GE cutting a line passing through the points m, n , in o , and draw lines through the corresponding points of division in the lines $mc, n3$, so that Go may be divided in the same proportion as $n3$. Draw Gp perpendicular to GD, and equal to Go, and set off upon it the same distances as are upon Go. Then, with a radius G1, and the first division on Gp, as a centre, describe an arc at s , and with a radius equal to one of the divisions of the arc ED and D as a centre, cross the arc s , which gives one point. Also, with a radius G2, and the second division on Gp, as a centre, make an arc at t , which, being crossed by an arc described with a radius, equal to one of the divisions of the arc ED, and s as a centre, determines another point in the edge of the covering. Proceed in the same manner till half the developement of one edge be completed; the other edge will be obtained by drawing lines through the points s, t, u , from the corresponding points in Gp, and making sw equal to $a1$; tr equal to $b2$, &c.

As both sides are the same, the soffit mould for one side requires only to be reversed for the other side. If the soffit be level at the crown, the process may be rendered shorter; but, where it is possible to get space for a slight inclination, the appearance of the soffit is always materially improved.

If the plan of the wall be circular, find the developement of the arc ED as before, and transfer the distances from CD of the points in the curved wall, to the corresponding lines in the developement, in the same manner as was done to find the edge Baccy.

16. The developement of a sphere, or globe, can be effected only by an approximate process, as it is impossible to apply a plane surface so as to touch more than one point at a time; but various methods

Joinery. may be employed, which are useful in forming spherical surfaces.

A sphere may be divided into numerous zones, the surface of each zone may be considered as that of the frustum of a cone, and developed in the same manner as has been described for a portion of a cone in art. 12. The upper part of fig. 10 shows half a sphere developed in this manner; and when it is divided into very narrow zones, the covering found by this process has some advantages, in practice, that are peculiar to it.

17. The surface of a sphere may also be developed by inscribing it in a cylinder, LNMO, fig. 10, and considering a small portion, or gore, ABD, to coincide with the surface of the cylinder. Then, if the portion ABD, considered as part of a cylinder, be developed by the process described in art. 13, one gore, ABZ, will be obtained, and by dividing the circumference of the sphere into any number of equal parts, and making AB equal to one of these parts, the same mould will serve for the whole of the sphere.

Another method of developing a sphere consists in supposing it to be a polyhedral, or many-sided figure, but this method has no advantage over the preceding ones, while it has the inaccuracies of both of them.

In lining and boarding domes, the position of the ribs to which the boards are to be fixed will determine the method of development that ought to be adopted; but the form of the veneers for a spherical surface may be determined by either method.

To determine the Angle formed by two Inclined Planes.

To find the Angle of Planes inclined to one another.

18. The angle made by two planes which cut one another, is the angle contained by two straight lines drawn from any, the same, point in the line of their common section, at right angles to that line; the one in the one plane, and the other in the other.* This angle is the same as that which the joiner takes with his bevel, the bevel being always applied so that its legs are square from the arris, or common section of the planes.

If two lines, AB and CD, be drawn upon a piece of pasteboard, at right angles to one another, crossing at the point E, and the pasteboard be cut half through, according to the line AB, so that it may turn upon that line as a joint; then, to whatever angle, CED, fig. 11, the parts may be turned, the lines EC, and ED, will be always in the same plane. Also, a line FD, drawn from any point D, in the line ED, to any point, F, in the line EC, will be always in the same plane. From these self-evident properties of planes, it is easy to determine the angle formed by any two planes, when two projections, or one projection and the development of the surfaces, are given.

19. Let ABC, fig. 12, be the plan of part of a

pyramid, and BD the elevation of the arris, or line formed by the common section of the planes in respect to the line EB; EB being the projection of that arris upon the plan.

Draw AC perpendicular to EB, cutting it in any point E, and from E draw EF perpendicular to DB. With the radius EF, and centre E, cross EB in f; and join Af and fC, then the angle AfC is the angle formed by the planes of the pyramid.

The angle may be constructed when the plan and elevation of any two lines drawn in the planes, so as to intersect in the arris, are given, but as these projections are not often given in drawings of joiners' work, we have inserted the preceding, though it be a less general method.†

The backing, or angle for the back of hip-rafters in carpentry, and of hipped sky-lights, is found in this manner; ABC being, in that case, supposed to be the plan of an angle of the roof or sky-light, and DB the inclination of the hip-rafter.

20. To show how the angle formed by two planes may be found when the plan and development are given, let it be required to find the angle contained by the two faces of a square pyramid, fig. 5.

Draw FB perpendicular to AC, and with the radius BF, and centre B, describe the arc FG. Then, with the radius DB, and centre F, cross the former arc in G, join BG, and FBG is the angle formed by two, the inclined faces of the pyramid.

Raking Mouldings.

21. When an inclined, or raking moulding, is intended to join with a level moulding, at either an exterior or an interior angle, the form of the level moulding being given, it is necessary that the form of the inclined moulding should be determined, so that the corresponding parts of the surfaces of the two mouldings should meet in the same plane; this plane being the plane of the mitre. It may be otherwise expressed, by saying, that the mouldings should mitre truly together.

If the angle be a right angle, the method of finding the form of the inclined moulding is very easy; and as it is not very difficult for any other angle, it may perhaps be best to give a general method, and, to illustrate it by examples of common occurrence.

General Method of Describing a Raking Moulding, when the Angle and the Rake, or Inclination of the Moulding, is given.

Let ABC, fig. 13, be the plan of the angle of a body, which is to have a level moulding on the side AB; and this level moulding is to mitre with an inclined moulding on the side BC. Also, let CBD be the angle the inclined moulding makes with a level or horizontal line BC.

Produce AB, and draw Cb perpendicular to AB; also make DC perpendicular to BC, and dC perpen-

* This is the definition given by Professor Playfair, in his *Elements of Geometry*, and is better suited to our purpose than Euclid's definition.

† On this subject, the reader may consult Monge's *Géométrie Descriptive*, Art. 19 et 20, par. 23 and 24, 4th edition, Paris, 1820.

JOINERY.

Joinery. dicular to bC . Set off Cd equal to CD , and join bd ; then the inclined moulding must be drawn on lines parallel to bd .

Let 1, 2, 3, 4, &c. be any number of points in the given section of the level moulding; from each of these points draw a line parallel to bd ; and draw AG perpendicular to bd . Set off the points 1', 2', 3', 4', &c. at the same distances, respectively, from the line AG , as the corresponding points 1, 2, 3, 4, &c. are from the line AB ; and through the points 1', 2', 3', &c. draw the moulding. The moulding thus found will mitre with the given one, also supposing the inclined moulding to be given, the level one may be found in like manner.

If the angle ABC be less than a right angle, the whole process remains the same; but when it is a right angle, BD coincides with bd ; and the method of describing the moulding becomes the same as that usually given; as it does not then require the preparatory steps which are necessary when the angle is any other than a right angle.

For Pediments

22. It is in pediments, chiefly, that the method of forming raking mouldings is of use. Fig. 11 represents part of a pediment; AB is that part of the level moulding which mitres with the inclined moulding; all that part of the cornice below B , being continued along the front, the lower members of the raking cornice stop upon it, and, therefore, do not require to be traced from the other.

In that part of the cornice marked AB , set off a sufficient number of points; and from each of these points draw a line parallel to the rake, or inclination of the pediment. Also, let a vertical line be drawn to each of the same points from the horizontal line rs . Make st perpendicular to the inclination of the pediment, and with a slip of paper, or by means of arcs of circles, transfer the distances on rs to the line st , and from the points thus found, draw lines parallel to st ; the intersection of these, with the inclined lines, will determine the form of the moulding, as is indicated by the letters.

When a pediment has a cornice with modillions, the caps of the modillions require to be traced by the same method.

For Skewings

23. It sometimes happens, that an inclined base-moulding has to mitre with a level one at an angle; and as the same thing occurs still more frequently with other mouldings, such as cornices under the steps of stairs, &c. we shall give another example, which will serve still farther to illustrate the method of proceeding in such cases.

In fig. 15, a raking base-moulding is shown, where the inclined moulding B is traced to mitre with the horizontal moulding C ; and the horizontal moulding A is traced to mitre with the inclined one B . The preceding examples being understood, the lines and letters in the figure will be sufficient to show how the mouldings are traced.

Remarks on Mouldings.

24. Mouldings being almost the only part of modern joiners' work, which can, in strictness, be called ornamental, and consequently that in which the taste of the workman is most apparent, we shall offer a remark or two that may have their use. The form of a moulding should be distinct and varied, forming a bold outline of a succession of curved and

flat surfaces, disposed so as to form distinct masses of light and shade. If the mouldings be of considerable length, a greater distinction of parts is necessary than in short ones.

Mouldings for the internal part of a building should not, however, have much projection; the proper degree of shade may always be given, with better effect, by deep sinkings judiciously disposed. The light in a room is not sufficiently strong, to relieve mouldings, without resorting to this method; and hence it is that quirked mouldings are so much esteemed.

SECT. II.—ON THE CONSTRUCTION OF JOINERS' WORK.

25. The goodness of joiners' work depends chiefly upon the care that has been bestowed in joining the materials. In carpentry, framing owes its strength to the form and position of its parts; but in joinery, the strength of a frame depends upon the strength of the joinings. The importance, therefore, of fitting the joints together as accurately as possible, is obvious. It is very desirable, that a joiner should be a quick workman; but it is still more so that he should be a good one; that he should join his materials with firmness and accuracy; that he should make surfaces even and smooth, mouldings true and regular, and the parts intended to move, so that they may be used with ease and freedom.

Where despatch is considered as the chief excellence of a workman, it is not probable that he will strive to improve himself in his art, further than to produce the greatest quantity of barely tolerable work with the least quantity of labour. In some articles of short duration, despatch in the manufacture may be of greater importance; but in works that ought to remain firm for years, it certainly is bad economy to spare a few shillings' worth of labour at the risk of being annoyed with a piece of bad work as long as it will hold together.

We have seen, with no small degree of pleasure, the effect of encouraging good workmanship in the construction of machinery, and would recommend that a like encouragement should be given to superior workmen in other arts.

Joining Angles.

26. When the length of a joint at an angle is not considerable, it is sufficient to cut the joint, so that when the parts are joined, the plane of the joint shall bisect the angle. This kind of joint is shown for two different angles, by fig. 16, Plate LXXXVII.

When an angle of considerable length is to be joined, and the kind of work does not require a joining should be concealed, fig. 17 is often employed: the small bead renders the appearance of the joint less objectionable, because any irregularities, from shrinkage, are not seen in the shade of the quirk of the bead.

A bead upon an angle, where the nature of the thing does not determine it to be an arris, is attended with many advantages; it is less liable to be injured, and admits of a secure joint, without the ap-

Joiner

Qualifications of a Good Joiner.

Or Joining Angles.

Joinery. appearance of one. Fig. 18 shows a joint of this description, which should always be used in passages. *

Fig. 19 represents a very good joint for an exterior angle, whether it be a long or a short one. Such a joint may be nailed both ways. But the joint represented by fig 20 is superior to it; the parts being drawn together by the form of the joint itself, they can be fitted with more accuracy, and joined with certainty. The angles of pilasters are often joined, as fig. 20.

Interior angles are commonly joined, as shown by fig. 21. If the upper or lower edge be visible, the joint is mitred, as in fig. 16, at the edge only, the other part of the joint being grooved, as in fig. 21. In this manner are put together the skirting and dado at the interior angles of rooms, the backs, and back-linings of windows, the jambs of door-ways, and various other parts of joiners' work.

Framing.

The object of Framing. 27. Frames in joinery are usually connected by mortise and tenon joints, with grooves to receive pannels. Doors, window-shutters, &c. are framed in this manner. The object in framing is, to reduce the wood into narrow pieces, so that the work may not be sensibly affected by its shrinkage; and, at the same time, it enables us to vary the surface without much labour.

From this view of the subject, the joiner will readily perceive, that neither the parts of the frame nor the pannels should be wide. And, as the frame should be composed of narrow pieces, it follows, that the pannels should not be very long, otherwise the frame will want strength. The pannels of framing should not be more than about 15 inches wide, and 4 feet long, and pannels so large as this should be avoided as much as possible.* The width of the framing is commonly about one-third of the width of the pannel.

It is of the utmost importance, in framing, that the tenons and mortises should be truly made. After a mortise has been made with the mortise chisel, it should be rendered perfectly even with a float; an instrument which differs from a single cut, or float file, only by having larger teeth. An inexperienced workman often makes his work fit too tight in one place, and too easy in another, hence the mortise is split with driving the parts together, and the work is never firm; whereas if the tenon fill the mortise equally, without using any considerable force in driving the work together, it is found to be firm and sound. The thickness of tenons should be about one-fourth of that of the framing, and the width of a tenon should never exceed about five times its thickness, otherwise, in wedging, the tenon will become bent, and bulge out of the sides of the mortise. If the rail be wide, two mortises should be made, with a space of solid wood between; fig. 22 shows the tenons for a wide rail.

In thick framing, the strength and firmness of the

Joinery. joint is much increased* by putting a cross or feather tongue in on each side of the tenon; these tongues are about an inch in length, and are easily put in with a plough proper for such purposes. The projected figure of the end of a rail, fig. 22, shows these tongues put in, in the style there are grooves ploughed to receive them.

Sometimes, in thick framing, a double tenon in the thickness is made; but we give the preference to a single one, when tongues are put in the shoulders, as we have described; because a strong tenon is better than two weak ones, and there is less difficulty in fitting one than two.

The pannels of framing should be made to fill the grooves, so as not to rattle, and yet to allow the pannels to shrink without splitting.

28. When a frame consists of curved pieces, they are often joined by means of pieces of hard wood called keys. Fig. 23 is the head of a Gothic window frame, joined with a key, with a plan of the joint below it. A cross tongue is put in on each side of the key, and the joint is tightened by means of the wedges *aa*.

It is, however, a better method to join such pieces by means of a screw bolt instead of a key, the cross tongues being used whichever method is adopted.

Joining with Glue.

29. It is seldom possible to procure boards sufficiently wide for pannels without a joint, on account of heart shakes, which open in drying. In cutting out pannels, for good work, shaken wood should be carefully avoided. That part near the pith is generally the most defective.

If the pannels be thick enough to admit of a cross or feather tongue in the joint, one should always be inserted, for then, if the joint should fail, the surfaces will be kept even, and it will prevent light passing through.

Sometimes plane surfaces of considerable width and length are introduced in joiners' work, as in dado, window backs, &c.; such surfaces are commonly formed of inch, or inch and quarter, boards joined with glue, and a cross or feather tongue ploughed into each joint. When the boards are glued together, and have become dry, tapering pieces of wood, called keys, are grooved in, across the back, with a dove-tail groove. These keys preserve the surface straight, and also allow it to shrink and expand with the changes of the weather.

30. It would be an endless task to describe all the methods that have been employed to glue up bodies of such varied forms as occur in joinery; for every joiner forms methods of his own, and merely from his being most familiar with his own process, he will perform his work, according to it, in a better manner than by another, which, to an unprejudiced mind, has manifestly the advantage over it. The end and aim of the joiner, in all these operations, is to avoid the peculiar imperfections and dis-

* Pannels of external doors and shutters may be rendered more secure by boring them, and inserting iron wires. See *Trans. Society of Arts*, Vol. XXV. p. 106.

Joinery. advantages of his materials, and to do this with the least expence of labour or material. The straightness of the fibres of wood renders it unfit for curved surfaces, at least when the curvature is considerable. Hence short pieces are glued together as nearly in the form desired as can be, and the apparent surface is covered with a thin veneer; or the work is glued up in pieces that are thin enough to bend to the required form. Sometimes a thin piece of wood is bent to the required form upon a cylinder or saddle, and blocks are jointed and glued upon the back; when the whole is completely dry it will preserve the form that had been given to it by the cylinder.

To determine the thickness of the pieces to be glued together.

The proper thickness for the pieces to be bent may be easily determined by an easy experiment on a piece of the same kind of wood. Thus, select a piece of wood, of the same kind as that to be used, and bend it as much as it will bear without injury; then ascertain the radius of curvature, and also the thickness of the piece, at the most curved part of it. From these data the proper thickness for any other curve will be determined by the following proportion:

As the radius of curvature, found by experiment, is to the thickness of the piece tried; so is the radius of any other curve to the thickness of the piece that may be bent into it.*

For example, we have found that a piece of straight grained white deal, of an inch in thickness, may be bent, without injury, into a curve of which the radius is 120 inches, therefore, 120 : 1 :: radius : thickness

radius
120 That is, a piece of deal of the same qua-

lity may be bent into any curve, of which the radius is not less than 120 times its thickness.

A piece of work glued up in thicknesses should be very well done; but it too often happens that the joints are visible, irregular, and in some places open; therefore other methods have been tried.

Bending by Steaming or Boiling.

31. If a piece of wood be boiled in water for a certain time, then taken out and immediately bent into any particular form, and it be retained in that form till it be dry, a permanent change takes place in the mechanical relations of its parts; so that, though when relieved, it will spring back a little, yet it will not return to its natural form.

The same effect may be produced by steaming wood; but though both these methods have been long practised to a considerable extent in the art of ship-building, we are not aware that any general principles have been discovered, either by experiment or otherwise, that will enable us to apply it to an art like joinery, where so much precision is required. We are aware that it has been tried; but, before it can be rendered extensively useful, the relation between the curvature to which it is bent, and that which it assumes, when relieved, should be determined, and also the degree of curvature which may be given to a piece of a given thickness.

The time that a piece of wood should be boiled,

or steamed, in order that it may be in the best state for bending, should be made the subject of experiments; and this being determined, the relation between the time and the bulk of the piece should be ascertained.

Joinery

For the joiner's purposes, we imagine, that the process might be greatly improved, by saturating the convex side of each piece with a strong solution of glue, immediately after bending it. By filling, in this manner, the extended pores, and allowing the glue to harden thoroughly before relieving the pieces, they would retain their shape better.

32. Large pieces of timber should never be used in joinery, because they cannot be procured sufficiently dry to prevent them splitting with the heat of a warm room. Therefore, the external part of columns, pilasters, and works of a like kind, should be formed of thin pieces of dry wood; and, if support be required, a post, or an iron pillar, may be placed within the exterior column. Thus, to form columns of wood, so that they shall not be liable to split, narrow pieces of wood are used, not exceeding five inches in width. These are jointed like the staves of a cask, and glued together, with short blocks glued along at each joint.

Gluing up Wooden Columns.

Fig. 24 is a plan of the lower end of a column glued up in staves; the bevel at A is used for forming the staves, that at B is used for adjusting them when they are glued together. A similar plan must be made for the upper end of the column, which will give the width of the upper end of the staves. The bevels taken from the plan, as at A and B, are not the true bevels; but they are those generally used, and are very nearly true, when the columns are not much diminished. To find the true bevels, the principle we have given in art. 19 should be applied. The same method may be adopted for forming large pillars for tables, &c.

If a column have flutes, with fillets, the joints should be in the fillets, in order to make the column as strong as possible; also, if a column be intended to have a swell in the middle, proper thickness of wood should be allowed for it.

When columns or pillars are small, they may be made of dry wood; and to secure them against splitting, a hole may be bored down the axis of each column.

Small columns, Tables, Legs, &c.

Fixing Joiners' Work.

33. We have hitherto confined our remarks to that part of joinery which is performed at the bench; but by far the most important part remains to be considered. For, however well a piece of work may have been prepared, if it be not properly fixed, it cannot fulfil its intended purpose. As in the preceding part, we shall state the general principles that ought to be made the basis of practice, and illustrate those principles by particular examples.

If the part to be fixed consist of boards jointed together, but not framed, it should be fixed so that it may shrink, or swell without splitting. The na-

* The reader will find some interesting propositions relating to flexure in the Article CARPENTRY, p. 624, Vol. II.

Joinery.

ture of the work will generally determine how this may be effected. Let us suppose that a plain back of a window is to be fixed. Fig. 25 is a section showing B the back of the window, A the window sill, D the floor, and C the skirting. The back B is supposed to be prepared, as we have stated in art. 29, and that it is kept straight by a dovetailed key *a*. Now, let the back be firmly nailed to the window sill A, and let a narrow piece *d*, with a groove, and cross tongue, in its upper edge, be fixed to bond timbers or plugs in the wall; the tongue being inserted also into a corresponding groove in the lower edge of the back B. It is obvious, that the tongue being loose, the back B may contract or expand, as a pannel in a frame. The dado of a room should be fixed in the same manner. In the principal rooms of a house, the skirting C is usually grooved into the floor D, and fixed only to the narrow piece *d*, which is called a ground. By fixing, in this manner, the skirting covers the joint, which would otherwise soon be open by the shrinking of the back; and from the skirting being grooved into the floor, but not fastened to it, there cannot be an open joint between the skirting and floor. When it is considered, that an open joint, in such a situation, must become a receptacle for dust, and a harbour for insects, the importance of adopting this method of fixing skirting will be apparent.

Fixing Skirting for Rooms.

In fixing any board above five or six inches wide, similar precautions are necessary; otherwise, it is certain to split when the house becomes inhabited. We may, in general, either fix one edge, and groove the other, so as to leave it at liberty, or fix it in the middle, and leave both edges at liberty.

Fixing Landings of Stairs, Tops of Tables, &c.

Sometimes a wide board, or a piece consisting of several boards, may be fixed by means of buttons, screwed to the back, which turn into grooves in the framing, bearers, or joists, to which it is to be fixed. If any shrinking takes place the buttons slide in the grooves. In this manner the landings of stairs are fixed, and it is much the best mode of fixing the top of a table to its frame.

Forming Architraves, &c.

34. The extension of the principle of ploughing and tonguing work together is one of the most important of the improvements that have been introduced by modern joiners. It is an easy, simple, and effectual method of combination, and one that provides against the greatest defect of timber work, its shrinkage. By means of this method, the bold mouldings of Gothic architecture can be executed with a comparatively small quantity of material; and even in the mouldings of modern architecture it saves much labour. For example, the moulded part of an architrave may be joined with the plain part, as shown by this figure.

If this method be compared with the old method of gluing one piece upon another, its advantage will be more evident.

Fixing Grounds

35. The architraves, skirtings, and surbase mouldings, are fixed to pieces of wood called grounds:

and as the straightness and accuracy of these mouldings must depend upon the care that has been taken to fix the grounds truly; it will appear, that fixing grounds, which is a part often left to inferior workmen, in reality requires much skill and attention; besides, they are almost always the guide for the plasterer. Where the plasterer's work joins the grounds, they should have a small groove ploughed in the edge to form a key for the plaster.

Joinery.

36. In our remarks on construction, we must not omit to say a few words on laying floors, because it will give us an opportunity of pointing out a defect which might be easily remedied. The advice of Evenly, to tack the boards down only the first year, and nail them down for good the next, is certainly the best, when it is convenient to adopt it; but, as this is very seldom the case, we must expect the joints to open more or less. Now these joints always admit a considerable current of cold air, and also, in an upper room, unless there be a counter floor, the ceiling below may be spoiled by spilling a little water, or even by washing the floor. To avoid this, we would recommend a tongue to be ploughed into each joint, according to the old practice. When the boards are narrow, they might be laid without any appearance of nails, in the same way as a doweled floor is laid, the tongue serving the same purpose as the dowels. In this case, we would use cross or feather tongues for the joints.

There is a method sometimes used in laying floors, which workmen call folding; according to this method, two boards are laid, and nailed at such a distance apart that the space is a little less than the aggregate width of the boards intended for it; these boards are then put to their places, and, on account of the narrowness of the space left for them, they rise like an arch between its abutments. The workmen force them down by jumping upon them. Accordingly, the boards are never soundly fixed to the joists, nor can the floor be laid with any kind of evenness or accuracy. We merely notice this method here, in order that it may be avoided.

As boards can seldom be got long enough to do without joints, it is usual, except in very inferior work, to join the ends with a tongued joint, as shown

by the figure, where B is the joist. The etched board is first laid, and nailed to the joist.

In oak floors, the ends are forked together sometimes as shown at A, in order to render the joints less conspicuous.

The joints should be kept as distant from one another as possible.

Hinging.

37. It requires a considerable degree of care to hang a door, a shutter, or any other piece of work in the best manner. In the hinge, the pin should be

Hinging Joints.

Joinery. perfectly straight, and truly cylindrical, and the parts accurately fitted together.

The hinges should be placed so that their axes may be in the same straight line, as any defect in this respect will produce a considerable strain upon the hinges every time the hanging part is moved, which prevents it from moving freely, and is injurious to the hinges.

In hanging doors, centres are often used instead of hinges; but, on account of the small quantity of friction in centres, a door moves too easily, or so that a slight draft of air accelerates it so much in falling to, that it shakes the building, and is disagreeable. We have seen this in some degree remedied by placing a small spring to receive the shock of the door.

The greatest difficulty, in hanging doors, is to make them to clear a carpet, and be close at the bottom when shut. To do this, that part of the floor which is under the door, when shut, may be made to rise above a quarter of an inch above the general level of the floor; which, with placing the hinges so as to cause the door to rise as it opens, will be sufficient, unless the carpet should be a very thick one. Several mechanical contrivances have been used for either raising the door, or adding a part to spring close to the floor as the door shuts. The latter is much the better method. The reader who may be desirous of examining this method, may consult the *Transactions of the Society of Arts*, &c. Vol. XXVI. p. 196.

38. Various kinds of hinges are in use. Sometimes they are concealed, as in the kind of joints called rule joints; others project, and are intended to let a door fold back over projecting mouldings, as in pulpit doors. When hinges project, the weight of the door acts with an increased leverage upon them, and they soon get out of order, unless they be strong and well fixed.

Room Doors. The door of a room should be hung so that, in opening the door, the interior of the room cannot be seen through the joint. This may be done by making the joint according to fig. 26. The bead should be continued round the door, and a common butt-hinge answers for it.

Fl. prop. bevel t. joints of a Door. The proper bevel for the edge of a door or sash may be found by drawing a line from the centre of motion C, fig. 27, to c, the interior angle of the rebate, draw *cd* perpendicular to *Cc*, which gives the bevel required. In practice, the bevel is usually made less, leaving an open space in the joint when the door is shut; this is done on account of the interior angle of the rebate often being filled with paint.

Stairs.

Stairs. 39. The construction of stairs is generally considered the highest department of the art of joinery, therefore we treat of it under a distinct head.

The principal object to be attended to in stairs is, that they afford a safe and easy communication between floors of different levels. The strength of a stair ought to be apparent as well as real, in order that those who ascend it may feel conscious of safety. In order to make the communication safe,

it should be guarded by a railing of proper height and strength; in order that it may be easy, the rise and width, or tread, of the steps should be regular and justly proportioned to each other, with convenient landings; there should be no winding steps, and the top of the rail should be of a convenient height for the hand.

The first person that attempted to fix the relation between the height and width of a step, upon correct principles, was, we believe, Blondel, in his *Cours d'Architecture*. If a person walking upon a level plane, move over a space, *P*, at each step, and the height which the same person could ascend vertically, with equal ease, were *H*; then, if *h* be the height of a step, and *p* its width; the relation between *p* and *h* must be such, that when *p* = *P*, *h* = 0; and when *h* = *H*, *p* = 0. These conditions are satisfied

by an equation of the form $h = H \left(1 - \frac{p}{P}\right)$. Blondel assumes 24 inches for the value of *P*, and 12 inches for that of *H*; substituting these values in

our equation, it becomes $h = \frac{1}{2} (24 - p)$, which is pre-

cisely Blondel's rule. We do not think these the true values of *P* and *H*; indeed, it would be difficult to ascertain them; but they are so near, and agree so well with our observations on stairs of easy ascent, that they may be taken for the elements of a practical rule. Hence, according as *h* or *p* is given,

we have $h = \frac{1}{2} (24 - p)$, or $p = 24 - 2h$.

Thus, if the height of a step be six inches, then $24 - 12 = 12$ the width or tread for a step that rises six inches.

40. The forms of staircases are various. In towns, where space cannot be allowed for convenient forms, they are often made triangular, circular, or elliptical, with winding steps, or of a mixed form with straight sides and circular ends. In large mansions, and in other situations, where convenience and beauty are the chief objects of attention, winding steps are never introduced when it is possible to avoid them. Good stairs, therefore, require less geometrical skill than those of an inferior character.

The best architectural effect is produced by rectangular staircases, with ornamented railing and newels. In Gothic structures scarcely any other kind can be adopted, with propriety, for a principal staircase. Modern architecture admits of greater latitude in this respect; the end of the staircase being sometimes circular, and the hand-rail continued, beginning either from a scroll or a newel.

41. When a rectangular staircase has a continued rail, it is necessary that it should be curved so as to change gradually from a level to an inclined direction. This curvature is called the *ramp* of the rail. The plan of a staircase of this kind is represented by ABCD, fig. 28, and fig. 29 shows a section of it, supposing it to be cut through at the line *ab*, on the plan.

The hand-rail is supposed to begin with a newel at the bottom, and the form of the cap of the newel ought to be determined, so that it will mitre with

the hand-rail. Let H, fig. 30, be the section of the hand-rail, and ab the radius of the cap for the newel; then the form of the cap may be traced at C by the method we have already described. (Art. 9 and 10.)

Height for
Rail, &c.

The sections of hand-rails are of various shapes; some of the most common ones are too small; a hand-rail should never be less than would require a square, of which the side is $2\frac{1}{2}$ inches, to circumscribe it.

For the level landings of a staircase the height of the top of the hand-rail should be about 40 inches, and in any part of the inclined rail the height of its upper side above the middle of the width of the step should be 40 inches less the rise of one step, when measured in a vertical direction.

To describe
the Ramps
& Rails.

To describe the ramps, let rs be a vertical line drawn through the middle of the width of the step, fig. 29; set off ru equal to rs , and draw ut at right angles with the back of the rail, cutting the horizontal line st in t . From the point t , as a centre, describe the curve of the rail. When there is a contrary flexure, as in the case before us, the method of describing the lesser curve is the same.

To draw
the Logarithmic
Spiral.

12. The hand-rail of a stair often begins from a scroll; and that kind of spiral, which is called the logarithmic spiral, has been proposed as the best for the purpose. It is shown by writers on curve lines, that any radial lines drawn from the centre will be cut by the logarithmic spiral in one and the same angle. By means of this property of the curve, it may be described as follows:

Let C be the centre, fig. 31, and draw AB perpendicular to DE, crossing it in C. Bisect the angles by the lines ab , cd . Draw eb to cut CB at the angle proposed for the curve, and to meet CB in b ; draw cb perpendicular to be , cutting Cc in c ; draw ca perpendicular to cb cutting Ca in a ; and proceed round with as many revolutions as may be required in the same manner. Then B, E, A, D, F, G, &c. are points in the curve, and the lines cb , cb , ca , ad , &c. are tangents to the curve at these points. Therefore, the curve may be either drawn by hand, or by means of circular arcs. Also, any number of interior or exterior spirals may be drawn by drawing lines parallel to the tangents, as xy , yz , &c.

If cb were to cross BC at a right-angle, the curve would be a circle.

A new Spiral
proposed
for Volutes,
Scrolls, &c.

43. The scrolls and volutes, used in architecture, are always made to terminate in a circle at the centre; consequently, none of the curves described by mathematicians are adapted for these purposes. But the construction we have employed for the logarithmic spiral readily leads to a species of spiral that appears well suited for scrolls or volutes. In the logarithmic spiral, the angle of the curve is constant; but imagine the angle to change regularly, and to become a right angle at the point, where the circle, called the eye, begins. This would afford us a regular and pleasing curve, unfolding itself from a circle in the centre. This curve might be called the Architectural Spiral.

Let C be the centre, fig. 32, and round this centre describe a circle for the eye of the scroll, or volute.

Divide this circle into eight equal parts, and draw lines from the centre through the points of division.

Joinery.

With any radius aC , and C as a centre, describe the arc ac , and upon this arc set off any number of equal divisions. The extent of a division must be regulated by the quantity the curve may unfold at each revolution, and the number depends on the number of revolutions.

Then, beginning at A, draw Ab perpendicular to Ca ; db parallel to C' ; de perpendicular to $C2$; ef parallel to $C3$; and so on for any number of revolutions. The points A, B, D, E, F, G, and H, in the curve, and the tangents to these points, are found, therefore the curve may be described by hand, or by means of circular arcs.

The tangents to any interior or exterior spiral will be parallel to the ones first found, and, therefore, any number may be drawn with the greatest facility.

Neither the logarithmic nor the architectural spiral can be drawn truly by circular arcs; but we shall here point out the principle by which such spirals may be drawn. When a spiral is drawn by means of circular arcs only, the centres of the adjoining arcs must always be upon the same straight line; and the regularity of the curve will depend on the number of arcs employed to describe one revolution. Let the proposed distance between the revolutions be divided into as many equal parts as there are to be circular arcs in one revolution; and, on the eye as a centre, construct a regular polygon of the same number of sides as the number of divisions, and each side equal to one division. Then the angles of the polygon will be the centres for describing the spiral, as shown by the figures below, where the triangle, square, and hexagon, are given as examples.

Joinery.

If a spiral be drawn to begin from a circle at the centre, let the arcs be described from the angles of a rectangular fret, as in fig. A, the sides of which may increase in any regular proportion. Or, a figure may be drawn in the same manner as the tangents of the spiral, fig. 32, and the arcs described from the angles, as in fig. B. By either of these methods a pleasing curve may be obtained.

Staircase
with Circular
land ended
Well-hole.

44. Fig. 33 represents the plan of a staircase, beginning with a scroll, and having steps winding round the circular part of the well-hole.

In the first place, let the end of the steps be developed according to the method we have given in Art. 13. Fig. 35 shows this development. Now, the hand-rail ought to follow the inclination of a line drawn to touch the nosings of the steps, except where

there is an abrupt transition from the rake of the winding to that of the other steps; at such places it must be curved; the curve may be drawn by the help of intersecting lines, as in fig. 36, if the workman cannot trust to his eye.

The part which is shaded in fig. 35 represents the development of the hand-rail and ends of the steps, when spread out, and the hand-rail is only drawn close to the steps for convenience, as it would require too much space to raise it to its proper position. This development of the rail is called the falling mould.

The wood used for hand-rails being of an expensive kind, it becomes of some importance to consider, how the plank may be cut so as to require the least quantity of material for the curved part of the rail. Now, if we were to suppose the rail executed, and a plain board laid upon the upper side of it, the board would touch the rail at three points; and a plank laid in the same position as the board would be that out of which the rail could be cut with the least waste of material.

Let it be required to find the moulds for the part *ab* of the rail, fig. 33, and to avoid confusing the lines in our small figure, the part *ab* has been drawn to a larger scale in fig. 34. The plain board, mentioned above, would touch the rail at the points marked C and B in the plan; draw the line CB, and draw a line parallel to CB, so as to touch the curve at the point E. Then E is the other point on the plan; and *a'*, *c'*, and *b'*, are the heights of these points in the development, fig. 35.

Erect perpendiculars, to CB, from the points C, E, and B, fig. 34, and set off *Ca*, on fig. 34, equal to *a'c'*, fig. 35; *Ec* equal to *de'*, and *Bb'* equal to *fb'*. Through the points C and E, draw the dotted line *Ch*; through *ae* draw a line to meet *CE* in *h*; and through the points *ab*, draw a line to meet *CB* in *g*; then join *hg*, and make *ci* perpendicular to *hg*.

Now, if *cd* be made equal to *Ca*, and perpendicular to *ci*; and *di* be joined, it will be the angle which the plank makes with the horizontal plane, or plan. Therefore, draw *FD* parallel to *ci*, and find the section by the process described in Art. 10. This section is the same thing as would be obtained by projecting vertical lines from each point in the hand-rail against the surface of a board, laid to touch it in three points. The inexperienced workman will be much assisted in applying the moulds if he acquires a clear notion of the position when executed.

To find the thickness of the plank, take the height to the under side of the rail *cr* in the development, fig. 35, and set it off from *s*, in the line *ci*, to *r*, in fig. 34; from the point *r* draw a line parallel to *di*, and the distance between those parallel lines will be the thickness of the plank.

The mould, fig. 34, which is traced from the plan, is called the *face mould*. It is applied to the upper surface of the plank, which being marked, a bevel should be set to the angle *idC*, and this bevel being applied to the edge will give the points to which the mould must be placed to mark out the under side. It is then to be sawn out, and wrought true to the mould. In applying the bevel, care should be taken to let its stock be parallel to the line *di*, if the plank should not be sufficiently wide for *di* to be its axis.

Joinery.

After the rail is truly wrought to the face mould, the falling mould, fig. 35, being applied to its convex side, will give the edge of the upper surface, and the surface itself will be formed by squaring from the convex side, holding the stock of the square always so that it would be vertical if the rail were in its proper situation. The lower surface is to be parallel to the upper one.

The sudden change of the width of the ends of the steps causes the soffit line to have a broken or irregular appearance; to avoid it the steps are made begin to wind before the curved part begins. Different methods of proportioning the ends of the steps are given by Nicholson, Ronbo, Rondelet, and Kraft. We cannot in this place enter into a detail of these methods, but for the reader's information a list of the principal writers on staircases is subjoined.

Price, in his *British Carpenter*, 4to, 1735; Langley, *Builders' Complete Assistant*, 8vo, 1738; Frezier, *Coupe des Pierres et des Bois*, 4to, 1739; Ronbo, *L'Art du Menuisier*, folio, 1771; Skaife, *Key to Civil Architecture*, 8vo, 1774; Nicholson, *Carpenters' New Guide*, 4to, 1792; *Carpenters' and Joiners' Assistant*, 4to, 1792; *Architectural Dictionary*, 4to; *Transactions Society of Arts, &c.* for 1814; *Treatise on the Construction of Staircases and Hand-rails*, 4to, 1820; Rondelet, *Traité de l'Art de Bâtir*, Tome IV. 4to, 1814; and Kraft, *Traité sur l'Art de la Charpenter*, Part II. folio, 1820.

SECT. III.—ON MATERIALS.

Importance of the subject.

15. There is no art in which it is required, that the structure and properties of wood should be so thoroughly understood as in joinery. The practical joiner, who has made the nature of timber his study, has always a most decided advantage over those who have neglected this most important part of the art.

In the article ANATOMY, VEGETABLE (*Supplement*), Vol. I. p. 306 and 332, the structure of wood is described; in this place, therefore, we shall only show how the joiner may, in a great measure, avoid the warping caused by its irregular texture.

Boards cut in a particular direction will not retain their form.

46. It is well known that wood contracts less in proportion, in diameter, than it does in circumference; hence a whole tree always splits in drying. Mr Knight has shown that, in consequence of this irregular contraction, a board may be cut from a tree, that can scarcely be made, by any means, to retain the same form and position when subjected to various degrees of heat and moisture. From the ash and the beech he cut some thin boards, in different directions relatively to their transverse septa, so that the septa crossed the middle of some of the boards at right angles, and lay nearly parallel with the surfaces of others. Both kinds were placed in a warm room, under perfectly similar circumstances. Those which had been formed by cutting across the transverse septa, as at A in the figure, soon changed their

form very considerably, the one side becoming hollow, and the other round; and in drying, they contracted nearly 14 per cent. in width.

Joinery.

The other kind in which the septa were nearly parallel to the surfaces of the boards, as at B in the marginal figure, retained, with very little variation, their primary form, and did not contract in drying more than three and a half per cent. in width.*

As Mr Knight had not tried resinous woods, two specimens were cut from a piece of Memel timber; and, to render the result of our observation more clear, conceive the figure to represent the section of a tree, the annual rings being shown by circles. BD represents the manner in which one of our pieces was cut, and AC the other. The board AC contracted 3.75 per cent. in width, and became hollow on the side marked b. The board BD retained its original straightness, and contracted only 0.7 per cent. The difference in the quantity of contraction is still greater than in hard woods.

From these experiments the advantages to be obtained, merely by a proper attention in cutting out boards for pannels, &c. will be obvious; and it will also be found, that pannels cut so that the septa are nearly parallel to their faces, will appear of a finer and more even grain, and require less labour to make their surfaces even and smooth.

The results of these experiments are not less interesting to cabinet-makers, particularly in the construction of billiard-tables, card-tables, and indeed every kind of table in use. For such purposes the planks should be cut so as to cross the rings as nearly in the direction BD as possible. We have no doubt that it is the knowledge of this property of wood, that renders the billiard-tables of some makers so far superior to those of others.

In wood that has the larger transverse septa, as the oak, for example, boards cut as BD will be figured, while those cut as AC will be plain.

47. There is another kind of contraction in wood whilst drying, which causes it to become curved in the direction of its length. In the long styles of framing we have often observed it; indeed, on this account, it is difficult to prevent the style of a door, hung with centres, from curving, so as to rub against the jamb. A very satisfactory reason for this kind of curving has been given by Mr Knight,† which also points out the manner of cutting out wood, so as to be less subject to this defect, which it is most desirable to avoid. The interior layers of wood, being older, are more compact and solid than the exterior layers of the same tree; consequently, in drying, the

* *Philosophical Transactions*, Part II. for 1817, or *Philosophical Magazine*, Vol. L. p. 437.

† *Ibid*.

JOINERY.

Joinery. **latter contract more in length than the former. This irregularity of contraction causes the wood to curve, in direction of its length, and it may be avoided by cutting the wood so that the parts of each piece shall be as nearly of the same age as possible.**

Changes
produced by
the Wea-
ther.

48. Besides the contraction which takes place in drying, wood undergoes a considerable change in bulk with the variations of the atmosphere. In straight grained woods the change in length is nearly insensible,* hence they are sometimes employed for pendulum rods; but the lateral dimensions vary so much, that a wide piece of wood will serve as a rude hygrometer.† The extent of variation decreases in a few seasons, but it is of some importance to the joiner to be aware, that, even in very old wood, when the surface is removed, the extent of variation is nearly the same as in new wood.

It appears, from Rondelet's experiments,‡ that in wood of a mean degree of dryness, the extent of contraction and expansion produced by the usual changes in the state of the atmosphere, was,

in fir wood, from $\frac{1}{360}$ to $\frac{1}{75}$ part of its width;

and, in oak, from $\frac{1}{412}$ to $\frac{1}{84}$ part of its width.

Consequently, the mean extent of variation in fir is $\frac{1}{124}$, and, in oak, $\frac{1}{140}$; and, at this mean rate, in a

fir board about 12½ inches wide, the difference in width would be $\frac{1}{10}$ th of an inch. This will show the importance of attending to the maxims of construction we have already laid before the reader; for, if a board of that width should be fixed at both edges, it must unavoidably split from one end to the other.

Kinds of
Wood.

49. The kinds of wood commonly employed in joinery are, the oak, the different species of pine, mahogany, lime-tree, and poplar.

Of the oak, there are two species common in this island; that which Linnaeus has named *Quercus robur* is the most valuable for joiners' work; it is of a finer grain, less tough, and not so subject to twist as the other kind. Oak is also imported from the Baltic ports, from Germany, and from America. These foreign kinds being more free from knots, of a

straighter grain, and less difficult to work, they are used in preference to our home species. Foreign oak is also much used for cabinet-work, and lately, the fine curled oak, that is got from excrescences produced by pollard, and other old trees, has been used with success in furniture. When well managed it is very beautiful, and makes a pleasing variety. It is relieved by inlaid borders of black or white wood, but these should be sparingly used. Borders of inlaid brass, with small black lines, give a rich effect to the darker coloured kinds.

The greater part of joiners' work is executed in Fir, yellow fir, imported from the north of Europe; white fir is often used for internal work, and American pine is much used for mouldings.

The forest of Braemar, in Aberdeenshire, furnishes yellow fir of an excellent quality, little inferior to the best foreign kinds.

For the general purpose of joinery, the wood of Larch the larch tree seems to be the best; this useful tree thrives well on our native hills. We have seen some fine specimens of this wood from Blair Athol. It makes excellent steps for stairs, floors, framing, and most other articles.

Mahogany, in joinery, is used only where painted Mahogany work is improper, as for the hand-rails of stairs, or for the doors and windows of principal rooms. For doors, it is not now so often used as it was formerly; its colour is found to be too gloomy to be employed in large masses. In cabinet-work it is almost the only kind employed for ornamental work.

Lime-tree, and the different species of poplar, Lime-tree, make very good floors for inferior rooms, and may often be used for other purposes in places where the carriage of foreign timber would render it very expensive. Lime-tree is valuable for carved work, and does not worm eat; but carving is, at present, seldom used in joinery.

For farther information on wood, in addition to the works referred to, the reader may consult Evelyn's *Silva*, Dr Hunter's edition; Duhamel, *Du Transport, de la Conservation, et de la Force des Bois*, Paris, 1767; Barlow's *Essay on the Strength and Stress of Timber*, 1817; Tredgold's *Elementary Principles of Carpentry*, Sect. X. 1820; and the article Dry-Rot in this Supplement.|| (H. H. H.)

* Mr Ransden and General Roy made some experiments on the expansion in length. See *Account of the Trig. Survey*, Vol. I. p. 46 and 49.

† See *Phil. Trans.* Lowthorpe's Abridg. Vol. II. p. 27.

‡ *Traité Théorique et Pratique de l'Art de Bâtir*, article MENUISERIE, Tome IV. p. 425, 1814.

|| The roof of Westminster Hall being now under repair, the opportunity has been taken to examine the wood of which it is constructed; and it is found to be of oak, and not of chesnut, as stated in the Article Dry-Rot, Vol. III. p. 684. The oak has been of an excellent kind, but is now much worm-eaten.

IONIAN ISLANDS.

Ionian
Islands.

THE Ionian Islands formed, lately, a small part of the Venetian dominions; and, by a fate somewhat singular, they have been raised to the rank of an independent power without any efforts of their own, at the very period which witnessed the extinction of Venice itself, with Genoa, Ragusa, and many other small states that had existed for ages. These islands, which are seven in number, exclusive of some small dependent islets, are situated on the western and southern shores of Greece, between 36° and 40° of north latitude; and between $19^{\circ} 40'$ and $23^{\circ} 10'$ of

east longitude. Four of them lie in a group opposite the entrance of the gulf of Corinth; other two, Corfu and Paxo, are situated about eighty miles north-west of this central group; from which Cerigo, the remaining island, lies about 150 miles south-east. The subjoined table gives a view of their extent and population; but the measurement can only be considered as approximations, as, we believe, no accurate map of all the islands has ever been published.

Ionian
Islands.

Modern Names.	Ancients' Names.	English Square Miles.	Population.	Authorities.
* Cephalonia,	Cephalenia,	500	60,000	Holland, 1812.
Corfu,	Corcyra. Phæacia,	270	60,000	Vaudoncourt, 1807.
Zante,	Zacynthus,	180	33,352	Williams, 1815.
Santa Maura,	Leucadia,	150	18,000	Holland, 1812.
Cerigo,	Cythera,	130	9,000	Do. 1811.
Theaki,	Ithaca,	60	9,400	Williams, 1815.
Paxo,	Paxus,	20	3,968	Do.
		1310	193,720	

According to this table, these islands contain about 150 persons to each square mile, a density of population nearly equal to that of the most populous countries of Europe, and very remarkable, considering how a great a proportion of their surface is too rugged to admit of any species of cultivation.

Climate and
Diseases.

The climate of the Ionian Islands resembles that of the continent of Greece, except that the surrounding seas temper in a greater degree the extremes of heat and cold, and render the atmosphere more humid. Snow often falls during the winter, and lies on the high grounds, but very rarely in the plains. The winter rains sometimes bring with them great quantities of a reddish sand, which the people think has been transported from Africa by the south wind. Sudden and furious squalls are frequent, and the Sirocco, or hot wind, which occurs at certain periods, produces the usual effects, a dull headach, lassitude, and a sense of oppression. The harvest, which is generally in May on the continent, is here in June. Earthquakes are very frequent, though not often very destructive. In Zante, two or three sometimes occur in a month; it is observed that

they are preceded by a peculiar state of the atmosphere, producing a feeling of heaviness, or a sulphurous smell, and that they are generally followed by rain. Malaria prevails in low situations in the autumnal months; and the itch, which is common in some parts, instead of being eradicated by medical means, is rather cherished by the people, from a strange notion that it is a preservative against malaria. In other respects, the climate is agreeable and healthy, and instances of remarkable longevity are known.†

The rocks of all these islands belong to the same Geological great calcareous formation which occupies the continent of Greece. They contain some, though very few, organic remains, and are disposed in highly inclined strata. The limestone, which is accompanied occasionally with beds of grey foliated gypsum, and with beds or masses of sandstone, is conjectured by Dr Holland to belong to the first flætz limestone of Werner. At one spot, ten miles south of the town of Zante, are found a number of pitch wells, agreeing in their situation and appearance with the description given by Herodotus, two thousand four hundred years ago. They consist of small pools of

* The ancient geographers had a very imperfect idea of the extent of these islands. Strabo (Lib. x.) estimates the circumference of Cephalo. at 30 miles (300 stadia), instead of 100; that of Zante at 16 miles, instead of 60, and that of Ithaca at 8 miles, instead of 40. Pliny (Lib. iv.) gives 44 Roman miles as the circumference of Cephalonia, and 36 as that of Zante.

Ionian
Islands.

water, fed by springs, in a marshy tract near the shore, having their sides and bottoms lined with petroleum in a viscid state, which, by agitation, is raised to the surface in flakes. It is collected once a year, and the produce is about a hundred barrels. (Holland, Chap. i. and ii.)

Topogra-
phy.

The surface of all these islands is so remarkably mountainous, that they do not contain a quantity of arable land nearly sufficient to afford corn to the population; and were it not that the vine, the olive, and the currant, enable them to extract a valuable produce from their rocks and declivities, they could support but a very small number of inhabitants. There is a considerable diversity, however, in the aspect and qualities of the surface of the different islands, which renders it necessary to speak of their topography separately. To begin with Corfu, the most northern, and the seat of the general government. This island, which is about 40 English miles long, and 15 in extreme breadth, lies opposite the coast of Albania, from which it is separated at one point by a strait two miles broad. A range of mountains occupies the centre of this island, the highest summits of which, Mount Kassopo, must be nearly 4000 feet high, since the coast of Italy, at 80 miles distance, is visible from it. The island is rather bare of wood, and not abundant in good pasture. Wheat is raised in some low situations near the coast; but though called *fruitful Corcyra* by Dionysius, and celebrated for its riches by other ancient authors, its inhabitants depend chiefly on importation for corn, which they procure in exchange for their wine, oil, and salt. The capital, also named Corfu, which lies on the east side of the island, contains about 15,000 inhabitants, and is a pretty strong place. This island is the Phæacia of Homer. A small bay, five or six miles south of the capital, is conceived to be the Alcineus Portus, where Ulysses, after his shipwreck, met with the daughter of Alcineus; and Fano, a small rocky inlet seven or eight miles in circumference, lying twelve miles off the north-west coast of Corfu, is the island of Calypso.*

Paxo, the next in order, which is about seven miles long, and three broad, lies eight miles south-east of Corfu, and twelve miles west of the coast of Albania. Its surface is highly beautiful, much inclosed, and nearly covered with olive trees. Its capital, St Gago, contains a great proportion of the population, amounting to 3948 persons, who depend very much on trade for their subsistence. Antipaxo, an inlet five or six miles in circumference, and inhabited by a few fishermen, lies near it. (Vaudoncourt, Chap. xi.; Williams, Ict. xlviii.)

Leucadia.

Santa Maura, about twenty miles long, and eight or nine broad, lies so close to the coast of Greece, that it was formerly joined to it by an isthmus. It is sixty miles south-east from Corfu, three miles from Ithaca, and five from the nearest point of Cephalonia. The surface consists of a range of limestone mountains, which rise to the height of nearly 2000 feet, and terminate on the south-west, in the cele-

Ionian
Islands

brated Leucadian promontory, where unhappy lovers, following the example of Sappho, came to cure themselves of an unrequited passion. The cliff is not very lofty, though sufficiently so for the purpose to which it was applied. It is still the custom of the neighbouring mariners, when passing, to throw in a small piece of money, as an expiatory offering. The island contains very little level surface. Its principal products are olives and vines; and salt is made on the coast. The capital, also named Santa Maura, containing 5000 inhabitants, is situated at the northern point of the island, where it is separated by a narrow channel from the continent. The ancient name Leucadia, or, as it is now pronounced, Lefcadia, is still known among the inhabitants, and ought to be used to distinguish the island from its capital. (Holland, Chap. iii.; Vaudoncourt, Chap. xi.)

Theaki, the ancient Ithaca, the regal seat of Ulysses, consists merely of a narrow ridge of limestone, seventeen miles long, and four in extreme breadth, rising into rugged eminences, with scarcely a hundred yards of continuous level surface in its whole extent. Near the middle, it is intersected by a deep bay, which penetrates four miles inwards. Upon this bay the town of Vathi, the capital, is situated, containing 2000 inhabitants. The chief produce of the island is currants; but it yields, also, a small quantity of oil and wine, the latter much esteemed. The grain raised suffices only for three months' consumption. On a hill near Vathi are some massive ruins of ancient walls, with a number of sepulchres, which are supposed to mark the site of the capital of Ulysses. Near the south-east end of the island is a cliff called Koraka at present, and supposed to be the rock Korax, mentioned in the Odyssey, and under it, in a secluded and picturesque spot, is a fountain, conceived to be that of Arethusa, where Ulysses met the faithful Eumæus. The island is still named Ithaca by the more intelligent natives, which is corrupted into Theaki by some of the lower classes. Between Ithaca, Santa Maura, and the continent, are situated four small rocky isles, named Meganisi, Calamo, Atako, and Carto, besides several minute islets, of little or no importance. (Holland, Chap. iii.)

Cephalonia, three miles from the nearest point of Ithaca, is the largest of all the Ionian Islands. Its greatest length is forty English miles, and greatest breadth twenty-four. A lofty chain of mountains, the Mount Ænos of antiquity, nearly 4000 feet high, occupies the centre of the island, and sends off branches to all the principal promontories. The wood which covered a part of these hills was wantonly burnt, about twenty years ago, during some internal disturbances. A deep gulf penetrates far inland from the south side of the island: and, upon the east side of this gulf stands Argostoli, the capital, containing 4000 inhabitants. Lixuri, the only other town, contains 5000 inhabitants; and there are, in the island, 175 villages. (Turner, 192.) The surface of Cephalonia is generally rocky; the soil thin, and less fertile than that of Zante. Its chief productions

* *Memoirs of the Ionian Islands*, by General Guillaume De Vaudoncourt, translated by Mr Walton. Chap. xi.

Ionian
Islands.

are currants, oil, and wine. Some ruins of Cyclopi-
an walls mark the site of the city of Samus, mentioned
by Homer; and there are some remains of Krani,
Pronos, and other ancient cities. Vestiges of the al-
tar of Jupiter Ænesius are said still to exist on the
top of Mount Ænos. (Holland, Chap. ii.)

Zante.

Zante, which lies ten miles south from the nearest
point of Cephalonia, is about sixty miles in circum-
ference. Unlike the neighbouring islands, its sur-
face consists chiefly of a large plain, reaching from
the southern to the northern coast, but bounded on
the east and west sides by calcareous ridges, about
1200 or 1300 feet high. This plain, covered with
vineyards and olive groves, with only a few spots in
tillage, presents the appearance of luxuriant fertility,
and has procured for the island the title of the "Gar-
den of the Levant." The capital, Zante, situated
on the east side of the island, contains 18,000 in-
habitants. Zante contains very few antiquities; and
though smaller, and inferior in population to some of
the other islands, is the richest of them all. (Hol-
land, Chap. i.)

Cerigo, the ancient Cythera, the last of the seven
islands, is about 50 miles in circumference, and is si-
tuated near the south coast of the ancient Laconia,
150 miles from the nearest of its Ionian confederates.
The face of the island is mountainous, and though
reported to be the birth place of Venus, it is rug-
ged, barren, and destitute of beauty. Its produc-
tions are similar to those of the other islands, but it
is less commercial, and abounding more in pasturage,
it raises a considerable number of sheep and cattle.*

Agricul-
ture.

Landed property, in all the islands, is in the
hands of a comparatively small number of persons,
who form a proud, oppressive, and rapacious aristo-
cracy. The Venetian senate, while it possessed
these islands, kept all the more solid advantages to
its own citizens, but bestowed titles, which cost
nothing, profusely upon the petty insular chief-
tains; and nobles, destitute of education, honour,
or property, are as common here as in Italy. The
lands are generally let by the year, the tenant pay-
ing half the produce to the landlord,—a species of
tenure almost universal in rude countries. In Ce-
phalonia, where property is pretty much divided,
the largest proprietor has not above L.800 or L.900
a-year; but in Zante there are estates of more than
double this value. (Holland, 36.) In the rural eco-
nomy of the Ionian Islands, corn is an object of se-
condary importance, and farming is conducted on
the rudest principles. Barley, wheat, maize, and
oats, are cultivated, but the quantity of grain of all
kinds raised does not exceed one-half, and in some
of the islands is not one-third, of the annual amount
of consumption. Of the corn raised in Ithaca,
one-tenth is wheat, and nine-tenths barley. The re-
turns of the former are estimated at 6 or 7, and of

the latter at 8 or 9 for 1. (Williams, *Appendix*,
No. iii.) Flax and cotton are cultivated to a small
extent in several of the islands. Cephalonia is com-
puted to yield of the latter 100,000 pounds annual-
ly, of an excellent quality. (Vaudoncourt, 438.)
The number of oxen, sheep, and goats, is consid-
erable in the islands less adapted to the cultivation of
the currant, vine, or corn: but others, such as Zante,
have very few, and all are partly supplied with cattle
and poultry from the Morea. Milk cows are rare,
the milk of goats being preferred for ordinary use,
as well as for the manufacture of cheese. The pro-
duce of wax and honey in some of the islands is very
great. Cerigo is stated to have had 1280 hives in
1811, and 60,000 or 80,000 pounds of honey of an
excellent quality are collected annually in Cephalo-
nia. (Vaudoncourt, 437. Holland, 43.)

Ionian
Islands.

The cultivation of vines and olives is an object of
greater attention to the inhabitants than that of
corn, and is more skillfully conducted. Nine sorts
of olives grow in Zante, differing considerably in
their qualities. The fruit begins to ripen in Novem-
ber, but does not fall off till towards the end of De-
cember, or the beginning of January. This is the
time when they are gathered, but in some places
they are plucked with the hand, and not allowed to
fall. They are carried to the mill in April, but the
harvest is not entirely at an end till the month of
May. The oil is carried to the sea ports in sheep
skins. Olives are cultivated to the greatest extent
in Corfu, where the produce collected every two
years amounts, in middling seasons, to 700,000 jars,
or 90,000 barrels,† annually. Zante produces about
30,000 barrels; Cephalonia, 30,000; Leucadia, 3000;
Paxa, 8500; and Ithaca, 1500. Including Cerigo,
the annual produce of olive oil will not be much less
than 200,000 barrels. While the Venetians were
masters of the island, and retained a monopoly of the
oil trade, the price averaged from 40 to 43 livres of
Corfu (6s. 8d. to 7s. 2d.) per jar; but in 1802 it rose
to 60 livres (10s.); and in 1807 (a dear year) was
17½ dollars per barrel, or about 19s. per jar. The oil
is of four different qualities, the finest of which is fit
for the table, and the other three species are used in
various manufactures.‡

Wine is made in all the islands to a small extent. Grape
In Zante, forty species of grape are distinguished,
but the small black species, known under the name
of currants, is the only kind extensively cultivated.
Ithaca produces about 12,000 barrels of wine annu-
ally, of a quality superior to that of the other islands,
and which sells about 20 dollars per barrel. Cepha-
lonia produces from 30,000 to 35,000 barrels of
good wine. Zante yields only about 4000 barrels;
Leucadia 1000. The produce of the other islands
is not known.§ Oranges, lemons, and citrons, are
raised in several of the islands, both for domestic use

* Galt's *Voyages and Travels*, 1812, p. 137. Holland, Chap. iii.

† The barrel rather exceeds the millerole of Marseilles, or 59.7 litres (Vaudoncourt); and, according to Williams, is equal to 128 English pints. These accounts agree, and the barrel may therefore be considered as one-fourth of a hogshead.

‡ Vaudoncourt, Chap. xii. Holland, Chap. ii. and iii. Williams, p. 173, and *Appendix*, No. iii. Walpole's *Memoirs relating to Turkey*, p. 288.

§ Holland, p. 22. Vaudoncourt, Chap. xii. Williams, *Appendix*, No. iii.

Ionian
Islands.
Currants.

and exportation; and salt is supplied for exportation in large quantities from Corfu and Leucadia.

The currant is the staple produce of Zante, where it occupies nearly two-thirds of the cultivated land. It is raised also in Cephalonia and Ithaca, but does not succeed in Corfu or Leucadia. Its culture is conducted with great neatness, and when the flower is out, the aspect of the great vineyards is singularly rich and beautiful. It thrives best in a deep soil, at the foot of mountains. The currants are gathered about the beginning of September, somewhat sooner than other grapes; are spread abroad for eight or ten days, and are usually ready for packing by the end of September. The annual produce of Zante is from 7,000,000 to 8,000,000 pounds, the price of which in the island varies from 14s. to 18s. per hundred weight. Cephalonia yields from 5,000,000 to 6,000,000 pounds, and Ithaca 500,000. The whole produce of the Ionian Islands in this article may therefore be estimated at 13,000,000 or 14,000,000 pounds. (Holland, Chap. ii. and iii. Vaudoucourt, chap. xii.)

Annual
Produce.

Mr Williams gives the estimated value of the annual produce of the three islands Zante, Paxo, and Ithaca, in corn, wine, oil, currants, honey, and flax, the chief productions, but excluding minor articles, such as cheese, fruit, &c. The estimates appear to be official, and as they are probably deduced from surveys made for the purpose of taxation, they are entitled to some degree of confidence; but it would have been more satisfactory had he stated upon what basis they were formed. The annual produce of Zante, in 1815, is stated at 1,066,745 dollars, or L.234,000; that of Ithaca, 98,896 dollars, or L.22,000; that of Paxo, 104,018 dollars, or L.23,000. These three statements give, on an average, L.6 Sterling of produce for each inhabitant, but, as some of the other islands are less favourably situated, L.5 is probably high enough, as a mean, and if we compute the annual value of the produce of the whole on this principle, it will be L.970,000 (Williams, 72-183, and Appendix, No. iii.), or, in round numbers, L.1,000,000 Sterling, and this is exclusive of what is derived from commerce and the mechanic arts.

Commerce.

The situation of the Ionian Islands gives them naturally, and in some measure necessarily, a commercial character. Their position, near the coast of Greece, where the tyranny of the Turks renders property so insecure, tends to make them a medium of communication with that country, and an entrepot for its commodities. The narrowness of their territories, which obliges them to import provisions, and the peculiar nature of the soil and climate, which are better adapted to raise other productions than corn; their insular situation, and long connection with the Venetians,—all dispose them to engage largely in commercial transactions. The trade of the islands, considering their extent and circumstances, is, in truth, considerable, and has increased greatly since it was freed from the shackles imposed upon it by the monopolising spirit of the Venetians. The exports consist of olive oil, currants, wine, honey, wax, salt, soap, oranges, lemons, tobacco, cheese, &c. The

imports are corn, woollen, cotton, and linen goods, velvets, cured fish of various kinds, sugar, coffee, iron, lead, dye-stuffs, paper, drugs, spices, &c. Zante, in 1815, exported goods to the value of 591,000 dollars. Cephalonia has 250 vessels of various sizes. The little island of Paxo has 56 vessels, and exported goods to the value of 96,000 dollars in 1815. Ithaca, in 1815 or 1816, had 2598 tons of shipping, which, with boats belonging to the island, employed 828 men, and 74,360 dollars of capital. The little island of Cerigo, the least commercial of the whole, had, in 1809, only about 25 vessels, nearly all boats, employing 230 men. The number of Ionian vessels that trade with Turkey was estimated, in 1816, at 250, of which 200 were under their own flag, and 50 under the Russians. We should probably not err much if we estimated the exports of the whole islands at something more than double those of Zante, or about one-third of the computed gross produce of the land, namely, L.300,000 Sterling. A great number of their vessels trade with the Russian ports in the Black Sea for corn, others with Malta, Greece, Italy, France, and Spain. In the intercourse between the islands which lie near one another, a species of long slender boat is used, named *Monoxylon*, made of a single piece of wood, preserving both the form and the name of the vessels used in earliest and rudest stage of Greek navigation. (Potter's *Antiquities*, Book iii. Chap. xiv.) The interest of money, in common cases, is 10 per cent. The merchants are generally poor and unenterprising, but a few individuals have accumulated considerable fortunes. (Williams, Vol. II. 183.) One individual, a nobleman is mentioned, who is said to possess a million of dollars. If these islands continue to enjoy tranquillity, and if their internal economy is improved, it is probable they will attract a considerable part of the trade which now centres in Salonica, Hydra, Spechia, and other Turkish ports, where the merchants are exposed to loss and vexation from the rapacity and violence of the Turkish government.*

The public revenue arises from a tithe or impost on the various species of produce raised within the country, grain, wine, oil, flax, and cattle; from a tax on hearths or inhabited houses, a tax on oil presses, and from duties of customs on articles exported and imported. The produce of these various duties, in 1815, was as follows:

REVENUE.

	Eventual Revenues.	Fixed Revenues.	Totals.
	Dollars.	Dollars.	Dollars.
Zante, . . .	71,779	83,015	154,795

(Williams's *Travels*, Appendix, Nos. ii. and iii.)

This small expenditure appears to include only the charges of the civil government, and perhaps not the whole of these. The body of 3000 troops, chiefly British, kept in the islands, would alone evidently absorb a larger revenue. And although it was fixed by the constitution, that the islands should defray the expence of their own military establishment, it appears in point of fact, from a Parliamentary paper (dated 25th February 1820, No. 87), that the British Government incurred an expence of L.145,203 in the Ionian Islands in 1817, and L.120,045 in 1818, for purposes chiefly military, but partly civil. It is difficult to conceive, that there can be any British objects in that quarter requiring such an expenditure, or that the money has been advanced provisionally, to be afterwards repaid, since the revenues of the islands must now be on a permanent footing. There remains but one admissible supposition, that these islands are to form a permanent burden on the people of Britain; and yet, at a period when our own expenditure presses so heavily, it seems little less than infatuation, to increase our difficulties gratuitously, by relieving a distant country less heavily taxed of the expence of defending itself.

Constitu-
tion.

The existing constitution of the Ionian Islands, which was sanctioned by its own Legislative Assembly in May 1817, vests the supreme power in the High Commissioner, the Senate, and the Legislative Assembly, which have jointly the title of the Parliament of the Ionian Islands. The Legislative Assembly consists of 40 members, of whom 29 are elective, and 11 *integral*, and all must belong to the class of *Synchtae*, or nobles, the common people having nothing to do with the laws, but to obey them. The 11 *integral* members consist of the president and members of the old Senate, with the regents or governors of the five largest islands—all of whom are substantially, though not directly, nominated by the High Commissioner. The 29 elective members are chosen by the nobles of the different islands, from prepared lists sent down by the Primary Council, in the following proportions:

Corfu, . . .	7
Cephalonia, . .	7
Zante, . . .	7
Leucadia, . . .	4
Ithaca, . . .	1
Cerigo, . . .	1
Paxo, . . .	1
	<hr/> 28

Ionian
Islands.

And each of the three last in rotation elects a second member, which makes 29. The Legislative Assembly elects its own officers; fixes the amount of the supplies; and all its members have the power of proposing new laws or regulations.

The Primary Council, mentioned above, which acts only during a dissolution of Parliament, consists of the president and members of the last Senate, with five members of the last Legislative Assembly, nominated by the High Commissioner.

The Senate consists of five members and a president, the latter appointed directly by the High Commissioner. The five members are elected by the Legislative Body out of its own number, and confirmed by the High Commissioner. If he negative the election of an individual, another is elected; and if he negative the second also, the vacancy is filled up by his nominating two individuals, of whom it then falls to the Legislative Body to choose one. This Senate is an executive council, as well as a deliberative body. It nominates most of the officers under the general government, such as judges, regents, archivists, &c. but its nominations must be confirmed by the High Commissioner. It makes regulations during the recess of the Legislative Assembly, which have, *pro tempore*, the force of laws; and it deliberates and decides upon all propositions submitted to it by the High Commissioner, or sent up from the Lower House, but its members have not a power to initiate legislative proceedings.

The Legislative Assembly and the Senate are elected for five years, but may be dissolved at the lapse of a shorter period by the High Commissioner. The appointments of judges, regents, and other officers, are also for five years.

The High Commissioner is nominated by the protecting sovereign. He appoints the president of the Senate, who has the initiative of all proceedings in that body. He appoints a resident for each of the islands, who has the power of suspending any proceeding of the local government. He nominates a number of officers, and has a negative (direct or indirect) upon the appointment of most of those whom he does not nominate. He has a *veto* on all propositions which have passed the two houses; but though he give his sanction to any specific measure, there is still another *veto* behind, lodged in the King of Britain, who may annul the proceeding at any period within one year of its enactment.

Each island has a local government, consisting of a municipal council of five members, selected by the regent (with the approbation of the High Commissioner), out of a list of ten, chosen by the *synchtae*. Besides these, there are five active functionaries, —a regent, secretary, fiscal, archivist, and treasurer, —all, except the last, nominated by the Senate, and confirmed by the High Commissioner.

The judicial power is lodged in a supreme court at the seat of government, consisting of four ordinary, and two extraordinary members. Of the former, two are native Ionians, named by the Senate, and approved of by the Commissioner; and two directly named by the Commissioner, may either be British subjects or Ionians. When these four are equally divided on any question, reference is made to the two extraordinary members, who are the High

Ionian
Islands.

Commissioner and President of the Senate. Subordinate to this supreme court are twenty-one inferior tribunals, that is, a civil, a criminal, and a commercial tribunal in each island. And under these, again, are justice of peace courts, for minor offences, and small civil suits. Besides the general appellant jurisdiction, which the supreme court has over the local tribunals, it is empowered to send a delegation of its members on circuit on special occasions, when thought necessary by the Senate and High Commissioner. The number of judges in the local courts is not fixed by the constitution.

The *Saṇita*, or Health Establishment, is under the sole direction of the High Commissioner. The army, consisting entirely of the troops of the protecting sovereign, is also under the orders of his representative. The expense of the army is to be defrayed by the islands, if the number does not exceed 3000 men. There is, besides, a national militia, commanded by native officers.

Individuals, or bodies of men, have the right of representation or petition to the protecting sovereign or his ministers.

A printing press is to be established at the seat of government, under the "immediate control of the Senate and High Commissioner," and "no other printing press shall be set up and employed, without the previous licence of the Senate, and the sanction of his Excellency."*

We have described this constitution more in detail than its importance merits, for, without exaggeration, it may certainly be pronounced to be the very worst among the numerous plans of representative government framed within the last thirty years. It is, in fact, little else than a compact between the British government and the petty despots of the islands, settling in what proportions the power, patronage, and taxes of the country are to be shared between them. The rights and interests of the mass of the people, for which even the German princes in their new constitutions profess a decent respect, are not the object of one single stipulation in this long and detailed instrument.

The style of building in the Ionian Islands is chiefly Italian, and the interior of some of the cities shows great neatness. The streets are generally narrow; the houses, some of wood, some of stone, are three, four, or even five stories high, with open latticed windows. The shops are tolerably well supplied with manufactured and colonial articles, and the persons employed in them display more alertness and civility than the indolent shop-keepers of Spain, Portugal, and Sicily. The churches, as in Greece, are disproportionately numerous. Some of them have steeples, others have merely an elevated facade. The population, in consequence of the long dominion of the Venetians, is, in manners and habits, as well as in costume and language, intermediate between the Greek and Italian character. Though enjoying more liberty, they are, in some respects, inferior to the continental Greeks. Their exterior is less dignified, their manners more corrupt, and

Ionian
Islands.

they show less capability of again becoming a people. This degradation of character may be attributed chiefly to the vicious nature of the Venetian government. The governors and judges whom it sent out to the islands were very often nobles of decayed fortune, who undertook the duties as a speculation to retrieve their affairs. Bribery was practised openly; toleration for a crime might easily be purchased; and the laws, imperfect in themselves, were rendered wholly null by the corruption of the judges. The petty insular aristocracy separated into factions, which trampled on the laws and oppressed the people. The Venetian government, by a detestable policy, encouraged their feuds, to prevent their combination, and exposed the country to all the evils of a continued civil war. As happens in all countries where justice is denied by the laws, private revenge and assassination prevailed to a frightful extent. In the island of Zante alone, with 33,000 inhabitants, the number of assassinations sometimes exceeded one for each day of the year. Many of the nobles, indeed, kept assassins in their pay, and others of them fitted out privateers for the trade of general piracy, in which the vessels of their own countrymen were not spared. These nobles are generally educated in Italy, and speak the Italian language, but in knowledge and refinement they are scarcely on a level with the middle ranks in England. The lower classes, like the continental Greeks, use the Rromaic language, but with a larger mixture of Italian words; and, like them, too, they are active, ingenious, adroit, loquacious, subtle, and intriguing. Physic and law are favourite professions, and the better order of lawyers and physicians, who have been educated in Italy, form the most intelligent part of society. The clergy are extremely numerous, but less informed, and inferior in respectability to the two former classes. They were very active in resisting some of the reforms attempted by the British. When Major du Bos-et introduced the culture of the potatoe in Cephalonia, they laboured to persuade the peasants, that this was the very apple with which the serpent tempted Adam and Eve in paradise. (Holland, 41.) The women, as in Greece, are almost entirely secluded from society, and are, of course, ignorant, superstitious, and feeble in their character. (Holland, Chap. i. ii.) In all that regards the intercourse of the sexes, much laxity of morals prevails, but the poor are less corrupted than the rich. Most of the nobility have mistresses, and the laws allow them to legitimate the issue of these connections by a subsequent marriage. A sort of agreement is not unfrequent, by which a young woman is made over by her parents, with her own consent, to her admirer at a stipulated sum. This species of concubinage, which frequently terminates in marriage when the girl is respectable and has children, is, on other occasions, the cause of much infidelity and unhappiness. (Williams, *Letters* xlvii. xlviii.) In the country the Greek dress is generally used, though with some modifications; but in the town the Italian dress prevails, as well as the

Ionian
Islands.

Italian fashions in the style of furniture, and in the modes of social intercourse. It was a leading object in the policy of the Venetians, indeed, to extinguish the national spirit of the Ionians, to deprive them of the means of education, and to brutalise their character by every method in their power, that they might convert them into passive instruments of their sovereign will. But, after three centuries of such policy, there can be no doubt, that the Venetians more by the odious nature of the innovations attempted than they gained in security by the result. (Audoucourt, Chap. ii. xii.)

Religion.

The attachment of the Ionians to the Greek religion, however, has effectually resisted the innovating spirit of their masters. The Catholic worship is tolerated, but the national faith has lost little of its influence upon the minds of the people. Each island has its patron saint, in the efficacy of whose intercession the people are taught to believe. The British authorities humour the popular superstition in this particular; and, in Corfu, the patents from the health office bear to be "in the name of God, and by the intercession of Saint Speridion." Ceremonies and processions, with fasts, frequent and severe, take the place of piety and good works. A ruffian, engaged in a project of assassination, has refused to taste animal food in the season of the fast. As in many other countries, the lower orders are comparatively strict in their religious observances, while indifference and infidelity are common among the higher classes. But, if religion is in a low state, it is not from the want of priests and churches, the number of which is out of all proportion to the number of inhabitants. The little island of Paxo, with 4000 inhabitants, has 36 churches (Williams); and Cerigo, with 9000 inhabitants, is said to have the incredible number of 260 churches, or chapels, and 165 priests. (Holland.) These swarms of priests are a sort of privileged mendicants. They are, in general, too illiterate to understand religion themselves, and, of course, they are incapable of teaching it to others. But as they derive their subsistence chiefly from fees for absolution, and from gifts and offerings, they find it necessary to support their influence, by filling the minds of those under their care with a thousand idle or pernicious superstitions. Besides the secular clergy, there are a number of regular religious in convents scattered over the islands, but of their number or condition we have seen no satisfactory account. (Holland, Chap. i. and Williams, *Letters* xlvii. xlviii.)

History.

The Ionian Islands make no considerable figure in ancient history. Cephalonia, Zante, Ithaca, and Santa Maura (then joined to the continent), formed part of the kingdom of Ulysses; and if we may judge of their condition, from the armament which their prince carried with him to the Trojan war, we should conclude that they were less populous and less improved than the continental parts of Greece. These islands, along with a part of the opposite continent, furnished only twelve ships; while the little island of Salamis, not one-twentieth part of the extent, sent as many. (*Iliad*, l. ii. 631.) They were then, as at this day, under

Ionian
Islands.

power of a number of petty chieftains; and it is a proof of the accuracy of Homer's geographical knowledge, that their relative numbers, as stated by Telemachus (*Odys.* l. xvi. 249), correspond tolerably well with the actual extent and importance of the islands, Cephalonia (Samus) having 24, Zante 20, and Ithaca 12. At a later period, the Corinthians planted colonies in Leucadia and Corcyra, and probably in some of the other islands over which they maintained some degree of authority. The Leucadians sent 800 men to fight the Persians at Platea, and the Cephallenians of Pale 200. (Herodotus, l. ix.) The Corcyreans, from their favourable situation, rapidly became strong by sea, and not only shook off their independence on the parent state, but committed depredations on the commerce of the other Grecian cities, till the Athenians, shortly after the battle of Marathon, attacked them and broke their naval strength. The jealousy between the Corcyreans and Corinthians, about forty-five years later, led to hostilities between the parties, in which the Athenians were drawn in to take the part of the former, and the extension of this petty quarrel at length produced the celebrated Peleponnesian war. The Corcyreans had 120 triremes when the contest began, and were the second naval power in Greece. (Thucydides, l. i. Xenophon, *Hist.* l. vi.) The Zacynthians also, who were a colony of Achæans, and the Cephallenians, were generally leagued with the Athenians, and afforded them assistance in the expedition against Syracuse. The Leucadians we find adhering to the Corinthians. (Thucydides, l. ii. iii. vii.) When the Spartans invaded Corcyra, about thirty years after this, the country is represented as richly cultivated, finely planted, and abounding in wealth and luxury. (Xenophon, *Hist.* l. vi.) Cerigo, from its situation, was almost always an appendage to Laconia. These islands, with the rest of Greece, at length fell under the dominion of the Macedonians. In the wars between Philip and the Etolians, however, we find the latter occasionally making use of the naval forces of the Cephallenians. (Polyb. l. iv. 6.) When the Romans established themselves in Greece, these isles, from the position between that country and Italy, were early occupied; and Corcyra is often mentioned as a station of their fleet in their subsequent wars. (Livy, l. xxiv. xxxii. xxxvi. xxxviii.) They continued to follow the fortunes of the Roman empire nearly to the latest period of its decline; and they suffered from the ravages of the Goths, Wallachians, and other barbarous tribes, till they fell into the hands of the Venetians, some of them in the twelfth, and others in the thirteenth century. This nation also conquered various maritime towns on the continent of Greece, of which, as well as of some of the islands, the Turks occasionally dispossessed them. The Venetians first acquired the Morea in 1417, and lost it finally in 1715. The Turks, at this latter period, took Cerigo, and besieged the city of Corfu; but the Venetians becoming masters at sea, regained Cerigo, repulsed the Turks from Corfu, and took several continental towns. The treaty of

Ionian Islands.

Campo Formio (October 1797), which annihilated the state of Venice, transferred to France the Ionian Islands, with their continental dependencies, consisting, at that time, of five seaport towns, Butrinto, Gomenitza, Parga, Prevesa, and Vonitza. When the invasion of Egypt led to hostilities between France and Turkey in 1798, Ali, Pasha of Albania, besieged and took Prevesa and the other continental towns, except Parga; and the islands having been reduced by the fleets of Russia and Turkey, were erected into an independent state, by a treaty between these powers, dated 21st March 1800. They were placed under the protection of the Porte, as its vassals, and were to pay it an annual sum of 75,000 piastres. (*Annual Register*, 1800. *State Papers*, p. 278.) The towns on the continent were ceded to the Porte, of four of which it obtained possession. But the inhabitants of Parga, dreading the merciless disposition of the Albanian Pasha, took up arms in their own defence, and, favoured by the strength of their position, repelled his assaults. A constitution was given to the republic in 1803, which it is unnecessary to describe, as it has since been superseded. It is sufficient to say, that it was drawn up by Russian ministers of state, ignorant of the circumstances of the islands, and contained such a specimen of republican principles, as might be expected from Muscovy. The war between Russia and the Porte in 1806 led to the occupation of the Ionian Islands by the former, and by a secret article of the treaty of Tilsit (June 1807), they were made over to France. The French, during their first occupation of the islands, had abolished the use of the Italian language in public acts, and re-established the Romaic. Connecting these possessions with his projects against Turkey, Napoleon was anxious to revive the national spirit of the Greeks. A Romaic newspaper was set on foot (and has been continued by the British); establishments for promoting scientific education were projected, and to crown these schemes by a piece of French extravagance, the reckoning by olympiads was introduced. These projects held out only a distant prospect of good, but the expence of the large military force stationed by the French in the islands was a real and immediate grievance. In 1810, a British force, under General Oswald, took possession of Zante, Cephalonia, Ithaca, and Cerigo, almost without opposition; and of Santa Maura after some resistance. Corfu and Paxo having garrisons too strong to be attacked, were merely subjected to a maritime blockade, which, however, could not be so rigorously enforced as to reduce them. They were surrendered to the British after the general peace in 1814. The Turkish government now renewed its claim to Parga, under the treaty of 1800, though that claim had been virtually set aside by subsequent circumstances. That government had entirely failed in affording the Ionian Islands the stipulated protection, since it had suffered first the Russians, and afterwards the French, to occupy them with a military force. It had been a party to subsequent treaties, by which this had been in substance annulled. The

original treaty bound the Turks to protect the Paraginites; and it was now obvious, from the fate of the other towns, and from the feelings of the inhabitants, that its surrender would be equivalent to a warrant for its destruction. Lastly, the British had no right to make over Parga to the Turks, for it was not reduced by our arms, but its inhabitants put themselves under our protection by a voluntary act, and upon the express condition that their town was to remain attached to the Ionian republic. From ignorance or inattention to these circumstances, however, the Congress of Vienna had resolved that Parga should be given up. And, in obedience to the mandate of this conclave of sovereigns, the soldiers of Ali took possession of the bare walls in June 1819; the inhabitants, amounting to 5000, having, to a man, emigrated to Paxo and the other islands, after receiving a very inadequate indemnity for the loss of their property.*

Ionian Islands.

The Ionian Islands, either as a separate state or General Republic, as a dependency of Great Britain, are of little importance. The interest felt in their fate is founded on classical associations, and on the means they are supposed to afford for restoring the Greeks to their existence as a nation. But, under the political system established in the islands, the hopes raised on the latter ground appear to us to be almost entirely chimerical. The Ionian Greeks must be enlightened and improved themselves before they can become useful auxiliaries in the work of enlightening and improving the rest of their countrymen, who are groaning under Turkish tyranny. To effect this change in their character, and to create and nourish a national spirit, three things are indispensable, with which their new constitution leaves them entirely unprovided—a system of national education, a free press, and a free government. The British ministry, in patronising a plan for erecting a university in the islands, has begun its operations at the wrong end. The first and most indispensable step is to increase the small number of schools at present in existence, till they are sufficiently numerous to afford common education to the whole population. A university may then be useful; but the Greeks can never be emancipated by giving a learned education to a few individuals, while the mass remain sunk in ignorance and superstition. On the other hand, when a moderate degree of knowledge is generally diffused, ardent spirits will emerge from the multitude, and rise to eminence by their native force, while their countrymen will then be better prepared to reap advantage from their exertions. At present a well informed Greek finds his acquisitions useless, and can only mourn over the hopeless humiliation of his country. Again, without a free press in their native language, the Greeks cannot receive that political instruction which is necessary to fit them for becoming once more a nation; knowledge cannot be rendered popular, nor of course useful; and a university will become a mere establishment of sinecures, or an engine for propagating corrupt and servile doctrines, worse than ignorance it-

Ionian
Islands
Ireland.

self. It is no solid objection that the Ionian Greeks are mere children in literature, and could not make a discreet use of the press. Feeble as their powers may be, they will continue children still, if they do not use them. Their own blunders will often be better instructors than the mature wisdom of others, if their minds are kept in a state of pupillage. With general education, and a free press, should be conjoined the invigorating spirit of a popular government—not a government bottomed on close corporations and privileged classes—but one broadly republican in its forms and spirit. Whatever may be the defects of such a government, it is calculated, beyond all other human inventions, to call forth the energies of man. It was this inspiring power that carried forward the ancient Athenians in their brilliant career of improvement and glory; that raised the Italian and Dutch republics to sudden wealth and power; and that is now giving a new aspect to the vast continent of North America. The people are ignorant and disorderly, but probably not more so than the Athenians in the time of Solon, or the Italians in the thirteenth century, who were, nevertheless, found capable of supporting republican institutions. The errors into which their ignorance might have led them, would most probably have soon cured themselves. And, at any rate, the Ionians are in that precise situation, which would have divested such institutions of the dangers usually supposed to attend them. The natural influence of the British Government, as the protecting power, would have moderated the violence of factions, and preserved the government stable amidst their struggles. Had a free, active, and enlightened community been raised up in these islands, speaking the language of Greece, and almost in contact with the country, the emancipation of the continental Greeks would not only have been secured, but so much light would have been diffused among them, and such a good model set before them, that they would have been in a condition to make a wise and safe use of their independence, and step at once into the enjoyment of

a free constitution. As matters have been managed, however, it would be foolish to expect, that these islands will contribute in any degree to the liberation of the Greeks. Exclusive of the prerogatives of the High Commissioner, all power is vested in the nobles, who are universally described as the most worthless part of the population. Votes alone will command office, and the mass of the people who have no votes to give, though not expressly, will yet be substantially excluded from every place of trust and honour, and kept in the same state of vassalage as under the Venetians. Public burdens will naturally accumulate, because those who impose taxes have a separate interest from those who pay them; and abuses will multiply, because the nobles, hanging on the government for support, are gainers by a system of waste and profusion. A free press, which would have corrected some of these evils, has been jealously guarded against by the constitution; and as for the right of petition, in a government so constructed, it must be an empty name. In all probability, then, the Ionians will consider the Turkish practice of insurrection as the only effectual method of making known their grievances. Accordingly, since the new constitution was promulgated in 1817, we observe, by the public papers, that two attempts at insurrection have been made. But whether these have originated in the factious spirit of the nobles, or the discontents of the body of the people, has not been clearly explained. Yet though so little has been done for the people, the change has certainly been for their advantage. The administration of justice will no doubt be improved; the private wars and open rapine of the nobles restrained; and the powers taken from these persons, and conferred on the Commissioner, will be more beneficially exercised for the inhabitants at large. But a much more stable foundation would have been laid for good government, had the people been furnished with constitutional rights to protect themselves, even although they had not made a wise use of those rights in the first instance. (B.B.B.)

Ionian
Islands
Ireland.

I R E L A N D.

THE History of Ireland, down to the year 1789, is given in the article IRELAND in the *Encyclopædia*, and its subsequent history will be found under GREAT BRITAIN in this Supplement. In this article we shall confine our attention to the statistical and political state of the country.

CHAP. I.—STATISTICS.

*Divisions.—Face of the Country.—Soil.—Productions.—Climate.—Population.—Agriculture.—Manufactures.—Commerce.—Revenue.—Expenditure.—Debt.—Public Education and Charities.**

Ireland is situated between 6° and 10° 40' west longitude, and 51° 15' and 55° 13' north latitude. Its greatest length is 241 Irish, or 306 English

miles; and its greatest breadth 137 Irish, or 174 English miles. In consequence, however, of the deep indentations of the shore on the west coast, there is not a spot in the kingdom 50 miles distant from the sea.

From the latest accounts, it appears that its superficial contents are 19,436,000 English acres, or 30,370 square miles. Mr Wakefield, however, makes it contain 32,201 square miles, or 20,437,974 English acres. (Beaufort, 14.) Mr Pinkerton assigns to it only 27,451 square miles (Pinkerton, i. 211); but it would rather appear that his estimate is below the truth. (Wakefield, i. 4.)

This country is divided into four provinces, Ulster, Leinster, Connaught, Munster. Ulster, which is the most northerly province, contains 8375 square

Divisions.

Ireland, miles English, and comprises the following counties:

Counties.	Baronies.	Parishes.	Irish Acres.
Armagh, containing	5	20	181,450
Down,	8	60	348,550
Antrim,	8	77	387,200
Londonderry,	4	31	318,500
Donegal,	4	42	679,550
Tyrone,	4	35	463,700
Fermanagh,	8	18	283,450
Cavan,	7	30	301,000
Monaghan,	5	19	179,600

Total (Wakefield, I. }
12. et seq.) } 53 332 3,201,200

Leinster is the most easterly province, and adjoins the Irish Channel. It contains 7560 English square miles, which are divided into the following counties:

Counties.	Baronies.	Parishes.	Irish Acres.
Louth,	4	61	110,750
Meath,	12	147	327,900
Dublin,	6	107	142,030
Wicklow,	6	58	311,600
Wexford,	8	142	342,900
Kilkenny,	9	117	300,350
Carlow,	5	50	137,050
Queen's County,	8	50	235,300
King's County,	11	52	282,200
Westmeath,	12	62	231,550
Longford,	6	23	134,150
Total of Leinster,	97	992	2,792,550

Connaught, the most westerly province of Ireland, comprises 7191 square miles English, and comprehends the following counties:

Counties.	Baronies.	Parishes.	Irish Acres.
Galway,	16	116	989,950
Mayo,	9	68	790,600
Sligo,	6	89	247,150
Leitrim,	5	17	255,950
Roscommon,	6	56	346,650
Total of Connaught,	42	296	2,630,300

Munster, the southern province of Ireland, contains 9276 English square miles, and is divided into the following counties:

Counties.	Baronies.	Parishes.	Irish Acres.
Cork,	16	269	2,048,800
Kerry,	8	83	647,650
Clare,	9	79	476,200
Limerick,	9	135	386,750
Tipperary,	10	186	554,950
Waterford,	7	74	262,800
Total of Munster,	59	816	3,377,150

Ireland, therefore, contains in its four provinces, Ireland

Provinces.	Counties.	Baronies.	Parishes.	Irish Acres.
Ulster,	9	53	332	3,201,200
Leinster,	12	97	992	2,792,550
Connaught,	5	42	296	2,630,300
Munster,	6	59	816	3,377,150
Total,	32	291	2416	11,981,200

The most elevated ground is to be found in the Bog Face of the of Allan. Its height above the Sea does not exceed Country. 270 feet; yet, from this ridge, the waters of the rivers run to the different seas. This elevated ground is connected with the principal mountains of Ireland, diverging in the north from the hills of Tyrone, and leading in the south to those of Sleeve Bloom and the Galtees. The face of the country affords a pleasing variety of surface, consisting in some parts of rich and fertile plains, in others of little hills and acclivities, which succeed one another in frequent succession. The chains of mountains are neither numerous nor considerable; the most remarkable are the Kerry Mountains, those of Wicklow, the Sleeve Bloom Chain between the King's and Queen's County, and the mountains of Mourne in the south of the province of Ulster. The following is a table of some of the most remarkable heights in the kingdom. (Wakefield, I. 10.)

	Feet above the Sea.
Macgillicuddy's Reeks, Killarney,	3695
Mangerton ditto,	2693
Stubb Donard, county Down,	2809
Nepbin, Mayo,	2630
Crow	2660

The numerous rivers and deeply indented bays of Ireland have given it greater facilities for internal navigation than almost any country in Europe. The Shannon is its largest stream, which rises in the northern part of Connaught, and after a course of 170 miles, during which it expands into six lakes, flows into the Atlantic Ocean between the counties of Clare and Kerry.—It is navigable by large vessels as far as Limerick.—The Bandon, another considerable river, rises in the mountains of Carberry, and running to the east, finally arrives at Kinsale, after many beautiful reaches of river scenery. The Lee rises in a lake to the west of Muskerry, and falls into the sea about 15 miles below Cork. The Blackwater rises in a bog near Castle Island, in the county of Kerry, and after a course of 60 miles, falls into the sea at Youghall. The Liffey rises about 10 miles to the south-west of Dublin, and after a winding course of 50 miles, falls into the bay of the same name. The Boyne rises in King's County, and after being joined by various streams, falls into the sea about two miles below Drogheda. The Sure rises at the foot of the Banduff Mountains, in the county of Tipperary, and falls into the sea at Waterford. The Barrow rises in King's County, and, uniting with the Sure, forms the right arm of Wa-

Ireland. terford Haven. The Slane rises in the county of Wicklow, and falls into a bay a little below the town of Wexford; and the Bann rises in the mountains of Down, and flows with impetuous force into the sea a little below Coleraine.

Lakes.

The most considerable lakes of Ireland are Loch Neagh, Loch Earne, Loch Corrib, and the Lakes of Killarney. The first of these, Loch Neagh, is very extensive, covering 58,000 acres; but it exhibits no remarkable beauty in its shores, the adjacent country being, for the most part, flat, though well wooded. Many gentlemen's seats of great antiquity and beauty adorn its banks. Loch Earne, in the county of Fermanagh, consists, properly speaking, of two lakes, which unite in the vicinity of Inniskillen. The first, or uppermost, is 20, the second 15 miles long. Its greatest breadth is 12 miles. The banks of this lake, though sometimes rising to a considerable elevation, are rather distinguished by their amenity and softness, than by their sublime features. The adjacent country is covered with little knolls, or small hills, of 50 or 60 feet in height, which, being generally ornamented by wood, present a most agreeable appearance; and the numerous islands in the lakes themselves, amounting to 300 in number, are formed by the same prominences in the soil rising above the surface of the water. Loch Corrib, in the province of Connaught, is 20 miles long, but its medium breadth is only four miles.—Its banks exhibit nothing remarkable. The Lakes of Killarney form the glory of Irish scenery, and constitute one of the principal inducements to foreigners to visit that island.—They are three in number; the lower lake, consisting of 3000 acres, lies on the northern side of Macgillicuddy's Reeks; the middle lake, consisting of 640 acres, lies at the foot of Turk Mountain, and from thence the traveller is led by a winding stream of exquisite beauty to the upper lake, which covers 720 acres, and lies in the very centre of the Kerry Mountains. To those who have visited the Swiss and Italian lakes, it is hardly necessary to observe, that no scenery here at all approaches what they have met with there; but the Lakes of Killarney may well bear a comparison with the finest of the Scotch and English lakes. The range of Macgillicuddy's Reeks presents a splendid series of Alpine peaks, which form the back ground of almost all the scenery on the lakes; and the moist climate and mild winters of Ireland have given a verdure and richness to the arbutus and other shrubs which clothe the rocks and islands that rise out of the water, unlike any thing else in the British empire. Mucross Abbey and Park form a most interesting addition to the lower lake, and the Island of Innisfallen, both from the luxuriance of the ivy with which it abounds, and the romantic forms of the aged trees with which it is shaded, excels any island that is to be met with in any lake in Europe.

Canals.

The interior of Ireland is intersected by a variety of canals. The *Grand Canal*, which was originally begun by individuals, and subsequently completed after the Union by government, unites Dublin with Shannon harbour, while another branch proceeds to Athy, where it joins the Barrow. This canal inter-

sects the Bog of Allan, and is of great service in supplying the capital with fuel. The *Royal Canal* begins at Glassmanogree, in the county of Dublin, and extends to Coolnahay, beyond Mullingar. It is of great service in the carriage of loam and turf. The *Newry Canal* runs along the Southern boundary of the county of Down; it is cut from Carlingford Bay, and joining the Newry water, embraces the upper Banco at Porto Down. In this way the navigation is continued to Loch Neagh, while a branch leads off to the Tyrone coaleries. This canal admits vessels of sixty tons burden, and is one of the most useful in the kingdom. Generally speaking, however, the attempts which have been made to improve the internal navigation of Ireland have met with very bad success, and many companies, as well as individuals, have been ruined in the attempt;—a fact which demonstrates that, to effect such undertakings, the interposition of government is, in the present circumstances of the country, indispensable. (Wakefield, I. 651; Young II. 66.) The Grand and Royal Canals have cost £2,000,000 Sterling; and the only one which now yields a profitable return is the Newry Canal. (*Ibid.*) These facts lead to a suspicion, either that money laid out in such undertakings is misspent, until the state of the country leads to a much greater consumption of bulky articles, or that the vicinity of every part of the island to the sea, or some of its deep indentions, renders such undertakings less advantageous here than in other countries. This matter is well worthy of deliberate consideration, in determining upon the policy of continuing any farther grants of the public money to the improvement of the country in this particular. (Wakefield, I. 650.)

Ireland.

The harbours of Ireland are among its most remarkable natural advantages. Fourteen harbours for ships of the line, seventeen for frigates, and thirty-six for coasting vessels, besides twenty good roads, are to be found on the different coasts of the island. Bantry Bay is one of the most secure and capacious harbours in the world, being nine leagues long and two broad, surrounded by lofty rocky shores. In the middle of the haven is Bear Island, six miles long; and between it and the northern shore is Bear Haven, fit for the largest fleets. The Cove of Cork is celebrated in the naval world for the extent and depth of its water. The entrance is about a mile in breadth, after passing which the sea expands into a fine basin, capable of containing the whole navy of England. In the centre are three islands, which break the force of the sea, and serve as a shelter to the shipping. Crookhaven, in the county of Cork, is also an admirable harbour, landlocked on every side, with a spacious bay, an easy outlet, and good anchorage in three fathoms at low water. Dingle Harbour, on the west coast, is a most eligible shelter for shipping, six leagues in length, and four in breadth, sheltered from all winds, and with 30 feet water. In Lough Carlingford is to be found a large anchorage, with depth of water sufficient for the largest ships; but, unfortunately, several dangerous rocks obstruct the entrance to the harbour. Belfast Loch, also, is of great utility in a commercial

Ireland. point of view; and, on the west coast of the island, Galway Bay, Butterby Bay, Conichin Bay, and Sligo Bay, all afford most remarkable facilities for commerce. Lough Swilly, in the county of Donnegal, is one of the noblest natural harbours in Europe, twenty miles long and two broad, with good anchorage, and deep water, fit for the reception of the largest fleets. Lough Foyle is a large haven, with twelve fathom water, and capable of affording shelter to vessels of any description. Besides these, the island possesses a vast number of other natural harbours, which would be eagerly improved in other countries, less bountifully supplied by nature.

Giant's Causeway.

The *Giant's Causeway* is one of the greatest natural curiosities of Ireland. It is situated on the north-eastern extremity of the island, where the coast rises to the height of 700 or 800 feet above the sea. The cliffs there are upwards of 400 feet in height; and at their feet lies the causeway, composed of the summits of basaltic columns, so nicely wedged, as to form a solid impervious mass of natural masonry, with an irregular and broken surface. This extraordinary pavement extends for above a mile along the coast. The sublime features of this spot rival its geological interest; and in no part of the empire is a nobler cliff to be seen than is presented by Cape Pleskin, which overhangs the ocean with a precipice 374 feet in height. Adjoining to this natural curiosity is Fairhead, the north-east promontory of Ireland, and elevated above 500 feet above the sea. It presents a vast mass of rude columnary stones, many of them exceeding 200 feet in length; and at the feet of these gigantic columns lies a wild waste of natural ruins, of an enormous size, which, in the course of ages, have been tumbled down from their foundations by storms, or other convulsions of nature. A savage wildness characterises this great promontory, at the foot of which the ocean rages with uncommon fury.

The Atlantic Ocean breaks with inconceivable violence upon the western shores of Ireland; and, to this cause, the extraordinary indented line of the coast is to be attributed. Along the greater part of this coast, the sea appears to be gaining on the land; and, in many places, particularly in the peninsula of Rossgall, in the county of Donnegal, large tracts have been overwhelmed by sand. (Hamilton's *Memoir*, Vol. VI. *Irish Trans.*)

Soil.

The soil of Ireland is, generally speaking, a fertile loam, with a rocky substratum; although there are many exceptions to this description, and many varieties. Generally speaking, it is rather shallow; to which cause the frequent appearance of rocks near the surface, or at no considerable depth, is to be attributed. It possesses a much greater proportion of fertile land, in proportion to its extent, than either England or Scotland, as will be seen from the following table. (*Parliamentary Reports*, 1813-14.)

	English Acres.
Total extent of surface,	30,437,974
Total extent of bog and mountain,	2,330,000
Remain of arable ground,	18,107,974

VOL. V. PART I.

Not only is the island blessed with this extent of arable ground, but it is almost all of such a quality as to yield luxuriant crops, with little or no cultivation. Sand does not exist except on the seashore. Tenacious clay is unknown, at least near the surface. Great part of the land of Ireland throws up a luxuriant herbage, without any depth of soil, or any skill on the part of the husbandman. The county of Meath, in particular, is distinguished by the richness and fertility of its soil; and, in Limerick and Tipperary, there is a dark friable sandy loam, which, if preserved in a clean state, will yield crops of corn several years in succession. It is equally well adapted for grazing as for arable crops, and seldom experiences either a winter too wet, or a summer too dry. The vales, in many of the bleakest parts of the kingdom, as Donnegal and Tyrone, are remarkable for their richness of soil and luxuriance of vegetation, which may be often accounted for by the deposition of the calcareous soil, washed down by the rains of winter, which spreads the richest manure over the soil below, without subjecting the farmer to any labour. (Wakefield, 1. 79, 80.)

The bogs, or peat mosses, of Ireland, form a remarkable feature of the country, and have been proved by the Parliamentary Commissioners to be of great extent. They estimate the whole bogs of the kingdom at

	2,330,000 Acres Eng.
Of these are flat red bog,	1,576,000'
Mountain,	1,255,000

These bogs, for the most part, lie together. In form, they resemble a great broad belt, drawn across the centre of Ireland, with its narrowest end nearest to the capital, and gradually extending in breadth as it approaches the Western Ocean. The Bog of Allan is not one contiguous morass, but this name is indiscriminately applied to a great number of bogs, detached from each other, and often divided by ridges of dry country. These bogs are not, in general, level, but most commonly of an uneven surface, swelling into hills, and divided by valleys, which affords the greatest facility to their being drained and improved. In many places, particularly in the district of Allan, the rivulets which these inequalities of surface produce have worn their channels through the substance of the bog down to the clay or limestone gravel beneath; dividing the bog into distinct masses, and presenting, in themselves, the most proper situations for the main drains, and which, with the assistance of art, may be rendered effectual for that purpose. (*Fourth Report of the Parliamentary Commissioners*, 1813-14.)

The two circumstances which the Commissioners point out, as affording the principal inducements to attempt the improvement of the Irish bogs, are the elevation at which they are all placed above the sea, and the uneven surface which they almost uniformly exhibit. The following table will show, in one view, the elevation above the sea of the principal bogs to which their attention has been directed:

N

Ireland.

	Highest Point.	Lowest.	Greatest Depth.	Least.
Lullymere Bog,	256	214		
Timahoe Bog,	289	232		
Bog of Mounds,	296	254		
Clare Bog,	298	255		
Bogs on west of Shannon,	76	29	43	21
Bogs of Longford and Leitrim,	114	30	43	30
				aver.
District of Boyne Bogs,	336	218	40	22
Westward of Brusna,	274	114	44	30
Southward of do.	310	111	45	22
Districts of Inny and Lough-ree,	253	176	47	30

From these data, the practicability of draining the bogs of Ireland is very obvious; and, as far as the estimate of the engineers can be depended on, the expence will be amply repaid by the quantity of useful land recovered. The estimate for draining the eastern district of the Bog of Allan is L.147,052, and the quantity of land which would be gained is 36,430 English acres; the outlay upon which would be more than covered by the first year's produce.

Woods.

Like all other countries of Europe, this island was formerly clothed with extensive forests, which are now no longer to be met with. Fermanagh is better clothed with timber than any other county in the kingdom; and oak abounds upon the mountains of Killarney, and in the glens of Wicklow. One remarkable feature of the country, however, strongly indicative of the effects of a non-resident body of landed proprietors, is, that new plantations are hardly ever to be met with. In the county of Clare, there are only 780 acres of plantation, and in Kilkenny 1800; quantities much inferior to what many Scotch proprietors possess on their own estates. (Wakefield, I. 561.) A traveller may go from the Giant's Causeway to Killarney, and from Cork to Londonderry, without meeting as many young woods as there are counties on his road.

Minerals.

This island rests for the most part on a bed of granite. It abounds in the neighbourhood of Dublin, and in some parts of the county of Kilkenny. It is also found emerging from beneath the basalt of Sleeve Gallen in the county of Derry.

Limestone.

Limestone is met with in great abundance in various parts of Ireland; indeed, in all the counties except Wexford, Wicklow, Tyrone, and Antrim. The rivers Barrow, Lee, Bride, Kenmare, and Blackwater, form the boundary of the limestone districts in their respective counties. The varieties of this mineral, which are found in Kilkenny and in the county of Derry are susceptible of a very high polish, and hence well adapted for the purposes of building and ornamental architecture. In the Cave of Dunmore, in the former county, alabaster is found in large quantities. The basalt district of country is very extensive, reaching from the estuary of Carrickfergus to Loch Foyle, and extending inland to the

northern shore of Loch Neagh. It rises to a great height at the north-western extremity of the island, forming the lofty headlands of Pleskin, Fairhead, and Bengore, already noticed.

Coal is met with in various parts of the island. In Coal Ulster there are two coal mines worked, one in Antrim at Ballywater, and the other near Dunganon in Tyrone. Coaleries are wrought near Arigna, in the county of Leitrim. The province of Leinster is abundantly supplied with this mineral. The coalery which is worked near Castle Coomer, at Doonane, in Queen's County, produces annually 40,000 tons. It costs 10s. a-ton to extract it, and gives employment to 600 persons. At Kilkenny also coal is worked. A continuation of the Castle Coomer coal is wrought in Tipperary; and in the barony of Duhallow, and the county of Cork, it has been discovered. With this exception, however, the southern parts of the island are destitute of this valuable mineral.

Pieces of native gold have been discovered in the bed of a stream flowing down from Crowbane, in the county of Wicklow; but it does not bear the expence of working. Silver was formerly extracted to a considerable extent from the lead mines in Antrim, Sligo, and Tipperary, but the works were destroyed in the insurrection in the time of Charles I. Copper is found at Ross Island in Killarney, at Mucruss, Crowbase, and Bullymustaglo, in the county of Wicklow, and in some parts of the counties of Cork, Meath, Waterford, and Dublin; but at present no mine of this mineral is wrought in the island. Lead is found at Enniscorthen in Wexford; near Glendalough, in Wicklow; and in the county of Donnegal, but not above one or two of these various mines are wrought. The most valuable of these metals, iron, is very plentiful in various parts of the island, and, in the seventeenth century, it was wrought to a great extent; but at present they are neglected. Grey ore of manganese has been found in the peninsula of Howth, and in various parts of Kilkenny, Mayo, and other counties. Fragments of tin-stone occur in the gold mine of Wicklow; and porcelain earth, equal to the finest in Cornwall, has been found in the same county.

The climate of Ireland is considerably more mild than that of England, and the southern and western part of the island greatly more so than the northern. The difference in this respect, indeed, is greater than can be explained by the difference of latitude, and is probably owing to the immediate vicinity of the Western Ocean. On the mountains of Kerry, and in Bantry Bay, the arbutus and some other shrubs grow in great luxuriance, which are not to be met with again till the traveller reaches the south of the Alps. The snow in these parts of the island seldom lies for any time, and frost hardly ever continues beyond a few days, and while it lasts it is by no means intense. The mildness and humidity of the atmosphere produce a luxuriance and rapidity of growth in vegetation, to which no other part of the empire can afford any parallel; and this appears in the most remarkable manner in the ivy and other evergreens, with which the kingdom abounds. These are not

Ireland. only much more plentiful, but far more luxuriant, and of much quicker growth, than in the most favoured parts of Great Britain. To those who are accustomed to the dry weather of this island, the continued rains of the south and west of Ireland are extremely disagreeable; but it is to this peculiarity in their climate, that the Irish have to attribute the richness of their pasturage, an advantage which, coupled with the remarkable dryness and friability of the soil, points, in an unequivocal manner, to a rotation of crops, in which grazing should occupy a principal place.

The following table exhibits the mean temperature of different places in Ireland, in the interior and on the sea coast, taken from very accurate observations. (Wakefield, I. 193, 199, 206, 218.)

	Latitude	Mean Temp.
Mean temperature of north coast, near Bally-castle,	55° 12'	48° 0'
Do. of Ennisor, west coast,	54 48	46 6
Do. of the vicinity of Dublin,	53 20	49 4
Do. of coast of Cork,	51 54	51 2
Do. of neighbourhood of Londonderry, 100 feet above the sea,	53 0	46 9
Do. near Armagh, 68 feet above the sea,	54 20	47 5
Do. of neighbourhood of Tullamore, 206 feet above the sea,	53 12	48 0
Do. of the city of Londonderry,	55 0	47 6 to 49°
Do. of Dublin,	53 21	50 0 to 52
Do. of Cork,	51 54	52 5 to 53

It would appear that the climate of Ireland has for some years past undergone a progressive alteration for the better. (*Ibid* I. 214.) The following table exhibits the changes in this respect, which have taken place within the last twenty years:

State of the Thermometer at Dublin and Belfast, from 1792 to 1804.

DUBLIN.

Years.	Greatest.	Least.	Mean.
1792,	77° 0'	19° 5'	50.509

1800	29.226	1743	39.3		
1801	32.197				
Average, 31.118					

At Cork, and generally over the south of Ireland, it appears that the winds blow three-fourths of the year from the west and south-west. (Smiles's *Survey of Cork*.)

An account of the actual population of Ireland, drawn from a survey by Government, is a great desideratum in the statistics of the country. The following table will show with what rapidity the numbers of the people have increased within the last 50 years. (Wakefield, II. 712.)

	Souls.
In 1754 Ireland contained	2,372,634.
1767	2,544,276.
1785	2,845,932.
1791	4,206,612.

Ireland.

Since that period a very great increase has unquestionably taken place. The present population does not probably fall much short of 5,500,000 (Newenham, 41.)

Without pretending to any accuracy of detail, the following may be considered as an approximation to the population of its principal cities, according to the most authentic accounts which can be collected. (Wakefield, II. 712-20.)

1. Dublin,	167,899.
2. Cork,	90,000.
3. Limerick,	60,000.
4. Waterford,	40,000.
5. Belfast,	22,095.
6. Drogheda,	15,000.
7. Kilkenny,	14,975.
8. Londonderry,	13,635.
9. Kinsale,	8150.
10. Wexford,	5922.
11. Colerain,	5000.
12. Lisburn,	5000.

Freehold-
ers

The number of *freeholders* in Ireland is very great. They are, for the most part, tenants of the landed proprietors, possessing a life interest in their little farm, so as to entitle them to vote at elections. The following table* of the number of freeholders, most of whom are not worth L.10, will be not a little surprising to the English reader:

Counties.	40s.	L.20.	L.50.

AGRICULTURE.

The Agriculture of Ireland is, generally speaking, in a very backward state. With a few exceptions, such as the county of Meath, and some other well cultivated districts, the farmers are destitute of capital, and labour small crops, which they hold of middlemen interposed between the and the landlord. The fact that the landlord never, in Ireland, lays out any thing upon repairs or buildings, coupled with the general inability of the farmer to do either in a substantial manner, is very significant as to the state of agriculture. (Tighe's *Survey of Kilkenny*, 412; Wakefield, I. 244.) The leases are generally of long endurance; three lives or 31 years is a common rate. But the worst features of the rural economy of this island are the entire want of capital in the farmers, and the complete indifference of the landlord to the character, wealth, or industry, of his tenant. "Capital," says Mr Wakefield, "is considered of so little importance in Ireland, that advertisements constantly appear in the newspapers, in which it is stated, that the preference will certainly be given to the highest bidder. Bargains are constantly made with a beggar, as a new tenant, if he offers more rent, invariably turns out the old one, however industrious. Even if the unfortunate wretch has a little ready cash to begin with, it only serves, in 99 cases out of 100, as a temptation to the landlord, who, when the fact becomes known to him, finds means to obtain it under the name of a fine for possession." (Vol. I. p. 587.) Regard to present gain, without the least attention to the future, constitutes the principal object of the Irish landlord. (*Ibid.* I. 304.)

The rent of land in Ireland from these causes, Rent coupled with the excessive competition of the peasantry for small farms, as their only means of subsistence, has risen to a great height. (Townsend's *Cork*, 218; Wakefield, I. 582.)

The following table exhibits the average rent in the different counties, as they were taken by Mr Wakefield in 1810, distinguishing the rent for cultivated area from that of the total area:

* This table shows an aggregate of 184,492 freeholders voting on freeholds of 40s. value.

And calculating the difference between the green acres and total area at one-fourth (according to Mr Arrowsmith's opinion), this will give L.1, 7s. 1d. as the average rent of the total area of the island. This, upon 12,722,615 Irish acres, gives L.17,228,540, as the total rental of the island, in Irish money (Wakefield, I. 805); or, upon 20,437,974 English acres, yields an average of about 17s. per English acre.

The capital laid out in the improvement of the soil is extremely small when compared with that employed in the neighbouring kingdoms of England and Scotland. In 1799, Mr Young calculated that, converting Irish acres into English, it would require an outlay of L.5 an acre to place Ireland on a footing with England in this respect. The whole amount, therefore, of the sum required would be L.88,341,186. (Young's *Irish Tour*, II. 9.) From the change in the value of money, Mr Wakefield has since calculated that the sum required to effect such a change would be L.120,000,000, independently altogether of the capital which the British agriculturist brings to his farm in order to carry on the cultivation of the land. When it is considered how little capital is thus sunk in the Irish soil, and recollected that the average rent of England is only 20s. an acre, even under the superior mode of cultivation which

is there pursued, it is obvious how much the proportion of the produce of the soil in Ireland, which goes to the landlord, has encroached on what should be left as a remuneration to the farmer. (Wakefield, I. 585.)

The price of land varies in different parts of Ireland. In the neighbourhood of Belfast, and thence to Armagh, it brings thirty years' purchase; in the greatest part of the island, it does not exceed twenty, and, in the richest districts, it may often be bought for sixteen or eighteen. The exposure of landed estates to public sale takes place very seldom, which is perhaps one cause of their not bringing so high a price as they would otherwise do. (*Ibid.* I. 807.)

The whole country is classed by Mr Wakefield Agricultural Districts. into nine agricultural divisions, in each of which the mode of culture is somewhat different from what it is in the others. The first district comprehends the flat parts of Antrim; the eastern side of Tyrone, Down, Armagh, Monaghan, and Cavan. Throughout this district, the farms are extremely small, and the land is generally dug with the spade. Potatoes, flax, and oats, are the crops usually cultivated, and these are grown till the land is exhausted, and suffered to "lie at rest," as they term it, till its strength is recruited by the cow, the goat, two or three sheep, and the poultry lying upon it, for some years. The ploughs used in this district are of the rudest structure, and perform their work in the most slovenly manner. Three or four neighbours unite their strength to each plough, every one bringing his horse, his bullock, or his cow. All the other operations of agriculture are performed in an equally slovenly manner. The little wheat that is raised is "lashed," as they call it, that is, the grain is knocked out by striking the sheaf across a beam placed above a cloth, which, however, is afterwards thrashed with a flail. This operation of thrashing usually takes place in the highway, and it is dressed by letting it fall from a kind of sieve which, during a pretty strong wind, is held breast high by a woman. Many cottars in this district have a cabin with no land attached to it. They hire an acre or two, for grass or potatoe land, from some cottar in their vicinity. The custom of hiring labourers is unknown, the neighbours all assisting each other in their more considerable occupations, such as sowing, reaping. The dwellings here are miserably small; often too small to contain the numerous families that issue from their doors. Land is everywhere divided into the most minute portions. (Wakefield, I. 363; Du-bourdieu's *Down*, 39.)

Under the second district may be comprised the northern part of Antrim, Londonderry, the north and west of Tyrone, and the whole of Donnegal. Agriculture here is in a worse state than in the preceding district. There is no clover, and hardly any wheat. Clover is unknown, and the only mill for the preparation of grain is in Derry. (*Ibid.* I. 372.)

The third district comprehends the northern parts of Fermanagh. Here the farms are much larger than in the former, and the agricultural system pursued far superior. They plant potatoes on

Ireland. a lea, twice reversing the lands, and the course is flax, oats, and weeds. Some wheat is grown, but oats is still the prevalent crop. In the neighbourhood of Enniskillen, the farmers are so rich as to be able to eat butcher meat daily and drink wine. (Wakefield, I. 379.)

The fourth district comprehends Sligo, Mayo, Galway, Clare, and parts of Roscommon, and Longford. In some parts of this district the spade culture is pursued; but, in general, the land is cultivated by a plough drawn by four horses abreast. In Roscommon, the old custom of yoking the horses by the tail is still continued, although, so early as 1634, an act of Parliament was passed against this absurd practice. (*Life of the Duke of Ormond*, I. 79.) Oats are chiefly raised in this district, and, along the coast, barley is cultivated. A large portion of the rent depends on the illegal distilleries, and much of the district is let on lease to several persons jointly, according to the village system. (Wakefield, I. 381.)

In the fifth district, which comprehends Limerick, Kerry, the south side and northern part of Cork, and the county of Waterford, cultivation is in a very rude state; little corn is grown here, with the exception of the southern part of Cork. Land is extremely divided, and the farms very small. The greater part is a grazing country. (*Ibid.* I. 387.)

The sixth district includes the southern parts of Cork. The spade culture is here almost universal, and the farms unusually small. Hogs constitute the main support of the poor. (Townsend's *Cork*, 194.)

Ireland. The seventh district includes part of Tipperary, with Queen's County and King's County. The best farming in Ireland is observable in this district; a systematic course of husbandry being pursued, by which the land is kept in good heart. Oxen and horses are used in the plough, and hedge-rows and good wheat fallows are to be seen. Near Roseria the cultivation of turnips is followed, and they succeed well. Ninety acres is considered a large farm. Leases are generally for three lives. (Wakefield, I. 398.)

The eighth district comprises Wexford and a part of Wicklow. Beans are here sometimes introduced into cultivation, but they are sown broad-cast, and never hoed. The mode of ploughing is very awkward; one man holds the plough, another leads the horse, and a third sits on it to keep it down. Notwithstanding this rude culture, however, the rents are enormous. (*Ibid.* I. 407.)

The ninth district comprehends the northern part of Kilkenny, Kildare, the cultivated parts of West Meath, Meath, and Lowth. Wheat here enters into the system of culture, but the preparatory fallows are very bad. Clover has been introduced into the district, but under the bad system of sowing it upon land exhausted, and covered by weeds. Farms are large, and the mode of culture similar to what is pursued in England, though the details are executed in a much more slovenly manner. (*Ibid.* I. 413.)

The following table exhibits, at one view, the produce of these different districts, according to the mode of cultivation at present adopted. The seed and produce is given in pounds Avoirdupois:

DISTRICTS.	WHEAT.		BEAR.		BARLEY.		OATS.		POTATOES.		FLAX.

General Observations on the Husbandry. The implements of husbandry used in Ireland are all of the rudest construction. The plough, the spade, the flail, the carr, all equally partake of imperfections and defects. The fallows are not well attended to; three ploughings are usually deemed sufficient, and, from the imperfection of the plough, the ground at the end is generally full of weeds. Trenching land is very general; they form it into beds, and shovel out a deep trench between them, throwing up the earth. The expense of this

operation is about 8s. an acre. Wheat, as will be seen from the preceding details, is not by any means generally cultivated. It is unknown in Monaghan, Tyrone, Derry, Donnegal, Sligo, Mayo, Leitrim, and Cavan, though it is grown to a considerable extent in Kilkenny, Carlow, Dublin, Meath, Louth, and parts of Limerick, Tipperary, Clare, and Cork. It is generally sown after potatoes or fallow. The Irish wheat is, for the most part, coarse and of inferior quality, and does not yield so much saccha-

Ireland. rine matter by 20 per cent. as the English. (Wakefield, I. 429, 442.)

Barley is more generally cultivated than wheat, and it is generally sown after potatoes. Oats, however, constitute the species of grain most extensively raised; it is calculated, that throughout the whole kingdom, there are ten acres of oats sown for one of any other species of corn. The Irish oats, however, are decidedly inferior to the English. The potatoes of Ireland have long been celebrated, both on account of their quantity and excellent qualities. They are cultivated on every species of soil, either in drills or lazy beds. Potatoe land lets from L.6, 6s. to L.10, 10s. per acre; and the expence of culture, including rent, varies from L.13 to L.16 per acre. The produce is from 800 stone to 1000 stone the acre, at twenty-one pounds to the stone; that is, from 16,800 to 21,000 pounds. (*Ibid.* I. 450.)

The indigenous grasses of Ireland are not of any peculiar excellence. Notwithstanding all that has been said of the *forin grass*, its excellence and utility may be called in question. Their hay is seldom from seed, generally consisting of the spontaneous produce of the soil. Clover is almost unknown. Mr Newenham calculates that there are not 5000 acres under this crop in the whole island. (Newenham, 314; Wakefield, I. 467.) There are few living hedges in Ireland; in the level stone districts, stone walls, and, in other places, turf-banks are the usual fences.

The dairy is the most extensive and the best managed part of Irish husbandry. Kerry, Cork, Waterford, Carlow, Meath, West Meath, Longford, and Fermanagh, as well as the mountains of Leitrim and Sligo, are principally occupied by dairy farms. Butter is the chief produce. The average number of cows on a dairy farm is thirty or forty; three acres of land, of middling quality, are deemed necessary for the subsistence of each cow. The average produce of a cow is eight quarts in twenty-four hours in summer, and five in winter; four good milkers will yield half a *cwt.* of butter in a week. The best butter is made in Carlow; the worst in Limerick and Meath. Generally speaking, the Irish are very clean in making this article, and it is exported to England, the East and West Indies, and Portugal. (Wakefield, I. 325, *et seq.*) The grazing of Ireland is not, as in England, a part of the regular rotation of crops, but is carried on in a country exclusively devoted to the breeding of cattle like the Highlands of Scotland. Great tracts of the country also are devoted to the grazing of sheep. Roscommon, Galway, Clare, Limerick, and Tipperary, are the chief breeding counties for sheep; and Galway, Clare, Roscommon, Tipperary, and Meath, are the places where they are fattened. The sheep are of the long-woolled kind, and very large; they are never kept in sheep-folds, and hardly ever fed on turnips; which is chiefly owing to the very limited demand for mutton among the labouring people. (*Ibid.* I. 341.)

Agricultural Exports. The Agricultural Exports of Ireland have increased at a very rapid rate within the last forty

years, owing chiefly to the great demand and near vicinity of England.—We have given a view of the Irish exports of oats and oatmeal, wheat and wheat flour, and of all other kinds of grain, in the tables contained in our article on the CORN LAWS AND TRADE, particularly table eleventh, to which we beg to refer the reader.

The export of butter to England and Scotland has, of late years, been very great.

Year ending	England. Cwts.	Scotland. Cwts.	Total.

MANUFACTURES.

Linen Manufacture.

The manufactures of Ireland are now very considerable, particularly the linen manufacture. This great and staple branch of Irish industry was established by the Duke of Ormond, in 1669; and, in the beginning of the following century, Parliament took it under its protection, and voted considerable sums of money for its support. At the same period, a Board was established, which has since exerted itself most vigorously for its encouragement. It enhances the value of this manufacture to the Irish population, that the raw material of which it is composed is raised almost entirely within the island. It would appear that the number of acres under flax in 1810 was little short of 100,000, which, at 30 stone an acre, and 10s. 6d. the stone, will give an annual produce of the raw material worth L.1,500,000. (Wakefield, I. 683.)

Spinning by the hand was universal till the commencement of the present century; and, though the use of machinery has since been introduced, yet it is by no means invariably followed, in consequence of the very low rate of wages at which the manufacturers can get spinning performed by the wives and daughters of the labouring population. The Irish women have long been celebrated for their skill in this department. The earnings of the weavers depend on their industry, and the fineness of the materials on which they work. The average earnings of a linen weaver may be estimated at 7s. a-week. Their looms cost from four to five guineas, but many houses will hold three looms. The weavers estimate that, when working themselves, they can make a web a-week, and a web is, at an average, worth 10s.

The principal seat of the linen manufacture is in Ulster; but, with the exception of Wexford and Wicklow, where it is unknown, it flourishes all over Ireland. In the neighbourhood of Belfast, at Leitrim, at Londonderry, in Donnegal and Tyrone, in Cavan, Louth, Meath, and Dublin, it flourishes in a remarkable degree. The quantity sold in Dublin, during the year ending March 1, 1809, appears from the following statement. (*Reports of Linen Board, VI.; App. 18.*)

Average value of 10,227 boxes inwards bound,	L.1,636,320
Ditto outwards bound, 9279 boxes,	1,738,590
Total,	L.3,374,910

The pieces of linen bleached in the county of Londonderry may amount to 250,000; and estimating the value of each piece at L.2, 5s. 8d., the actual value of the linen bleached in this county alone may be estimated at L.562,500. On the river Bann there are twenty bleachfields, which bleach annually, at an average, 8000 pieces, giving 160,000 pieces in all, the value of which is certainly above L.500,000. (Wakefield, I. 694.)

In the neighbourhood of Belfast and Leitrim, this manufacture has diffused happiness and prosperity; but in the remote districts of Mayo and Sligo, the effect upon the labouring poor has been just the reverse. So strongly does this appear, that Mr Wakefield gives it as his decided opinion, that the extension of the linen manufacture over the whole island, would bring with it an extension of poverty and famine, and would, if continued for any length of time, be the greatest curse which could be entailed on the country. (*Ibid.* I. 699.) It is remarkable, too, that this manufacture is solely the growth of artificial encouragement: for such is either the national aversion to industry in general, or to this branch of it in particular, that nothing is done without the assistance of government. A spinner, to be industrious, must be presented with a wheel; a weaver, before he will work, must be supplied with a loom; a bleacher to carry on his work, must be presented with a house in Dublin, for the purpose of selling his commodity. (*Ibid.* 698.) The following is a table of the sums expended in bounties by the trustees during the undermentioned years.

Years.	L.	Years.	L.
1802 .	13,857	1807 .	16,973
1803 .	8,861	1808 .	11,184
1804 .	13,064	1809 .	7,302
1805 .	11,423	1810 .	21,768
1806 .	13,243	1811 .	17,819

The Cotton manufacture was introduced into Ireland by Messrs Joly and M'Cabe in 1785, and seems, from the following table, to have taken a pretty strong root.

	Cotton Wool. Cwt.	Cotton Yarn. Lbs.
Average importation of cotton for three years, ending 1799,	10,983	460,013
Ditto 1807,	17,782	1,223,081
Ditto 1810,	32,257	1,057,115

This manufacture is principally carried on in the neighbourhood of Belfast, where, in the year 1809, it appeared, that in a circle of 10 miles it employed 27,000 persons. It has also spread to Dublin, Kil-

Ireland. dare, Wicklow, Wexford, and Louth. At Coulton in Louth, there are 1300 looms employed in calico weaving. Upon the whole, this branch of industry is spreading rapidly in Ireland, and promises, at no distant period, to become a staple article of manufacture. (Wakefield, I. 705.)

Woollen Cloths. The woollen manufacture does not exist to any considerable extent. It was formerly depressed and checked by the jealous commercial policy of England; and, though the Union has placed the two countries on an equal footing in this respect, the superior wealth and commercial enterprise of England have prevented all successful competition. Between 1794 and 1809, the total number of pieces exposed to sale, in the Woollen Hall of Rathdrum, did not exceed 55 000. The manufacture of woollen, however, in a coarse way, for their own consumption, is carried on to a great extent by the people. In many parts of the country the great mass of the labouring poor manufacture their own woollen cloths. In some places the women not only make stockings, petticoats, &c. for their children, but some coarse woollen articles for sale. (Wakefield, I. 710; *Survey of Clare*, 179; *of Kilkenny*, 522.)

Gloves and Linen. The manufacture of gloves, especially those called "Limerick gloves," is carried on to a considerable extent. Iron was formerly wrought to good profit and in great quantities; but all the foundries are now in disuse. Hardware articles, however, are manufactured at Dublin, and coarse implements of husbandry at Carlow. (*Ibid.* I. 721.)

Distilleries. The Distilleries of Ireland are very extensive, and the quantity of spirits made at the unlicensed stills, in all probability, still more considerable. In five years, from 1802 to 1806, 13,459 unlicensed stills were seized in Ireland, and 11,098 heads, and 9732 worms. The principal licensed distilleries are established at Limerick, Cork, Ross, Dublin, and Drogheda. In the year 1808, the greatest licensed distiller in the kingdom made 17,000 gallons a-week, and kept his distillery working between nine and ten months in the year. The following table exhibits the quantity of corn spirits for which duty has been paid in Ireland for ten years previous to January 5, 1813.

	Gallons
Year ending January 5, 1804,	4,426,085
Ditto, . . . 1805,	3,611,512
Ditto, . . . 1806,	3,756,671
Ditto, . . . 1807,	3,931,829
Ditto, . . . 1808,	5,707,158
Ditto, . . . 1809,	3,643,751
Ditto, . . . 1810,	72,006
Ditto, . . . 1811,	4,719,159
Ditto, . . . 1812,	6,500,561
Ditto, . . . 1813,	4,085,913

During the greater part of 1810 distillation was prohibited. From September 29, 1816, to February 5, 1817, there were 235,347 barrels of corn of 12 stone each used in distilling.

Breweries. It is but of late years that public breweries have been established in Ireland, but they have spread to a great extent. The principal breweries are at

Cork Fermanagh, Limerick, Waterford, Roscommon, Dublin, Belfast, Cavan, Armagh, Downmore, and Dungarrow; one of the largest brew in the island brews upwards of 100 000 barrels *per annum*. The following table shows the quantity of malt used in the breweries and distilleries from 1804 to 1817.

Year ending January 5, 1804,	995,649

Ditto, . . . 1816,	679,018
Ditto, . . . 1817,	479,633

The *Export of Manufactures* has increased very greatly within the last 10 years. The following table shows the progressive increase in the export of *linen*, the staple commodity of the kingdom, during the last, and that part of the present century which has elapsed.

	Years
Average from 1700 to 1750,	1,000,000
1750 to 1756,	11,790,361
1757 to 1763,	11,511,973
1764 to 1770,	17,770,862
1770 to 1777,	20,252,239

1. Year ending 25th March 1800,	55,676,008
3 to 5th Jan. 1801,	25,141,516
5 to 5th Jan. 1802,	57,767,077
1803,	35,491,131
1804,	36,432,365
1805,	12,988,621
1806,	12,531,971
1807,	39,019,727
1808,	40,901,442
1809,	45,001,382

And in the year 1819, there was exported to Great Britain alone 38,038,182 yards of plain, and 1837 of damask linen.

The following table shows the official value of the linen exported from Ireland in different years, from 1804 to 1820.

	Years
1809,	L2,933,109
1810,	2,478,869
1811,	2,460,280
1812,	2,095,657
1813,	2,389,722
1814,	3,141,806
1815,	3,132,451
1816,	2,317,411

Of this quantity, it is computed that upwards of L2,000,000 annually comes to Great Britain. Spain takes nearly L100,000 annually; the West Indies, in 1815, received upwards of L100,000, and the United States, in 1811, no less than L180,000.

Ireland.

Export of
Spirits

The export of *Spirits* was, on an average of seven years, ending

	Gallons.
25th March 1796,	10,284
Do. 10th Oct. 1802,	950,180
1803,	990,898
1804,	917,476
1805,	1,121,968
1806,	550,441

The great export of Irish spirits is to foreign states. The quantity exported to Great Britain, in 1819, was only 107,026 gallons.

Immense numbers of goose quills are annually sent from Ireland to this country. Those exported to Great Britain, in 1819, amounted to 9,541,320.

COMMERCE AND SHIPPING.

The following tables exhibit a general view of the

COMMERCE of Ireland from the year 1777 to the year 1815:

Official Value of Imports.

Average of Three Years, ending 25th March.	From Great Britain.	British Colonies.	All other Countries.	Total.

REVENUE, EXPENDITURE, DEBT.

Revenue of Ireland The REVENUE of Ireland is principally derived from customs, excise, stamps, and post office duties, and from assessed taxes on hearths, windows, houses, carriages, servants, and horses. The income-tax was never introduced into Ireland.

By the treaty of Union between Great Britain and Ireland, the latter was bound, besides paying the interest of the debt contracted before that period, and other separate charges, to make good 1/10ths of the public expenditure of the empire. This proportion was soon found to be much too great for her means. Notwithstanding a very great increase of taxation, the debt of Ireland increased so fast, that its interest generally amounted to about as much as, and frequently exceeded, the total revenue of the country. In this situation, and as the only means of avoiding a public bankruptcy, a proposition was submitted to Parliament for the consolidation of the English and Irish Exchequers. This measure was carried into effect in 1816. The debt of Ireland was incorporated with that of Great Britain; and, since the 5th of January 1817, the incumbrances, revenues, and expenses of the two countries have been blended together in one mass. The produce of taxation in Ireland is now considered merely as making a part of the general income of the empire, without any regard to the arbitrary proportion fixed in the treaty of Union.

The following is a View of the Revenue and Expenditure of Ireland in different Years.

	Permanent Revenue.		Expenditure.
	Gross Produce.	Net Payment.	
1791	L.1,805,961	L.1,184,684	1,800
1800	3,415,718	2,805,536	1805
1806	4,193,915	3,364,137	1810
1815	6,937,558	5,525,699	1815

The total gross Revenue for the Year ending 5th January 1817, the year previous to the Consolidation of the Exchequers, derived from the following branches, amounted to

Customs,	L.2,082,043
Excise,	3,208,931
Stamps,	611,709
Post-office,	222,747
	L.6,125,430

The total expense of collecting the various branches of the revenue of Ireland for the same year amounted to L.1,014,342. The following is a statement of the rate per cent. at which this expense was incurred, viz. for every L.100 paid into the Treasury under the heads of

Customs,	There was paid for expense of collecting	L. 35	11	3
Excise,		14	3	4
Stamps,		10	2	6

Army,	2,368,827	15
Miscellaneous services,	592,626	8
Vote of credit, arrear of 1815,	20,261	9
Total,	L.14,612,560	6 4 1

Ireland. The debt of Ireland, which, in 1800, amounted to about 25 millions, had increased in 1817 to about 152 millions, of which £141,441,180 was funded.

Oppressive-
ness of
Taxation. Perhaps no country has suffered so much as Ireland from the oppressiveness of taxation. Since 1808 taxes have been imposed in that country, which our finance ministers estimated would produce *three and a half* millions. In point of fact, however, they have not produced a single shilling. The nett revenue of Ireland in 1808 amounted to £4,417,990, while, in 1820, it only amounted to £3,605,446, being a decrease of £812,544. This fact affords a striking illustration of the folly of endeavouring to raise an additional revenue from an impoverished and exhausted country by a mere increase of taxation. Had Government made any vigorous effort to stimulate the dormant energies of the people, to give them a taste for the comforts and luxuries of civilized life, or to remove the most obvious of those causes of irritation and idleness which have so long distracted and depressed one of the finest countries in the world, the result would have been very different. But they contented themselves with adding to burdens which were already too heavy to be borne. The necessary consequences followed; consumption was diminished, the revenue declined, and all classes have been sunk deeper in the abyss of poverty and misery.

PUBLIC SCHOOLS AND CHARITIES.

Schools and
Charities. Notwithstanding the universal ignorance of the Irish poor, *the means of education*, within their reach, are by no means inconsiderable. It appears from the reports of the *Parliamentary Commissioners*, who have inquired into this interesting subject, that "there are 33 classical endowed schools in Ireland, besides 14 of private foundation, which educate nearly 1000 scholars: that, exclusive of parish schools in the city of Dublin, and in other places, supported by private endowments, amounting in number to 72, there are 44 public establishments for the education of the lower orders, in which 4200 children are lodged, maintained, clothed, and educated. The annual expence of these establishments is about £70,000." (*Report of Commissioners on Education*.)

The following returns, as to the number of schools actually taught, have been obtained from 17 out of the 22 dioceses into which Ireland is divided.

Dioceses.	Number of Schools kept by Masters who are Protestants.	Number of Schools kept by Masters who are Catholics.	Number of Scholars who are Protestants.	Number of Scholars who are Catholics.
Ardagh, . . .	21	104	1068	4310
Clogher, . . .	120	221	5702	5588
Cashel and Emly, . . .	31	191	746	10,815
Cork and Ross, . . .	78	103	2082	5101
Cloyne, . . .	36	143	952	9347
Dromore, . . .	105	44	3806	1710

Dioceses.	Number of Schools kept by Masters who are Protestants.	Number of Schools kept by Masters who are Catholics.	Number of Scholars who are Protestants.	Number of Scholars who are Catholics.
Clonfert & Kilmacdugh, . . .	7	61	273	2741
Down & Connor, . . .	986	90	10,260	3619
Derry, . . .	154	136	5835	3275
Elphin, . . .	23	110	1101	4651
Leighlin, . . .	16	144	1121	7691
Ferns, . . .	53	161	2406	9637
Killaloe & Kilfinora, . . .	43	176	1435	10,977
Kilmore, . . .	36	113	2031	4059
Meath, . . .	91	231	2195	12,225
Ossory, . . .	19	64	299	2841
Raphoe, . . .	73	72	2381	1878
Tuam, . . .	23	142	633	6972
Waterford & Lismore, . . .	29	159	1001	10,162
Total, . . .	1271	2465	45,590	116,977

From these returns, it appears that, exclusive of the charitable foundations, the number of children taught in these dioceses amounts to 200,000, that the schools of the two religions are 1600; and that there are, at an average, 43 scholars to a school. As these returns were made in winter, when many children cannot attend, and do not, besides, include the itinerant schoolmasters, it is probable, that the total number of children taught is more considerable. The instruction, except in a very few instances, goes no farther than reading, writing, and the common rules of arithmetic; and the fees paid, on an average, are 10s. *per annum* for reading, 17s. 4d. when writing, and £1, 6s. when arithmetic is added. (*14th Report of Commissioners on Education*.) These facts prove, that the means of education are afforded to the labouring poor; but they by no means show that the people gain any useful information, or are at all advanced in the scale of moral beings, by this instruction; nor do they supersede the necessity of a national establishment comprehending every parish in the island.

Ireland has no poor's rate; but in its principal cities a variety of most extensive charities are established. Many of them are maintained by the charity of individuals, and others by the munificence of government.

The following is a statement of the sums granted by the British government in the year 1818 to some of the principal charities and public establishments of the country

Protestant Charter Schools, . . .	£28,331
Foundling Hospital, . . .	32,515
House of Industry, . . .	36,643
Richmond Lunatic Asylum, . . .	7,085

Society for Educating the Poor, . . .	5,538

Ireland.

Ireland.

CHAP. II.

General Observations on the Condition of the People, and the Causes of their Depressed State.

All travellers who have inquired into the condition of Ireland, unite in representing the redundancy of the population as the main source of the sufferings of the people.* One cannot pass through a single county, without perceiving the most grievous effects resulting from this cause. In every town, in every village, there are multitudes of beggars, whose importunity testifies the need they have of assistance, while their famished and anxious aspect marks, in language not to be misunderstood, the anguish and suffering to which they have been subjected. The rich may exclaim against the impositions of the poor, and refuse charity to a hundred real objects of distress, because two or three have magnified their sufferings; but who will scrutinize the condition and appearance of the Irish poor will be convinced, that their numbers can hardly be exaggerated.

Nor is it merely in the incredible numbers, the incessant importunity, and deplorable aspect of the Irish beggars, that the superabundance of the population appears. It is an evil which is felt in every occupation, and in every corner of the land. In every line of life, in every branch of industry, there is an excessive competition for employment. If a small farm is to be let, the landlord is beset by numbers of persons wishing to take it; and who, in their anxiety to be themselves somewhere, offer the exorbitant rent of £25, £40, and even £50 per Irish acre for land, which, under their system of management, will hardly produce this sum. It is from this cause that the number of cottars is so inconceivably great, and that such high rents are given for the smallest pieces of potatoe land. In every other employment the same symptoms of a redundant population appear; and it is well known in the adjoining countries of England and Scotland, that wherever any public work is undertaken, there is almost instantly an inundation of Irish poor, seeking that employment which they cannot obtain at home.

Emigration, as might be expected, prevails, and has long prevailed, to a great extent in Ireland; but it has been unable to retard the progress of population. Between the years 1690 and 1745, it is computed that 150,000 Irishmen perished in the service of France alone. (Newenham's *Ireland*, 58.) Every nation almost of Europe has Irishmen in its service, and, independently of the vast swarms which continually come over to Britain, upwards of 1000 have annually, for a long period back, emigrated to America. (*Ibid.* 59.) During the year 1815, when the distress of the country was very great, the emigrants to America swelled to the enormous number of 20,000. (Newenham, 59; Wakefield, II. 712.) But this drain, great as it undoubtedly is, and materially as it must affect the population, from being composed entirely of persons in the

prime of life, is not perceived amidst the multitudes who remain. Every employment is still thronged to excess; and the departure of those who emigrate retards rather than accelerates the progress of wealth, for those who go have all acquired some little capital, and habits of industry, the subduction of which dries up the springs of national prosperity.

The actual population in 1805 has been estimated, by Mr Newenham at 5,400,000 souls. Mr Wakefield, after demonstrating, that, in 1791, it amounted to 4,200,000, observes that, since that period, a very great increase has taken place. (Wakefield, II. 712.) The rate of increase has been estimated by Mr Newenham and Mr Wakefield at an annual addition of one-forty-sixth to the whole population, in other words, the numbers of the people double in forty-six years. (Newenham, 220. Colquhoun, 21.) Thirty years ago, Mr Young expressed his astonishment at the prevalence of early marriages in this country. (Young, II. 198.) Mr Newenham and Mr Wakefield have reiterated the same observation in their late publications. Every road is lined with cottages, every cottage swarms with children. Under circumstances of unexampled distress during the last three years, the number of marriages and the multitude of children have suffered no diminution.

As might be expected in a country where the increase in the numbers of mankind has so far outstripped the progress of its wealth and the increase of its industry, the condition of the people is in every department marked by extreme indigence. (Dewar, 91; Young, II. 122.) The houses in which they dwell, the furniture in their interior, their clothing, food, and general way of life, all equally indicate the poverty of the country. In these respects, however, some improvement was observable, even at the time when Mr Young's *Tour* was written, and it has gone on increasing to a certain extent since that period. In the south of Ireland, the cottages have, in many instances, feather-beds, a luxury which they owe to the numbers of geese and poultry with which the country abounds,—a plenty which, in some degree, compensates to them for the many other privations to which they are subject. Considerable improvement in the condition of the peasantry was beginning to take place in the south towards the conclusion of the war, in consequence of the immense market and high prices which the consumption of the army and navy afforded; but these dawnings of prosperity have been almost totally overclouded by the distress of the last years.

It appears from evidence laid before a Committee of the House of Commons, that, in the year 1817, there were in Nicolson's Court, Dublin, 151 persons crowded into 28 small rooms; of these 89 were unemployed, and there were only *two bedsheads and two blankets in the whole Court*. In Barrack Street were 85 houses, the apartments in which were extremely crowded: 52 houses contained, in 390 rooms, 1318 persons, of whom 332 were adults

Ireland. out of employment, the greater part of whom were in extreme indigence. Church Street contained 181 houses, which were greatly more crowded than in Barrack Street.—In 71 houses of this street, and the adjoining courts, no less than 1997 persons were lodged in 393 apartments; of these 123 had been infected by fever within three months. There are many cellars in these houses which have no light but from the door, which, in several, is closed only by bundles of rags, vegetables, and other articles. In these cellars the people sleep on the floors, which are all earthen.

The dress of the people is so wretched, that, to a person who has not visited the country, it is almost inconceivable. Shoes or stockings are seldom to be seen on children, and often not on grown persons. (Young, II. 121.) The rags in which both men and women are clothed are so worn and complicated, that it is hardly possible to imagine to what article of dress they have originally belonged. It has been observed that the Irish poor never take off their clothes when they go to bed; but the fact is, that not only are they in general destitute of blankets, but, if they once took off their clothes, it would be difficult to get them on again. Their dress is worn day and night till it literally falls to pieces; and, even when it is first put on, it is usually cast-off clothing; for there is not one cottager out of ten who ever gets a coat made for himself. A considerable trade has long been carried on from the west of Scotland to Ireland, consisting of the *old clothes* of the former country, and to those who know how long all ranks in Scotland wear their dress, there is no more convincing proof of the poverty of the latter country can be given.

In England, markets and shops are established in every quarter, where the people may buy their necessities and conveniences. In Ireland there is neither the one nor the other. The Irish poor, indeed, have no conception of the comforts of life, and if they felt their full value, they could not afford them, for though necessities are cheap, conveniences of all sorts are very dear. Owing to the deficiency of manufacturing capital, the price of the commonest articles is fully as high as in Britain.

Ireland. while the money wages of labour are not equal to half the earnings of the English labourer; being in general from 8d. to 1s. 2d.; a sum altogether inadequate to obtain any portion of the comforts of life.* (Newenham, 272, 273.)

But while the Irish poor are in general destitute of all the accommodations, they hardly ever, except in years of extraordinary distress, know what it is to want the *absolute necessities* of life. The unsparing meal of potatoes, at which the beggar, the pig, the dog, the poultry, and the children, seem equally welcome, seldom fails the Irish labourer. In many cottages, the potatoe pot is constantly on the fire, and the children help themselves when they please (Young, II. 121); and to this cause, joined to the general use of milk, is to be ascribed the healthy appearance of the children in cottages which would seem to be the abode of the most abject misery.

The laziness of the lower Irish is very great (Wakefield, II. 776.) In many places it is so excessive, that two shillings a-day in England would be cheaper in the end than sixpence in Ireland (Young, II. 117.) This cannot be imputed to their potatoe diet, for there are numerous instances of persevering industry in Ireland. It is owing to the habits, the mode of payment, and the occupations of the labouring classes. Limited as their wants are to the mere support of animal life, they do not engage in labour with that persevering industry which artificial desires inspire; and the mode in which they are often paid, that is, the giving them a piece of potatoe land by the year, at once furnishes the means of subsistence, and takes away every stimulus to farther exertion. The farm-servants of the English or Scotch farmers, who carry on agriculture upon the improved system, are constantly employed in some species of labour; but after the potatoes of the Irish cottar are planted, there is hardly any thing to be done about his little croft till the season of digging arrives. During a great portion of the year he is doomed to idleness, and the habits he acquires during these long periods of almost total inaction, are too strong to be overcome when he is transferred to a more regular occupation.

* There is no person who has visited Ireland who must not be convinced that, *generally speaking*, these observations are strictly true. But, though the general aspect of the country is that of poverty and wretchedness, yet there are particular districts in which the progress of improvement has been so rapid and striking as to afford the most animating prospects; and even over the whole country, the increased consumption of articles of comfort, during the last twenty years, is very remarkable. "That Ireland," says Wakefield, "has made a wonderful progress in improvement, will not, I think, be denied by the gloomiest politician. In the neighbourhood of Belfast, this change has been peculiarly striking. This town, which, about a century ago, hardly deserved notice, is now, in trade and consequence, the fifth in the kingdom, hundreds, whose food consisted chiefly of potatoes, now use wheaten bread; thousands sleep in blankets and sheets who were formerly contented with a covering of straw. Having been frequently in Ireland during the last thirty years, my own observation has convinced me that a considerable change of habits has taken place, and that a taste for a more refined mode of life is beginning to diffuse itself among the people." (Wakefield, II. 65.) From the official return of the imports into Ireland from 1772 down to 1811, it appears that a prodigious increase in the consumption of articles of luxury has taken place in that period; far greater than the augmentation during the same time in the numbers of the people. (*Ibid.* II. 58.)

Ireland.

Such is the condition of the labouring classes. Ireland exhibits the extraordinary example of a country, in which, under the most distressing circumstances, population has advanced with the most rapid pace; in which cultivation has advanced without wealth, and education without diffusing knowledge; where the peasantry are more depressed, and yet can obtain subsistence with greater facility than in any other country of Europe. Their miserable condition will not appear surprising when the numerous oppressions to which they are subject are taken into consideration.

In the foremost rank of their many grievances, the general prevalence of Middlemen must be placed. It is difficult to estimate the extent of the misery which the system of letting and subletting land has brought upon the Irish cultivators. It has been observed, that the great cause of the prosperous situation of the peasant in Japan, is, that he pays his rent at once to the sovereign; that no person is substituted between the cultivator of the ground and the great landholder. (Thunberg's *Travels*.) With truth it may be said, that one great cause of the misery of the Irish peasant is to be found in the number of persons who are interposed between the landlord and the cultivator; for the whole fruits of their labour finds its way into the pockets of this middle class. (Wakefield, I. 287.) To absent landholders, middlemen are almost unavoidable; for without their intervention their estates could not be managed, and the collection of rents would be impossible. Middlemen have, in every country, been the inseparable attendants of *absent* proprietors; and in such a country as Ireland, where there are numbers of disaffected persons in every quarter, the vigilant eye of a superior inspector is more particularly required.

By the law of England, the landlord is entitled to distrain for payment of rent, not only the stocking which belongs to his immediate tenant, but the crop or stocking of a subtenant; on the principle, that whatever grows on the soil ought to be a security to the landlord for his rent; and in Scotland the same rule holds where the landlord has not authorised the subtaek; but if he has, the subtenant is free when he has paid to the principal tenant. There is little hardship in such a rule in England, where the practice of subletting is, generally speaking, rare; but when applied to Ireland, where middlemen are universal, it becomes the source of infinite injustice; for the cultivator being liable to have his crop and stocking distrained on account of the tenant from whom he holds, and there being often many tenants interposed between him and the landlord, he is thus perpetually liable to be distrained for arrears not his own. The tenant, in a word, can never be secure, though he has faithfully paid his rent to his immediate superior; because, he is still liable to have every thing which he has in the world swept off by an execution for arrears due by any of the many leaseholders who may be interposed between him and the landlord. It is obvious that such a system must prevent the growth of agricultural capital. This, joined to the exactions of the middle-

Ireland.

men, has been the true cause of the universal prevalence of the cottage system, and the minute subdivision of farms.

The mode in which the poorer classes are treated is strongly descriptive of their depressed situation. "The labouring poor," says Mr Young, "are treated with great harshness, and are in every respect so little considered, that their want of importance seems a perfect contrast to their situation in England, where, comparatively speaking, they reign as sovereigns. The landlord of an Irish estate, inhabited by Roman Catholics, is a despot, who yields obedience, in whatever concerns the poor, to no law but his own will. The language of the law may be that of liberty, but the situation of the poor may speak nothing but slavery. There is too much of this contradiction in Ireland. A long series of oppressions, aided by many very ill judged laws, have brought landlords into a habit of exerting a very lofty superiority, and their vassals into that of unlimited submission. Speaking a language which is despised, professing a religion which is abhorred, and being disarmed, the poor find themselves in many cases slaves, even in the bosom of written liberty." (Young, II. 127.)

In England, the Tithes can hardly be said, in a national point of view, to amount to a grievance. The precarious situation of the clergyman, possessing only a life interest in the benefice, joined to the wealth and consequence of the farmers and landholders by whom he is surrounded, precludes him, in the general case, from exerting his rights to their full extent, and softens the evils which the abstract powers with which he is invested might otherwise produce. But, in Ireland, the case is far otherwise. The relative situation of the farmer and of the clergyman are totally different, and a very different system in regard to the collection of tithes is pursued. The clergyman is, in general, far richer than any farmer in his parish; and he is connected with the Protestant interest, which has so long exercised an unlimited sway. Independently of the extreme poverty of the farmers, the livings in Ireland are, in general, much larger, and more lucrative than in England; so that the relative situation of the clergyman and his parishioners is totally different in the two countries. From the wealth and influence of the clergy, joined to the destitute situation of their parishioners, the tithes have long been collected with a severity, of which hardly any European state furnishes an example. They fall, by the law of that country, only on the tillage land, the greater part of which is held by cottar tenants; and thus the rich are exempted from bearing their share of the burden. (Wakefield, II. 486.) Almost everywhere the tithes are let to Tithe Proctors, who are acquainted with every man in the parish, who know the utmost length to which extortion can go, and exercise their powers with the most merciless severity. These proctors, besides what they pay to the clergyman or lay-impropriator, realize large incomes to themselves out of the produce of their extortions. When it is recollected, what savage ferocity has always been exercised towards these collectors in

Ireland. every commotion, it may be conceived how deeply their severity has been felt. (*Ibid.* II. 486, 487.)

What renders the tithing system peculiarly oppressive in Ireland is, that its exactions fall upon cottars who give the full value of the land in the rent paid to the landlord. The number of the labouring classes is so great, and the other branches of industry in comparison so inconsiderable, that the unfortunate poor are driven to take little spots as their only means of subsistence. The competition between them is so excessive, that they offer the highest possible rent for the land; as much, indeed, as the whole produce is worth, after their own food is deducted. The tithe is not considered by these unfortunate people; or if it is, they trust to the chapter of accidents for the means of paying it. But even if they had all the foresight of the Scotch peasant, they could not do otherwise; for having no other means of living, and being too poor to emigrate, they are compelled to run against each other for little farms; and of this competition the landlords too often avail themselves to screw the rent to the highest possible rate which the poor can afford to pay. (Wakefield, II. 493.) When the cup of misery is full, a drop will make it overflow. The tithes in Ireland are this drop. Inconsiderable as they are when compared with the burden which the tenants have to sustain in their rent, yet, when placed *in addition* to it, they operate as the last and most grievous oppression with which they are afflicted. To this cause we are to impute the remarkable fact, that while in Munster, where the tithe of potatoes is exacted, frequent risings have occurred during the last forty years; in Ulster, where no tithe is required, risings are unknown. (Wakefield, II. 493; *Life of Lord Charlemont*, 87, 88.)

What increases the hardship of this burden upon the people is, that it is not only imposed to support an establishment which they detest, which they consider as the badge of their national subjection, and which is so often negligent of its duty; but that it is an addition to a very expensive ecclesiastical establishment of their own, which they are obliged to support. The Irish Roman Catholic clergy, a numerous and not indigent body, are supported *entirely* by the contributions of the people; and the greater part of the income of the Presbyterians in the north is derived from a similar source. On occasion of a marriage, the priest receives from these poor people from two to three guineas; and the difficulty of raising this sum is perhaps the only check on the progress of population. (Newenham, p. 51.) From this and other sources the income of the Irish Catholic clergy is, except in years of extraordinary distress, very considerable; and this is a burden which falls solely on the poorer classes. Thus are the Irish peasantry, who, of all nations in the world, are the least able to support it, burdened with two separate ecclesiastical establishments, each of which levies its dues with the most rigid exactness; the one armed with the terrors of temporal authority, the other with the still more formidable weapons of superstition.

Another grievance, though not so extensive, is

Ireland. the fine imposed upon a township, for having had the misfortune to have a seizure for illicit distillation made within its bounds. Numerous are the families which have been utterly ruined, in every part of the country, by this most oppressive law. Many individuals are now languishing in prison who have been seized for the fine imposed on their township for an illicit still, of which they were utterly ignorant, or which they may have made the most vigorous though ineffectual, efforts to oppose.

From the facts collected by Mr Chichester (*Chichester on Still Fines*) on this interesting subject, it appears, that during seven years, from 1809 to summer 1816, the still fines levied amounted to L.356,925, or L.50,989 a-year; and the evidence of Sir John Stewart before the House of Commons shows, that, from 1809 to 1815, L.26,825 has been levied upon the county of Tyrone alone, and, on the county of Donegall, L.72,540. It appears, from the same authority, that the stills are of such a nature as to be generally incapable of discovery; that no provision is made for the case of absentees, who have, in more than one instance, been ruined by fines levied on their estates, while abroad on the service of their country; that the power thus vested in the hands of the revenue officers has been the occasion of infinite individual distress, as well as public discontent; and that the fines are levied, in general, by military force, and terminate in the utter ruin of the peasantry on whom they fall.

These evils have been attended with the usual depressing effects of oppression. They have prevented the growth of any artificial wants, or any desire of bettering their condition among the mass of the people. Despised by their superiors, and oppressed by all to whom they might naturally have looked for protection, the Irish have felt only the natural instincts of their being. Among the Presbyterians of the north, and in the vicinity of manufacturing towns, higher notions of comfort may have imposed some restraint on the principle of population; but the poor humiliated Catholics, enjoying no respectability or consideration in society, have sought only the means of subsistence; and finding, without difficulty, potatoes, milk, and a hovel, have overspread the land with a wretched race.

To these causes of a redundant population, of which the government of the country is, directly or indirectly, the source, are to be added others, of a different kind.

The first is the influence of the parish priests, who encourage marriage in order to increase their own emoluments, and the superstition of the people, who regard it as a religious duty. (Wakefield, II. 690.) In a country where the priests possess so much control over the lower ranks, and where the influence of artificial wants is so little felt, this circumstance must have a powerful effect. To this cause, joined to the degraded situation of the Catholic population, is to be ascribed the much greater frequency of marriages among the lower orders of that persuasion than among the Protestants. (*Ibid.* II. 578.)

The second cause is the general ignorance of the

Ireland. people. On the influence of education, in restraining the tendency to early and imprudent marriage, it would be superfluous in this place to enlarge. It is a mistake to imagine, however, that this almost universal ignorance, of which so much has been said, by almost every writer on the state of this country, is the result either of any inaptitude of the people to learn, or of any very remarkable deficiency in the means of education. The Irish evince everywhere the greatest anxiety for education, whenever the means are afforded. In the remote mountains of Kerry, schools are sometimes found in the wildest situations, where rocks supply the place of desks and benches. (Weld's *Killarney*, 187.)

Nor are the means of education either limited or scanty. In every quarter of the country, schools are established, and the cottagers can, in general, get their children instructed for five or six shillings a-year, in reading, writing, and arithmetic. (Wakefield, II. 399.) In the dioceses of Cloyne and Rossalme, there are 816 parochial schools, attended during the summer by 21,892 scholars. It may, indeed, be affirmed, generally, that, in point of literary attainments, the peasantry are greatly above the same class of men in England. (Newenham.) Yet it is strictly true, that the Irish are ignorant in the extreme. The solution of this seeming paradox is to be found in the poverty of the people, the absurd books which are put into their hands, and the want of religious instruction.

The poverty of the people is so great, that after they have learned to read, they are in general unable to purchase any book, or they are bred up in employments where reading is difficult by reason of the continued labour in which they are engaged. (Wakefield, II. 398-9.) In fact, it is impossible that knowledge can make any great progress in a country where the poverty of the people is so extreme, and where they are content with the mere support of life. In such circumstances, they necessarily want both the means and the inclination to turn their education to any good account. The books which are put into the hands of the children, so far from being such as are calculated to train them to habits either of order, virtue, or self-restraint, are precisely the reverse; being legends of saints, or histories of thieves, smugglers, and prostitutes, calculated to lead the youth of both sexes into every species of violence and depravity! It has, accordingly, been often observed, that the lower Irish, though educated, are utterly deficient in moral and religious knowledge (*Survey of Cork*, 714; Wakefield, II. 404); and to this circumstance much of the violence and cruelty which prevails among them is to be ascribed.

Various other circumstances have combined, to multiply to a great degree the facilities of population, and to expand, in this country, beyond almost any other, the means of subsistence.

Ireland. The first is the extraordinary fertility of the country, and the small expence at which cultivation can be conducted. Ireland contains 20,437,000 English acres, and of these above 13,000,000 are actually under tillage. The land does not require any expensive mode of culture; on the contrary, it is in general so rich, that it will yield an alternate crop of wheat and potatoes for ever; and can be taken into cultivation at a very small expence. But for this circumstance, the poverty of the Irish cottars, and the almost total want of agricultural capital, would have operated as a complete bar to a numerous population.

The second is the introduction of the Potatoe and its singular adaptation to the soil of Ireland. That this root furnishes food to the greater part of the Irish poor is universally known; but its effects in expanding the means of human subsistence are not sufficiently considered. The average produce of the kingdom is 82 barrels per acre, each barrel weighing 20 stone. This amounts to 22,960 pounds, which, divided by four to bring it to the solid nourishment of wheat, will be 5740 pounds. The average produce of an Irish acre of wheat is four quarters, which, at 460 pounds to the quarter, is 1840 pounds, not one-third of the solid nourishment yielded by the same extent of potatoes. (Young, II. 120.) Mr Newenham considers three pounds of potatoes as equal to one of wheat; at this rate, the acre will yield four times as much nourishment under the potatoe, as when cropped with wheat.

Potatoes have been introduced into every kingdom of Europe as well as Ireland, but in no other have they become the staple food of the poor. It is the condition and habits of the people, as they are determined by political institutions, and other causes, which fixes the standard of comfort and the age at which they marry. The introduction of the potatoe, by expanding the means of subsistence, removes to a greater distance the ultimate check which the inability of raising an increase of food must impose upon the multiplication of mankind; but taken by itself, it has no tendency to make the population advance faster than their comfort requires. It facilitates the multiplication of mankind, and increases the rapidity with which population advances; but, unless the people are predisposed, from other causes, to press upon the means of subsistence, it has no tendency to augment their redundancy. Under the government and political institutions of the Irish, the population of the country would have been equally redundant, though much smaller than it now is, if they had lived on oats or wheaten bread. The introduction of the potatoe may be the cause why the population is now six in place of three millions: but it is not the cause why, during the whole period of this increase, the numbers of the people have been greater than, under existing circumstances, could be comfortably maintained. (I. I. I.)

IRON-MAKING

Iron-
Making.
Discovery of
Iron.

The first knowledge of Iron, it is not improbable, was derived from the discovery of a meteoric mass of this metal. Such mass, existing in a state of considerable purity, and capable of being hammered into form, may have exposed the first rudiments of those valuable properties which have been applied with so much ingenuity and labour to the advancement of human affairs. Tradition says that the discovery of iron took place in Greece, in consequence of the accidental burning of a wood. This is certainly a possible case, where there might happen to exist on the surface masses of iron ore, a circumstance not very uncommon. Perhaps is a more probable conjecture to suppose that the discovery may have taken place, and been brought to a comparative state of perfection, in the process of converting wood into charcoal for domestic purposes. If the sylvan carboniser happened to pursue his art in a forest, occupying the surface of the mountain lime, abounding with ores of iron common to that formation, the casual introduction of masses of the ore in mixture with the covering matter of the fire would be unavoidable. In a fortunate moment, and under a happy conjuncture of circumstances, a lump might penetrate the ignited fuel,—a strong current of air might have arisen while the workman slept,—an unusual temperature might thus have been excited,—and (though injurious to the result of his labours) iron might in this way have obtained its first artificial existence. Supposing a partial knowledge of its properties to have been derived from the meteoric mass, this would lead to its immediate application to similar purposes. The success of the experiment would, of course, depend upon the quality of the product,—similarity of surface or polish, would, for a long time, most likely be the only properties in common to both,—uniform malleability, and extension under the hammer, could only result from a regularly constructed furnace, governed by long experience, and certain established rules of process.

Air-bloom-
ery.

Until the invention and use of bellows, the *Air-bloomery* seems the only mode by which iron could have been obtained. To say what was the first form or shape of this furnace is impossible. Such furnaces have long since ceased to exist in this country, and it is only by the remains of scoria, in elevated situations, that their former existence may be inferred. Park represents the air-bloomery of the Africans as a low, circular structure, containing, within very narrow limits, the aperture for admitting the air, and passing off the ignited gas. Air-bloomeries are still in use in Spain, and on the shores of the Mediterranean, where the ores of Elba are worked to considerable extent.

The rationale of the process is the deoxydation of the ore, by means of the contact of heat and charcoal.

Iron-
Making

To produce a beneficial result, it is necessary to use ores rich in iron, and united with as small a dose of oxygen as possible. The ores are stratified, and covered with charcoal, which is from time to time replaced as it becomes wasted by the progress of combustion. The ores during the lower degrees of heat, and period of deoxydation, are sheltered as much as possible from contact with the air. When the metallic particles are developed, an increased temperature is then necessary to unite the masses, and then exposure to air facilitates the process of welding. Lumps of the coalesced ore, impregnated with its earthly parts, and a portion of the iron in the state of *scoria*, are then taken from the furnace, and hammered into a rough bar called a *bloom*. This is subsequently reheated and drawn into plough-shares, or other implements which may be wanted.

As the facility of the air bloomery would depend in a great measure upon a steady and uniform current of air, seasons would occur, and even insulated periods of the same operation, wherein the process would either not proceed at all, or with languor. When the high temperature was necessary to complete by a union of masses, the result of the previous deoxydation, a strong off in the current of air would not only retard but destroy the economy of the process. Under such circumstances, during summer, or in hot climates, the invention of bellows would be hailed as a powerful auxiliary to the air-bloomery. Their application, at first, would most probably be confined to that part of the operation necessary to produce the welding temperature, but experience and observation would soon lead to higher and more important advantages, which, in the end, though they must have been the result of infinite labour and perseverance, amply compensated for the additional expense of a bellows blower.

The era of the *Blast-bloomery* must indeed have been the commencement of an important revolution in the art of iron-making. This will be better understood by contrasting the principles in the two operations respectively. In the *Air-bloomery*, the ore was, by means of the charcoal in contact deprived of its oxygen, and, as an inevitable consequence, aided by the increased temperature passed into the state of soft or ductile iron. In the *Blast-bloomery*, not only was the ore deprived of its oxygen, but, by the higher and more uniform temperature occasioned by the use of bellows, a union took place between the iron of the ore and the charcoal of the fuel. This combination would immediately produce fusibility; and crude or cast-iron, or an imperfect steel, would first make its appearance in the early stages of the blast-bloomery. The soft and ductile preparation of iron, which resulted from the air-bloomery, would no longer appear, but become

Iron-
Making.

mixed with a new and crude species of the metal, incapable of being hammered, and communicating to the more perfect product a deleterious quality;—the bellows would, in many instances, be laid aside, and their usefulness in the process denied, or at least doubted. Chance would discover to some smith, more intelligent than others, that, by frequent attempts in forging, the new metal was improved; he would soon observe, or discover, that this additional process might be considerably abridged, by directing the nose of the bellows upon the metallic regulus, before it was, in the first instance, removed from the furnace. Thus a new form of furnace would be suggested, having for its object the complete fusion of the ores, and the separation of the iron from them in a fluid state. Hence eventually resulted the blast-bloomery, in its most perfect and expeditious form, making in one day as much iron as an air-bloomery could in a week, and in a manner more economical, whether the measured result in metal from the ores or the abridgment of labour are considered.

The blast-bloomery of this country is still recollected by some very old men. Its form was either circular or square, its height from three to four feet. Previous to blowing, it was nearly filled with charcoal, then a charge of ore, over which was thrown a larger charge of charcoal. The blast was urged by means of bellows, suitably constructed. The ores were thus rapidly heated, and deoxygenated in the upper part of the furnace, as the ore descended and approached the blast, a portion of the fuel, by the increased temperature united with the ore,—fusion ensued, and nearly all the metallic contents were precipitated on the bottom of the furnace. The nose of the bellows was directed and corrected upon the surface of the mass,—combustion and copious scoria ensued, which was removed from the furnace by repeated tapping. This operation was continued, and hastened by frequent stirring, till the remaining iron had, by an effectual decarbonization, passed into the state of soft or malleable iron. It was then broken into convenient masses, carried to the hammer, and formed, as in the bloomery, into blooms. In a more advanced and enlightened period the defects of the air-bloomery are many and striking. The cementation necessary to deoxygenate the ore, previous to fusion, must have been, from the smallness of the furnace, partial and imperfect, and acquired at an immense sacrifice of fuel. The process was not, as in the modern blast-furnace, continuous; each charge, composed of a certain measure of charcoal and ore, was smelted, separated, and worked, before the furnace was filled for a renewed operation. When the charge of fuel happened to be in excess, which would sometimes be the case, the iron would imbibe an extra quantity of carbon, and be proportionally fusible; this would demand a prolonged action of the blast on the surface of the metal, and thus consume time in an unprofitable waste of the metal. The imperfection of the process may be pretty correctly estimated from the variety of slags, and the quantity of iron they contain. The Roman and Danish castles now found, and which were the current production

Iron-
Making.

of the blast-bloomery in remote ages, contain from 25 to 30 per cent. of iron, and have, in the last three hundred years, been extensively in use as ores, for the production of iron, in the blast-furnace.

To the blast-bloomery, in the art of iron-making, Blast-substituted a larger furnace, which is now known by furnace. the name of the *Blast-furnace*; and from the discovery of which, the *Poussière* and *Forge*, including the *Finery*, must have resulted. The vast advantages of this furnace arise from the continued action of reduction, a complete separation and recovery of all, or nearly all, the iron originally in the ore,—a greatly increased quantity in a given time—and a lessened consumption of fuel in the manufacture. Unlike the imperfect reguli of the bloomery, the metal of the new furnace was fluid, could be collected and remain so for many hours in the bottom of the furnace, and then be run into channels formed in sand,—but in this state, from the extra dose of carbon, it did not possess any property fitting it for the hammer, or for rendering it capable of being formed into a bloom, without subsequent operation. The effect produced in the blast-bloomery, by directing the bellows upon the surface of the separated iron, most likely suggested the idea of a separate furnace, in which a similar operation might be performed, without any connection with the previous smelting. The latent but unerring operations of chemical causes, accidentally associated with a larger furnace, and the favourable proportions of ore to fuel, would produce a fluid metal, which, along with the scoria flow unexpectedly from the furnace, might thus first exhibit iron under a new form of existence. This would directly lead to experiments in the bloomery, with a view to obtain uniform and consistent results. In time it would be found out, that, owing to the height and capacity of the furnace increased, the fusibility of the iron, and produced it of sufficient fluidity to run from the furnace. This fact once ascertained, would open a new field of observation and experiment, and the dimensions of the furnace would only be limited by the sparing quantity of air, or blast, afforded by the imperfect bellows of the day. For a time this would be partially remedied by the use of a suspending medium in the furnace, since called *boies*, but, in the end, the advantages of the large furnace would lead to an improved construction of bellows. The foot and hand blast bellows would give way to others moved by greater animal power, and these in their turn yield to larger bellows moved by the water-wheel. The power of a dozen bloomeries would be now concentrated in the new furnace,—convenience and locality to ore and fuel would be sacrificed to moving power, only to be obtained by the concurrence of water and fall.

In tracing the art through the lapse of ages (during which no memorial of facts has been preserved relative to the progress of iron-making), it seems evident, that its first general establishment, under the system of bloomeries, must have been on elevated situations, for the purpose of obtaining a powerful current of air. After the invention of bellows and the blast-bloomery, the art must have been carried into the plain,—every village and township where ore had

Iron-
Making

wood abounded would have its furnaces and smiths. The completion of the blast-furnace would once more remove the site of the manufacture, and the powerful blast of the new bellows, and the sturdy blows of the forge hammer, would, in the valley, supersede the more languid operations on the plain.

It is difficult to ascertain the period of the introduction of the blast-furnace into this country. Even in Dean Forest, the most ancient iron-making district, there exist no facts to show when it was there introduced, nor does tradition in any way assist us in the difficulty. In a publication of Dudley's in the reign of James I., the blast-furnace and other improved branches of the iron trade are there spoken of as *having* been extensive, "but now falling into decay, owing to the scarcity of wood." The art of the founder seems, too, at this period, to have been extensively practised, and judging from specimens still in preservation, considerable taste and skill in carving and relief must have been practised by the model makers of that period; and we know the fact of England's exporting, in the early part of Elizabeth's reign, a considerable quantity of such heavy ordnance as was then in demand. The civil commotions, excited by the long and disastrous contentions of the houses of York and Lancaster, were most unfavourable to the introduction or improvement of the arts or manufactures. It is more than probable, the use of the blast-furnace was first known in the time of Henry VII. Whether it was a native or an imported discovery does not now appear. On examination, the sites of the first class of blast-furnaces are found to have been placed on small streams near their source. The supply of water for moving the bellows was, of course, confined to the winter months, and, according to the copiousness or permanency of the stream, the furnace would be kept blowing four, six, or eight months. In an age when the division of labour was little understood and less practised, the disadvantages of this partial supply was not so great as they at first sight appear. The summer months were employed in procuring a supply of charcoal and ore for the winter consumption, and the same class of labourers passed from the furnace to the mines, or to the woods, and practised with equal facility their various callings.

From the period above alluded to, up to the present time, the only improvement to be traced in the charcoal blast-furnace is the increased size, and corresponding increased power of the blowing-machine. By the removal of the establishment from a solitary stream to a greater depth in the valley, where a larger portion of the drainage of the district had united, giving greater power and permanency of supply to the water-wheel, the weekly produce in iron has been increased from 10 to 25 and 30 tons; and a furnace, ~~and~~ using the improved system, has been kept in blast for ~~some~~ years together. In the plates which accompany this article will be found drawings of furnaces used in the time of James and Charles I., and in our own time. The former are proportioned from the hearth of one of the King's furnaces, lately discovered in Dean Forest, and which

furnace has not been at work since the commencement of the Civil Wars.

Iron-
Making

Although in tracing the progress of iron-making from the bloomery to the blast-furnace, it is seen, that, in all cases, the great object to be obtained was soft or malleable iron, yet we see the career of improvement, as if resting in the completion of a furnace, for the purpose of making an entirely new species of iron, possessing (except in weight) no properties in common with the tough iron of the bloomeries. But in this, as in every department of manufactures and the arts, the division of labour and of process have proved the true road to excellence. The division of iron-making, by whomsoever invented, into two distinct processes, must, at the time, have been marked by great and permanent effects. The manufacture of crude iron in the blast-furnace, and its subsequent malleabilization in the refinery, being operations not at all connected with each other, could be let alone, or carried forward, as best suited the views of the iron-maker. One man might smelt, and another purchase his iron and refine it. In place of obtaining from the bloomery one-fourth and one-third of malleable iron from the ore, the blast-furnace revived and returned, in a manner strikingly perfect, the whole iron of the ore, though in a state of crudeness or brittleness: though this was afterwards subjected to a loss of 25 per cent. in passing through the refinery, still, on the whole, it may be properly estimated, that, by the invention of the blast-furnace and the refinery, nearly double the quantity of iron, from the same weight of ores, was brought to market. The difference between the scoria of the bloomery and the blast-furnace would be so striking and manifest, that comparison would be succeeded by experiment. When the former were found to yield an abundant supply of iron by being smelted in the blast-furnace, a new species of property was created in the country. The spoil of the iron manufactures, from the time of the Romans downward, became at once, and for centuries, mines for the principal supply of the blast-furnace. Extensive proprietorships of Roman cinders (as they were called) were formed. Forests, covered with decayed oaks, were uprooted, and plains that had slept for ages under a great depth of soil, were unbarred to pour forth their newly created treasures. In Dean Forest, it is computed, that nearly twenty furnaces, for a period of upwards of 300 years, were supplied chiefly with the bloomery cinders as a substitute for iron ore. These were used in the proportion of five-eighths of the whole charge, the remainder being made up of the calcareous ores from the mines of the mountain lime, and a portion of lean argillaceous and siliceous iron-stones, accompanying the coal measures.

Dudley says, that in his time there were in England 300 furnaces for the manufacture of pig-iron; that each had forty weeks supply of fuel, and made, while at work, fifteen tons weekly, making in all the incredible total of 180,000 tons annually; and this, too, at a time when he represents the trade as in a decaying state, from the failure of the supply of wood. Either his statement must have been un-

Iron-
Making.

thinkingly exaggerated, or a great falling off in the manufacture must have taken place in the next hundred years; for we have it on good authority, that some time before pit-coal became the fuel of the blast-furnace, about the year 1740, the following quantities were respectively made in the English and Welsh iron-making counties:

	Furnaces.	Tons.
Brecon,	2	600
Glamorgan,	2	400
Carmarthen,	1	100
Cheshire,	3	1,700
Denbigh,	2	550
Derby,	4	800

state of this
Manufacture

Hitherto we have only spoken of the manufacture of iron in this country, as connected with the charcoal of wood as the basis of its operations. The gradually increasing population of the country had converted to other purposes a great portion of these woodlands that had formerly supplied fuel for the furnaces, and a period had arrived, when either a substitute must be found, or the manufacture of iron cease to be one of the staples of the kingdom. From Dudley, we learn, that James I. had granted many patents in divers parts of the kingdom for the manufacture of iron with pit-coal; that the attempts had uniformly failed, except in his own case, in 1619, when he succeeded to the extent of three tons weekly. The same gentleman, applying in 1663 to Charles II. for another patent for the same object, states, that he had succeeded at one time in making to the extent of seven tons of coke pig-iron weekly. But it was not till about the year 1750 that pit-coal became a general and profitable substitute for charcoal of wood in the blast-furnace. Subsequent experience shows the cause of this tardy advancement to have arisen from the want of a sufficiently powerful blowing apparatus. The introduction of the steam-engine, and the consequent increase of iron now made, soon pointed out the deficiency under which all former experiments had been made with pit-coal. The incombustibility of coke, compared with charcoal, requires a more copious and powerful discharge

of air, in order that it may perform profitably the functions of smelting and carbonating the metal. As soon as this was made evident, it not only stimulated the manufacturer to erect appropriate blowing apparatus for his coke pig furnace, but it led to an immediate improvement in the blowing machinery of the charcoal furnaces, still supplied with wood, so that, in 1778, about forty years after the collation of the foregoing table, we find the state of the charcoal pig-iron manufacture to be as follows:

Iron-
Making.

	Furnaces.	Tons.	Total.
Glostershire,	4	650	2,600
Monmouthshire,	3	700	2,100
Glamorganshire,	3	600	1,800

	Tons. cwt. qrs.
Average weekly quantity produced in 1788,	10 9 3
Do. in former period, 1740,	5 13 0
Weekly increase in favour of the improvement,	4 16 3

But, during the same period, it is evident, that an annual diminution of the manufacture of charcoal pig-iron was experienced to the extent of 4250 tons, attributable to the decrease of wood, and consequently the use of coke pig-iron as a substitute. This deficiency was, however, amply compensated by the rapid increase of the manufacture of coke pig, as proved by the following statements:

Coke Pig Furnaces in England and Wales, in 1788.

	Furnaces.	Tons each.	Total.

	in 1740,	17,350	
Annual increase of pig-iron,			50,950

About the year 1796, Mr Pitt had it in contemplation to add to the revenue, by a tax upon coal at the pit. This, of course, led to a powerful opposition on the part of the manufacturing consumers, particularly in the iron trade. A committee was appointed, witnesses examined, facts collected, and the measure abandoned, as being unwise and impracticable. The following table, while it exhibits an abstract of the facts collected, shows the rapid progress of the iron trade in the course of the eight previous years:

Counties.	Number of Furnaces.	Excise Return of Iron made.	Supposed quantity by the Trade.	Actual Return.
		Tons.	Tons.	Tons.
Chester,	2	4,710	2,200	1,958½
Cumberland,	4	5,144	3,000	2,034
Derby,	3	2,138	2,138	2,107

	104	167,321½	133,950	108,793

The return from Scotland exhibited a list of 17 furnaces, and an exact return of pig-iron manufactured, 16,086 tons.
Making a whole annual quantity of 124,879

Annual average produce from each furnace, which also includes the charcoal furnaces, 1032
Annual average of 1788, including the charcoal furnaces, 800
Increase tons, 232

In the six following years, there were built and

building in England and Wales 40 additional furnaces, and in Scotland 7, the collective manufacture of which was computed at upwards of 170,000 tons annually. Nor did the trade, at this period, become stationary. Its unexampled increase and prosperity attracted the cupidity of the minister of the day; and it was reserved for a popular administration to fail in a financial speculation, which, if carried, was to cripple one of the main-springs of national prosperity. In 1806, a bill was brought into Parliament, having for its object a tax of £2 a ton on all pig-iron made, and of placing the manufacture itself under the supervision of the excise. The bill itself was an anomaly in legislation, and though armed with powers and clauses in abundance, could not possibly have been acted upon. It was framed in utter ignorance of the nature or details of the manufacture, and contributed much by its absurdity to the failure of the cause it was intended to support. The union necessary to oppose the bill with effect produced a new series of facts, regarding the extent and progress of the iron trade in the kingdom, showing at that time its annual amount of product to be at least 250,000 tons. Since that period, the manufacture has gone on increasing; and, though subject to great depression in 1815 and 1816, has, during the last three years, resumed its former activity. The manufacture of pig-iron, in Wales only, may be computed at, tons per annum, 150,000
Shropshire and Staffordshire, 180,000
Yorkshire and Derbyshire, 50,000
Scotland and other places, 20,000

Total, 400,000

Having thus narrated the progress and increase of the manufacture of pig-iron, we shall next describe, as concisely as possible, the economy and order of the process itself, both in the charcoal and coke blast-furnace, as at this time practised. Plate LXXXIX. fig. 1. represents a charcoal-furnace of the largest dimensions; blown by three iron cylinders, moved by a water wheel, and so constructed as to be blown at either side, or at the back through openings called twyers. The furnace is filled with charcoal, which is gradually ignited to the top, when a charge of ore is put in, with a proportion of flux, along with a certain number of baskets of charcoal. The furnace is from time to time opened below, and large bars of iron are introduced to serve as a temporary grate, through which the air may pass to the whole body of materials in the furnace. By the time the ore reaches the bottom, a considerable temperature has been excited, indicated by occasional fusions and scintillations. These are the general signals for introducing the blast. The furnace is shut up in front by means of a stone called the dam-stone, and space is left between this and the front-stone or tym, which is filled with sand. The twyer is then opened and the blast introduced. Entire fusion commences. In a few hours the earthy matter of the ores accumulate in the state of glass, and are allowed to flow out at the opening in front, between the dam and tym stone. In the meantime the iron, by its superior weight, falls to the bottom,

Iron-
Making.

Iron-
Making.

where it is allowed to collect for twelve or eighteen hours. The furnace is then *tapped* in an opening left on one side of the dam-stone, and the metal flows along a channel made in sand, called the *son*, into the moulds prepared for it in the *pig-bed*. The charge introduced from time to time as the smelting and reduction take place, is called the *burden*, and this burden varies considerably, and at different works materially, owing to the quality and richness of the ore. For many years past charcoal iron has been made chiefly with the red hematitic ore of Lancashire, the uniform quality and richness of this "*mine*" rendering the operation of smelting a matter of greater certainty. Four large baskets, containing about ten bushels of charcoal, will smelt and carbonate the iron contained in four hundred weight of ore. With the necessary proportion of an argillaceous ironstone flux, this quantity will yield $2\frac{1}{2}$ hundred weight of iron. In the neighbourhood of Dean Forest, the calcareous ores of that district have been superseded by the use of Lancashire ore, except as a flux, for which purpose a lean carbonate of iron, much mixed with a sparry carbonate of lime, containing about 20 per cent. of iron, is used in the proportion of one-sixth to one-eighth of the ore. A charcoal furnace will consume from twenty-five to thirty thousand sacks in a year, each containing eleven to twelve bushels charcoal, the produce of at least one hundred and twenty acres of woodland. If the wood replaces itself fully in twenty years, then twenty-four hundred acres of land would be necessary to keep such a furnace at work.—Coke to manufacture the same quantity of iron is obtained from less than half an acre of the Staffordshire main coal.

The preparation of the coke blast furnace is similar to that practised with the charcoal blast-furnace, but its workings and burdens are infinitely more varied and complex than that of the latter, which, from the uniform quality of wood charcoal and Lancashire ore, experience has reduced to a certainty in every possible change and proportion arising from burden. In the coke furnace the case is widely different;—every new situation has, in the nature of the coal, and the quality of the ore, something novel and characteristic. The argillaceous ironstones generally used, are not very various in point of richness; few when roasted are under 35 per cent., and equally few exceed 45 per cent., and their composition generally unite siliceous, lime, and clay. As it is the convenient practice at most works to mix lean and rich ores together, so as to reach a common standard of 40 per cent., there can be no material difference occasioned by the quantity of the iron used in the ore, the average produce of which may be correctly taken all over the kingdom at $37\frac{1}{2}$ per cent. It was long considered a fair burden if the coke carried, that is to say, smelted, and carbonated the iron contained in an equal weight of the ore.—This is now materially exceeded in Wales and in Staffordshire. At Blanacon, in the former, the coke smelts double its weight of ores, and in that principality generally, it smelts 50 per cent. more ore than its own weight. The same thing takes place in Staffordshire and in Shropshire; but at some furnaces

Iron-
Making.

in Derbyshire and in Yorkshire, the coke does not smelt above two-thirds its weight of ore. Again, some coals in coking yield 65 to 70 per cent., while others yield not more than 35. Hence a ton of iron is made at some furnaces under three tons of coal, and at others eight or nine tons are required for the same purpose. This great variety in the fuel renders general rules of little or no avail; a few simple principles, however, arising out of observation and experience, are understood and practised at all iron works.

The ironstones of this country, were they fused under the most favourable circumstances as to coke and blast, would not, without a mixture of lime or limestone, afford a perfect result,—the glass or *scoria*, from the excess of siliceous, would be languid and tough, the iron would separate imperfectly, and its quality be injured by combination with silicium, in the absence of lime. The latter having a greater affinity for siliceous than for iron, readily unites with the former, and leaves the iron to the full action of the carbon, and, like all mixtures, forms a more fusible compound than either separately. This mixture of the earthy matter of the ores is called cinder, scoria, or slag. In flowing it indicates, by its degree of heat, colour, and fluidity, with the most accurate precision, the quality of the iron accumulating in the furnace. Lime, however essential to a proper flow of cinder from the furnace, is not primarily the cause of change in the quality of the iron,—coke is the powerful vital agent,—on its properly proportioned quantity and its quality the whole result depends. In vain will it be to harmonise in quality and proportion the other materials, if the proper quantity of cokes be not present to reduce the charge into a proper state of division, and to carbonate the iron to such an extent as to pass the blast without oxidation. When the due proportion of lime and coke are present in the charge, the cinder flows from the furnace, sometimes transparent, opaque, white, glassy, variously mixed with fine tints of blue, and nearly free from oxide of iron. The metal accompanying such a cinder is what is called carbonated, or grey pig-iron. If a portion of the coke is withdrawn from the charge which gave out such results, the cinder instantly changes to a brownish black, or entirely black colour,—the iron parts with its carbon, becomes white in the fracture, deteriorated in the quality, and the whole operations of the furnace become disordered.

Having thus traced the general progress of the iron Manufacture in Britain, commencing in a period of conjecture, and from beginnings the most limited and rude, to a state of most unexampled prosperity and national grandeur, during which the object of the iron-maker had changed from the production of malleable iron, in the first process, to that of crude iron, it is now necessary to retrace our steps, and pursue the subject as connected with the manufacture of malleable iron, or, as it is now called, bar iron. The advantages produced by the inflection of the bellows pipe in the blast-bloomery, as has already been noticed, most likely furnished the first idea of the refinery furnace, or the discovery might have been purely

Iron-Making.

accidental. A piece of cast iron, by some unforeseen, but possible circumstance, formed in and tapped from the bloomery, would, by its novelty, arouse curiosity and conjecture; and although, by simple heating, it would not yield to the impression of the hammer, yet, by a second fusion in a common smithy fire, new properties would be developed, and in the end, ductile iron would be obtained. It is likely that, for a long time, these occasional runnings from the bloomery would be considered as a species of waste, and from time to time worked up by the common smith, while the bloomery performed its more extensive functions. As the smith became more perfect in his art and manipulations, iron produced in this way would be possessed of superior strength and ductility, and would eventually obtain a preference in price and demand in the market. Thus a powerful inducement would be held out to the Bloomery proprietor, to increase, by direct experiment, the quantity of cast iron, and to devise a method by which it could be regularly made; nor would the manufacturer stop short till a furnace was constructed, continuous in its operations, and regular in its results, as to the production of cast or pig-iron. From that moment the refinery became a furnace of the utmost importance to the iron trade. The process here performed was bold and philosophical—nothing short of subjecting the most refractory of all metals to a violent combustion could free it from an admixture which, but for this, must have remained a perpetual bar to its ductility. The open cavity of the furnace being filled with charcoal, a fire, by means of the bellows pipe, more or less inclined, was soon created; the cast iron of the furnace was placed upon the burning fuel; in time it melted, and, dropping in detail, passed before the current of air issuing from the bellows, and, deprived of its carbon, sunk under the level of the nose-pipe, having lost its fluidity, and become sufficiently coalesced. Iron bars were then introduced; the clotted iron, broken into pieces, and brought a second or a third time up above the level of the blast, till a sufficient refinement had taken place to enable it to stand the blows of the forge hammer. In this operation of refinement, or burning out the carbon, the iron entered into a complete state of combustion, and a considerable portion of it was converted into scoria. The creation, management, and quantity of this scoria were matters essential to be understood, and properly practised, both as to the quality of the iron and the economy of the process.

The quantity of iron wasted in this operation depended upon the quality of the cast iron made use of. If the iron was highly carbonated, an extra tendency to fusibility existed; and a greater duration of exposure to the blast was necessary, to render the iron tough and ductile. From 25 to 35 per cent. of the whole iron introduced was, by this process, converted into a glass of iron, containing from 45 to 50 per cent. The operation itself, compared with after events, was simple and expeditious, and the quality of the iron good. It is by a similar process that the superior qualities of iron brought from Russia and Sweden are at this day manufactured; and the same mode is in general practice all over

Iron-Making.

the Continent of Europe. In this country, the use of the finery continued as the only means by which iron could be profitably rendered malleable, until some time after the introduction of pit coal in its manufacture. When coke was first made use of in the blast-furnace, charcoal was still used in the common refinery, for the decarbonization of the iron to be made into bar iron; but it was found necessary to add another process to overcome the deterioration in the quality of the coke pig-iron. The lumps formed in the refinery were afterwards heated, and drawn out into blooms, and these again into bars, according to the quality of the iron wanted. As charcoal became scarce, the manufacturer ventured to add, in the refinery, a small portion of coke along with the charcoal, endeavouring, in the after part of the manipulations, to overcome the consequent deterioration of quality; but, as charcoal was at last entirely abandoned, and coke exclusively used, a considerable variation took place in the process. In place of forming the product of the refinery into lumps, which exposed very little surface when afterwards re-heated, the masses from the refinery were carried and put under a heavy hammer, of four or five tons weight, and beat out into a ragged sort of plate, called *stamp iron*; these were again broke, by mechanical force, into small pieces, and their qualities examined. Those pieces, little removed from the nature of pig-iron were called *ram*, and thrown aside to be refined. The perfect plates were built into piles of 50 lbs. to 70 lbs. weight; and each pile was placed upon a tile stone, or fire clay plate, or incased in a large rough sort of crucible, called a balling furnace pot. When a sufficient number of these were in readiness, a batch was introduced into a large furnace, heated with flame of pit-coal. When the temperature had been sufficiently raised to weld the parts together, each ball or pile was removed from the furnace in succession, by a pair of tongs, carried to the hammer, and formed into a bloom, being a short thick bar of iron. These blooms were re-heated in a fire, called the chaffery, and put under a lighter and more active hammer, where they were drawn into their destined shape.

A considerable waste of iron was in these various processes sustained, amounting to ten or twelve hundred weight for every ton of bars that were finished; but the difference of the price of fuel compensated for this additional loss; and the necessity of the case, from the diminution of wood, and increased demand, had become imperious. The manufacture of bar iron remained subject to the stamping process many years, and the quality of the iron so made was strong, and generally tough; but the tardy finish of the hammer, and the arrangement of the whole, was not calculated speedily to overcome quantity; and it was considered a respectable establishment that could turn out, in one week, twenty tons of bars fit for the market. Refineries could not be multiplied without an additional increase of blast; and this, in general, could not be done without additional steam-engines; and, in short, the manufacture had become apparently stationary, when the genius of Mr Cort furnished the ardent minds of his countrymen with a new and interesting field for enterprise. When Mr

Iron-
Making.

Cort laid before the public his new plans, so inadequate was this country to the supply of its own demands, that it imported from Russia and Sweden the enormous quantity of 70,000 tons of bar-iron annually. The object of Mr Cort's processes was to convert into malleable iron, cast or pig-iron, by means of the flame of pit-coal in a common air furnace; and to form the result into bars by the use of rollers in place of hammers. He made many experiments, and expended large sums of money, in the progress of establishing his inventions; but, so long as the various qualities of pig-iron only were the subject of operation, the results in the puddling furnace (his invention) were uncertain, attended with waste, and unequal in quality. These obstacles were at last removed by the operations of the coke-refinery, already alluded to. In refining grey or fusible iron, it was in common practice to tap the fusion, immediately upon its being smelted, into a flat-box. This plate of iron being so far refined, was again thrown up on the fire, and passed a second time before the blast. If still too fine to come into "nature" it was again put on the fire, to complete its decarbonization. Some of these plates being taken to the puddling furnace, were observed, in working, to possess properties, both as to facility and quality, very superior to the best pig-iron. It then occurred that the finery ought to be employed, not as formerly, to refine the iron to the extent of malleabilization, but merely to decarbonize it to a certain extent, and to fit it more properly for the operation of puddling. This gave rise to the very extensive practice of "running out," which gives complete certainty to the puddling process. In this new refinery, or "running out fire," the various qualities of pig-iron are, by the skill of the workman, mixed and reduced to a common standard, which is now called finer's metal. By this means, the operations of the puddler are rendered certain, and he can reckon, within a few minutes, the continuation of his operation. In the commencement of this, as in all new things, much difficulty and waste of iron was sustained, and only a limited quantity overcome. The loss now, when the refinement is carried on in one fire to the extent of sixty to eighty tons a-week, is estimated not to exceed 2½ cwt. per ton, or 12½ per cent.

The puddling furnace, from which the refined metal is thus prepared, is, in its general form and appearance, not unlike a founder's air furnace. It is heated by means of pit-coal, on a grate; and, as may be seen in the drawing, has a chimney of considerable height, in which there is a damper, to regulate the degree of heat while puddling. A considerable portion of the space between the grates and the chimney is formed flat, and covered with a peculiar sand, possessing the properties, when heated, of becoming very hard and infusible. On this space is placed 3 or 3½ cwt. of finer's metal, and the flame allowed to pass over it with the full force of the furnace. In twenty minutes, the iron assumes a yellowish white colour, and marks of fusion appear on the angles of the pieces; the puddler then turns up new surfaces to the flame, and keeps breaking those which have reached a softened state. This he

Iron-
Making.

continues, at intervals, till the charge has subsided into a thick clotted sort of fusion. The furnace, at this period, is reduced to its lowest temperature; part of the furnace bars and fire are withdrawn, and the damper nearly shut; the puddler keeps stirring and moving the iron, backwards and forwards, which now begins to ferment and emit flashes of a bluish coloured flame (the carbon passing off in the state of carbonous oxyde). This operation is continued till these appearances pass off, and till the iron becomes less clotted, and begins, in the language of the workman, to dry. His exertions are redoubled, and soon the whole charge is reduced to the state of the finest saw-dust; it is now said to be dry, and so totally free from cohesion, that it may be moved about like as much sand. At this stage of the operation the grate bars are replaced; the fire repaired; the damper elevated; and the heat is in consequence increased, though gradually. The grains of iron become tipt with a snowy whiteness, resembling the welding of iron; they no longer repel each other, but begin to adhere in small masses; these increase in size as the temperature of the furnace is raised. When the charge begins to work heavy, the puddler selects a nucleus, and rolls it over and over upon the coalescing masses, till he has got it of the weight of 60 or 70 lbs.; he then places this on the flame side of the furnace, and anew he begins the operation of balling; repeating this till the whole charge is ball-ed up. A heavy iron instrument, called a Dolly, is then introduced into the furnace, and with this the balls are in succession beat to give them more cohesion in rolling. When properly heated, they are removed by tongs from the furnace, and slid along iron plates to the rolling machine. Here the lumps or balls are each, in succession, passed through rollers, grooved diagonally, acquiring, as they pass, additional cohesion and firmness, and assuming the form of a bloom. This is then presented to another pair of rollers, with flat openings or grooves, and rolled into a bar of three or four inches in breadth, and from half an inch to three-fourths of an inch in thickness. The whole operation of rolling one of the balls is performed in a minute and a-half, and pleases, while it astonishes the observer, by the rapid change which is thus passed upon matter the most unshapely and refractory. The whole time taken up to complete a charge from the puddling furnace is only from two to two and a half hours; the loss sustained is from 10 to 12 per cent. One furnace will discharge five or six heats in twelve hours, and make in one week from ten to twelve tons of rough bars. A set of rollers, moved by a thirty horse power, will rough down in a week 200 tons of such iron, and keep twenty puddling furnaces at work, for which three or four refineries or running out fires will be necessary. The material thus produced is called mill bars, and require another operation before they are finished. For this purpose they are carried to a pair of large steel shears, and cut into regular lengths, proportionate to the bar ultimately intended to be made. These pieces are then piled on each other in reference to the required thickness, as the cutting was to the requisite lengths, and are introduced into the reheating furnace. A welding

Iron-Making.

heat, by the flame of pit coal, is here brought upon them in the space of twenty minutes; they are then, one by one, taken to another set of rollers, similar to the first, and in the diagonal grooves each pile is brought down to a certain size; they are then put into the *finishing rollers*, and rapidly formed into bars of the most perfect form, and most accurate dimensions. At one of the most perfect works in this or in any country, one bar of iron *per minute* is finished for hours in succession, and one set of rollers have finished, in twelve hours, twenty tons of bar iron of the most perfect form. This formerly would have been full work for a week in any large manufactory of iron.

Such has been the extension of the iron trade in this kingdom, mainly owing to the great facility presented by puddling and rolling. That the Cyfarthfa Iron Works alone manufacture annually double the quantity of pig and bar iron made in the whole kingdom between the years 1740 and 1750, and a quantity nearly equal to one half of the whole make as it stood so late as 1788. Several iron establishments, on a smaller scale, finish from 200 to 300 tons; and few there are which do not manufacture regularly 100 to 150 tons weekly. In South Wales alone, there are now made yearly upwards of 80,000 tons of bars; and, in the whole kingdom, besides, nearly 120,000 tons more, making in all 200,000 tons. One of the paramount advantages of the present system is the facility and cheapness of rolling. Iron of every possible size and form can now be obtained at the common price of bars. The labour of the smith, in forging and drawing, are now almost unknown, and the price of his work proportionally reduced.

It is painful to know that, incalculable as have been, and are likely to be, the national advantages derived from the puddling process, which has given England the command of the markets of the world, Mr Cort, the inventor, after expending an ample fortune in bringing the system to perfection, died, and a respectable family survives, without having received any public acknowledgment of his services, or compensation for his losses.

IRON ORES.

To comprehend fully the theory of the separation of iron from its ores, it is necessary to examine and operate upon them in a smaller scale than that of manufacture. Ores of iron are in general mixtures of oxydes of iron with certain earths, in every possible proportion, which, if fused alone, without any addition, would be formed into glasses more or less dense, according to the quantity of iron they contained, and in which no trace of metallic iron would be found to exist. The simple principle, therefore, in reduction, is to add a substance to which the oxygen will unite, in preference to remaining with the iron, and such other substances with which the earthy matters of the ore would combine, on the same principle. Carbonaceous matter is found essential to perform the former part of this operation; and opposing earths contrary to each other in their natures, are found sufficient for the latter. Thus, if a common ironstone of this country is fused alone, in a common clay crucible, the result is a black glass of

iron. If charcoal be added in proportion to the quantity, the iron becomes separated. As the iron separates, it forms itself into a small spherule, under the glass. When charcoal is added in excess, that is, to the extent of one-fifth or one-seventh, the weight of the ore, three-fourths of the iron, will be found revived. The deficient produce remains in the glass, or unites to the superfluous charcoal, forming a magnetic carburet of iron. If there has been an excess of clay in the ore, the glass will be found black, opaque, and concave on the surface. If of silex, deep bottle green, with brownish-coloured cells, around the metallic button.

If this experiment is repeated with one-third or one-fourth the weight of the ore of lime, other circumstances being alike, the carburet of iron will disappear, the glass will be found dense, comparatively transparent, and the produce in iron greatly increased. If the same ore alone was put into a crucible, mixed with carbonaceous matter in its texture, or into one chiefly composed of black lead, fully one-half the produce of the ore would be revived. Or, if masses of the same ore were deoxygenated by a prolonged cementation with charcoal, their subsequent fusion, *per se*, even in a common crucible, would yield five-eighths the whole iron contained in the ore; and, if fused in a black lead crucible, seven-eighths of the whole iron would be reduced to a metallic state.

When the first portions of iron are extracted from an ore, with a minor proportion of charcoal, the resulting globule is always in the state of soft or ductile iron; as the dose of carbon is increased, the iron subsequently passes through various states of steel and common crude iron; and, if properly conducted, into that of the richest carburet of iron. The quantity of reduction performed by the charcoal is various at various stages. In the first place, all the charcoal is employed to unite with the oxygen, and a certain additional quantity beyond this must be used, before iron is produced. After this the rate of reduction is increased, till more than one-half the iron is revived; it then falls off, upon the well-known ground that the last portions are always most difficult to extract. Much larger doses of charcoal, in proportion, are necessary; and it is essential to perfect separation that not only all the oxygen be removed from the ores, but that the resulting iron itself should take up a considerable portion of the carbon so added. The table subjoined will more clearly illustrate these hitherto unknown facts.

If a calcareous ore is subjected to fusion in a clay crucible, it will melt with facility, in proportion to the quantity of iron united with the lime, and form a black shining lustrous glass. If charcoal is added, the iron will separate; but if it is added in excess, the ore will become refractory, and not melt. The same ore, thrown into a black lead crucible, will sink down into a rough mass, without any separation of iron. If an argillaceous substance is added, fusion and a fine glass will ensue; and if a proper quantity of charcoal is present, the same will be transparent. If the argillaceous earth is diminished without any change in the charcoal, a pure white porcelain will be obtained over the iron, similar to, though much

Iron-Making.

Iron-Making.

more perfect than the cruddley or limy cinder of the blast-furnace.

The fusion of a siliceous ore of iron, *per se*, affords a highly polished shining glass of iron, the fracture of which frequently decomposes light. On the addition of charcoal, an imperfect ropy fusion is obtained. The siliceous matter is then resolved into a deep brown or yellowish glass, streaked with glass of iron, and the separated iron thrown about the crucible in a state of small globules of a silvery colour, which are generally understood to be an alloy of iron and the metal of silex. When the silex exists in small quantities, compared with the oxyde of iron, as is the case with the Lancashire and Cumberland ores, the whole of the iron may be revived with charcoal alone, and the earthy matter remain unfused, but in an agglutinated state.

Ores of iron are in themselves frequently united with such a mixture of earths, as to render, with the proper dose of carbon, the most transparent glasses, and iron of the most perfect quality. If the ores are rich, an inconveniency is sustained, by the metallic button being on its upper surface exposed without a covering of glass. This not only tends to decarbonate the iron, but, if in a state of ebullition, allows it to be projected against the sides and cover of the crucible, and makes the product difficult to ascertain.

The following is a table or abstract of a set of experiments, made with a common blast-furnace ironstone, in which experiments, lime, deprived of its carbonic acid, predominated as a flux, but to which other substances were added, to prove their effect in facilitating or retarding, with the same or different proportions of charcoal, the reduction of the metal from the ore. The ore itself had been previously assayed for carburated cast iron, and yielded 46 per cent.

Table of the Reduction of Ironstones.

	Weight of the Mixture Grains.	Grs. of Iron obtained	Parts in 100.	Iron revived for each Grain of Charcoal	Grs. of Iron in the Glass	Per Cent. age of Iron in the Glass

DESCRIPTION OF THE PLATES.

PLATE LXXXVIII.

Fig. 1, Represents the section of an air-bloomery furnace, similar to that used by the Africans, as stated by Mr Park in his *Travels*.

Fig. 2, A horizontal section of the same furnace across the openings, used for the admission of air, and discharging the furnace.

Fig. 3, Represents a section of the old blast-bloomery, with its bellows and lifters, which was universally used for the manufacture of malleable iron before the invention of the blast-furnace, and the discovery of the manufacture of pig-iron.

Fig. 4, A ground plan of the same furnace, showing the bellows and blast pipes, and A, the opening which was regularly broken down at the end of each heat, to remove the bloom of iron from the bottom to the hammer. These blows were worked in a very simple manner, without the assistance of levers, by a man alternately depressing the upper board of each, by merely treading thereon, which, in its turn, was again elevated by means of the lifter and counter weight. The stream of air, in this way, was prolonged with but little pause or interval.

Fig. 5, Is a section of the building, and interior of the charcoal blast-furnace, about the time of its first application for the purpose of making pig-iron. The remains of a furnace similarly constructed were accidentally discovered, in making an excavation, about eight years ago, in Dean Forest. This furnace, along with many others in ancient times, belonged to the Crown, were called *King's Furnaces*, and were probably used for the purposes of smelting, with the cord-wood of the forest, the King's share of the iron ore obtained from the mines.

From its situation on the margin of a small stream, and the remains of the water course, the bellows must have been worked by means of a small water wheel. The height of this furnace, from A to B, judging by the dimensions of the hearth and boshes, which were found entire, could not have exceeded 20 feet. The height of the hearth, from A to C, 4 feet, and the height of the boshes, from C to D, 2½ feet. The length of the hearth, from e, the back wall, to f, the front of the dam-stone, 4 feet.

G, G, The lining, constructed of thin beds of an infusible species of sandstone.

Iron-Making.

H, The hearth, composed of stronger beds of the same species of sandstone, called *land-stone*.

Fig. 6, Is a section at right angles of that part of Fig. 5, comprising the space from D to A, in which the letters correspond, showing the blowing orifice called the twyre, the twyre-arch, and the three cast iron bearers called "*soms*," for supporting the same.

Fig. 7, Is a horizontal section of the same furnace at D, the top of the boshes, Figs. 5 and 6, showing the quadrangular form of the interior, which was common to charcoal furnaces at that time, and in which the letters of reference also correspond.

This furnace was destroyed at the commencement of the civil commotions in the reign of Charles the First, and was never afterwards rebuilt.

PLATE LXXXIX.

Fig. 1, Represents a section of one of the largest charcoal furnaces, such as are now in use, and which is also applicable to the making of coke pig-iron.

In this drawing the exterior building is omitted, and no more retained than is necessary to give a correct view of the interior of the furnace, and the arrangement of the blowing apparatus.

Fig. 2, Is a ground plan or horizontal section of the above furnace at the top of the twyre openings, exhibiting A, A, A, the twyre arches.

B, B, B, The blast pipes; the two dotted lines showing their communication with each other through the pillars of the furnace, and with the blowing machine.

C, The *fald*, fauld, or working-arch, by which the hearth is approached, and the operations of working, flowing the cinder, and tapping off the metal, are performed.

D, A longitudinal view of the hearth from the back-wall to the front of the dam stone.

E, The dam stone, about eighteen inches high, over which the *cinder* or scoria flows, and which closes up the front of the furnace, with the exception of the space at *f*, called the *tapping-hole*. This is opened from time to time to allow the metal to flow out. The letters in this plan correspond with those in the perpendicular section, Fig. 1.

Fig. 3, End view of the blowing machine, consisting of three cylinders, calculated to discharge the air both ways. The pistons are successively moved by means of three cast iron beams.

K, K, K, The three working beams (two of which only are seen), connected with a triple crank or lying shaft, I, I, I. To this crank-shaft is attached a small pinion wheel G, which is worked by the large spur wheel H, placed on the shaft of the water wheel.

Fig. 4, Is a ground plan of the former, showing the crank-shaft I. The tops of three blowing cylinders L, L, L, with the valve openings N, N, N, the main valve boxes and blast pipes M, M, M. The letters of reference correspond with those of Fig. 3.

Fig. 5, A view of a refinery furnace, or running-out-fire, with its blowing apparatus.

O, The general appearance of the furnace.

P, The front plate of the hearth, with the tapping holes.

Q, The cistern into which the water of the tue-irons empties itself.

R, A reservoir for the supply of the tue-irons with cold water.

S, The tue-iron pipe, which conveys a constant stream of water to prevent the tue-irons from burning. The tue-irons for this purpose being made double, leaving a hollow space all round for the water.

T, The nose-pipe, inflected for the purpose of discharging, when melted, a current of air upon the surface of the metal, to produce refinement or decarbonization.

U, The blast box, containing the valve for regulating the air.

V, The blowing cylinder.

W, The blast pipes for conveying the air into the inverted water regulating cistern X.

Y, Y, The space for the ascent and descent of the water, for restoring the equilibrium, giving smoothness to the motion of the engine, and rendering the current of air more equable throughout.

Fig. 6, Represents a ground plan of the blowing machinery, and two running-out fires.

Z, Z, The hearths in which the iron is melted and refined.

t, t, t, The water tue-irons, two of which are necessary for each fire. The other letters of this plan correspond with those of Fig. 5.

Fig. 7, An enlarged section of the water tue-iron, with its pipes of supply and discharge, *s* and *r*.

Fig. 8, End view of the above tue-iron, showing the two holes for receiving the pipes *s* and *r*, and the size of the blowing orifice at the smaller end. It is the same with that referred to under the letter *t*, in Figs. 5 and 6.

PLATE XC.

Fig. 1, A section of a coke pig-iron furnace, with its twyres and twyre-arches, similar to what are at this present time used in South Wales, where upwards of one hundred tons of pig-iron have been produced weekly from one furnace. The extreme height of this surface from the bottom at A, to the filling place at B, is 50 feet. The height of the hearth, from A to C, 8½ feet; from C to the top of the boshes at D, 8½ feet. The diameter of the hearth, from A to C, increases from 3 feet to 3½ feet. The extreme width at the top of the boshes D, 18 feet. The diameter of the charging place, B, 6 feet.

E, E, E, E, The lining composed of a double circle of fire bricks, about 15 inches long, each, with a space for an intermediate packing of sand.

F, F, The hearth, constructed of large blocks of breccia or plum-pudding stone, from over the mountain limestone measures.

G, G, The twyres or openings, by which the blast is discharged into the furnace.

	Cubic Feet.
Contents of this furnace,	5015
Ditto, the large charcoal ditto,	1017
Ditto, small ditto,	428

Fig. 2, A view of a double power steam-engine for the purpose of blowing furnaces, the steam cy-

Making.

cylinder of which is 60 inches diameter, the blowing cylinder 100 inches diameter; length of the stroke, 9 feet; travels 12 double or 24 single strokes per minute.

	Cubic Feet.
Capacity of the blowing cylinder,	486½
Quantity of air discharged at the rate of 24 cylinders per minute,	11760
Density of the blast, 3 pounds per square inch.	

This engine is capable of blowing four furnaces at the rate of 3000 cubic feet of air per minute for each, and making from 250 to 280 tons of pig-iron weekly.

A, The steam cylinder.

B, The blowing cylinder.

C, The cold water cistern, with its ends taken off to show the air-pump *p*, and condensing cylinder *s*.

D, The lever wall for supporting the cast-iron beam.

E, The working beam and parallel motions to which the steam and blowing piston rods are attached.

F, The steam cylinder pedestal of ashlar work.

G, The pedestal of the blowing cylinder, serving also to load the air receiver, *x*, beneath.

H, H, Spaces for the water to ascend when displaced by the compressed air within the inverted cistern, *x*. The difference of level, between the surface of the water in the interior and exterior of this cistern, when the engine is at work, will always be in the ratio of the density of the blast. In this instance, the surface of the outside water will be nearly seven feet higher than that of the water within the regulating cistern.

I, The branch blast pipe for communicating with the water regulator.

Fig. 3, A ground plan of the steam cylinder, pedestal, cold water cistern, air pump, condenser, and lever wall, the letters of which correspond with those in the elevation.

Fig. 4, Is a ground plan of the blowing cylinder, blast-pipes, pedestal, and water regulator.

K, K, K, K, Represent the openings or valve spaces in the top of the blowing cylinder, for admitting the air during the descent of the piston. A similar number of these openings with valves affixed, are placed in the bottom of the cylinder for admitting the air during the ascent of the piston.

L, The blast box, containing the upper main valve for preventing the return of the air during the descending stroke. A similar box, containing the lower main valve, may be seen at L, in the elevation (Fig. 3), for preventing the return of the air, during the ascending stroke. The other letters in this figure correspond to those in the elevation.

PLATE XCI.

Fig. 1, A ground-plan of a mill for rolling various sorts of iron.

A, The crank by which motion is communicated to the machine, when steam is the moving power.

B, The large spur-wheel, the teeth of which work into those of

C, The pinion wheel, to the axis of which the roller pinions are coupled.

D, The fly-wheel, of cast iron, 24 feet in diameter.
E, The small spur-wheel for imparting motion to F, F, F, Three pinions, and their respective shafts, to which the rollers, or cutters, are occasionally coupled.

G, G, G, G, The main cills, which are heavy masses of cast iron.

H, The puddling or roughing-rolls for compressing into regular form the balls of iron from puddling furnace.

I, Rollers for finishing flat bars.

K, Rollers for forming square bars of iron.

L, Pinion and rollers for hoops or plate iron.

M, Pinion and cutters for slitting rod iron.

N, N, N, N, N, Roller and cutter cills made of cast iron.

O, O, Eccentric wheels for working the cutting sheers. P. (Fig. 2.)

Fig. 2, An elevation of that part of Fig. 1, comprising the crank-shaft, spur wheel, fly wheel, and cutting sheers, P; the other letters correspond to those in the ground plan.

Fig. 3, An elevation of that part of Fig. 1, including the small spur wheel, three adjoining pinions, fly wheel, and main cill. The letters correspond with those of the plan. (Fig. 1.)

Fig. 5, Rollers for sheet, plate, or hoop iron.

Fig. 13, An enlarged view of one of the roller housing frames, with the rollers, plummer blocks, brasses, and adjusting screw, corresponding to *t, t, t*, in Figs. 1 and 5, and Fig. 4, Plate XCII.

Fig. 15, Ground plan of a water wheel bar iron forge, with two hammers and anvils.

A, The water wheel and shaft.

B, Forge hammer, with a cast iron helve and supports, lifted by projecting pieces of cast iron, on the end of the water wheel shaft, called *cams*.

C, A forge hammer, with a wooden helve, lifted by similar means. Only one of the hammers can be worked at a time, and the latter only when the motion is reversed, and in cases where, instead of the water wheel, a steam-engine is the moving power.

Fig. 17, An elevation of the forge (Fig. 15), showing the water wheel, cam-ring, cams, standard, hammers, anvils, anvil blocks, and framing.

F, F, The anvil blocks and anvils.

G, The standard for supporting the end of the water wheel shaft.

H, The spring beam corresponding to Fig. 16, Plate XCII.

I, The cam-ring and cams. The other letters in this figure correspond to those on the ground plan.

PLATE XCII.

Fig. 4, An elevation of three different sets of rollers, with their pinions, housings, cills, and underground buildings.

a, Rollers for the extension of square bars.

b, Rollers for forming and finishing flat bars.

c, Rollers for making round or bolt iron.

Fig. 6, An enlarged view of the rollers, pillar-bed, and pillars, with their screws, which are broken off for the convenience of the plate. This figure is the same as that of *r, r*, Fig. 1, in Plate XCI. and of *r, r*, in the centre rollers, Fig. 4, Plate XCII.

(K. K. K.)

I T A L Y.

THE History of *Italy*, down to the year 1789, is given under the article *ITALY*, in the *Encyclopædia*; and the events of importance, which have subsequently occurred, will be found under our articles *AUSTRIA* and *FRANCE*. In the present article, we shall confine our attention to the general features of the country, its agriculture and manufactures, and the political situation and manners of its inhabitants. The limits within which we are necessarily confined oblige us to exclude all descriptions of the cities, antiquities, and monuments of the fine arts, in this interesting country. The recent *Travels* of Forsyth, Eustace, Williams, and Matthews, are so copious on these topics, as to leave hardly any thing to be added to what they have collected; and, without attempting to abridge what they have written, we shall endeavour to give some information on subjects which have not fallen so particularly under their consideration.

CHAP. I.

Divisions—Rivers, Lakes, Mountains.—Population.—Climate.—Malaria.—Classes into which Society is divided.—Manufactures.

Italy comprises four great divisions; in each of which the face of Nature, in the mode of cultivation, and the condition of the people, is very different from what is in the others.

Divisions.

The *first* of these embraces the vast plain which lies between the Alps and the Appenines; and extends from Coni on the west, to the Adriatic on the east. It is bounded on the south by the Appenines, which, branching off from the maritime Alps, run in a south-easterly direction to the neighbourhood of Lorretto; and on the north by the chain of the Alps which presents a continued face of precipices from sea to sea. This rich and beautiful plain is, with the exception of a few inconsiderable hills, a perfect level; insomuch, that for 200 miles there is not a single ascent to be met with. Towards its western end, in the plain of Piedmont, the soil is light and sandy; but it becomes richer as you proceed to the eastward, and from Lodi to Ferrara is

composed of the finest black mould. It is watered by numberless streams, which descend from the adjacent mountains, and roll their tributary waters to the Po; and this supply of water, joined to the unrivalled fertility of the soil, renders this district the richest, in point of agricultural produce, that exists in Europe. An admirable system of cultivation has long been established in this fertile plain; and three successive crops annually reward the labours of the husbandman. (*Chateauvieux*, 12; *Young*, 2. *passim*.)

The *second* extends over all the declivities of the Appenines, from the frontiers of Provence to the southern extremity of Calabria. This immense region comprises above half of the whole superficial extent of Italy, and maintains a very great proportion of its inhabitants. It everywhere consists of swelling hills, rapid descents, and narrow vallies, and yields spontaneously the choicest fruits. The olive, the vine, the fig tree, the pomegranate, the sweet chesnut, and all the fruits of northern climates, flourish in the utmost luxuriance on the sunny slopes of Tuscany and the Roman States; while, in Naples and Calabria, in addition to these, are to be found the orange tree, the citron, the palm, and the fruits of tropical regions. The higher parts of these mountains are covered by magnificent forests of sweet chesnuds, which yield subsistence to a numerous population, at the height of many thousand feet above the sea; while, at the summit, pastures are to be found, similar to those of the Cheviot Hills in Scotland.

The *third* region comprises the plains which lie between the Appenines and the Mediterranean, and extends from the neighbourhood of Pisa to the mountains of Terracino. This district, once covered by a numerous population, and cultivated in the most careful manner, is now almost a desert. It is the region of insalubrious air; and no means have yet been devised by which it is possible to enable the human race to flourish under its pestilential influence. After leaving the highest state of civilization in Florence or Rome, the traveller is surrounded

Italy. ed to find himself in the midst of vast plains, over which numerous flocks of cattle wander at large, under the care of shepherds mounted on horseback, and armed after the fashion of the steppes of Tartary. This division includes under it all the plains which lie between the Apennines and the Mediterranean in the Neapolitan territory, among which the Maremma of Pestum is most conspicuous; and nothing but the vast population of Naples prevents its celebrated Campagna from relapsing into the same desolate state.

The fourth great division comprehends the plains which lie to the eastward of the Apennines, in the kingdom of Naples, and is bounded by the Adriatic Sea on the one side, and the irregular line of the mountains on the other. It is in some places from 50 to 100 miles broad, and in others the mountains approach the sea shore. The country is flat, or rises into extensive downs, and is cultivated in large farms where it is under agricultural management; but a great proportion is devoted entirely to pasturage. Immense forests of olive are to be met with in this remote district, and the hills are covered with vines, and oranges, and other fruits, with corn growing under them. (Williams's *Travels*, II. 137, 138.)

Rivers.

The principal rivers are, the Po, the Arno, and the Tiber. The first of these drains the whole plain of Lombardy, and receives in its course all the torrents which descend from the southern side of the Alps and the northern front of the Apennines. The quantities of sand and gravel which these torrents bring down during the autumnal and winter rains, renders them extremely destructive to the soil in their vicinity, which is generally overwhelmed, often for the distance of miles on each side, by a load of stone and gravel torn from the higher parts of the mountains. To guard against the devastations of the Po, in its progress towards the Adriatic large mounds have been constructed on each side of the river, in the Lombard and Venetian territories; and these mounds have been progressively raised as the channel of the river was filled by the debris of the mountains from which it is supplied. The consequence has been, that not only this great stream, but also the Tessino, the Brenta, the Tagliamento, and the Adige, in many places, flow in a channel greatly elevated above the adjacent country; and the same may be observed of many other torrents in their course from the Apennines to the ocean. (Young, I.; Chateauxvieux, 80.) The *Laguna* of Venice are formed by the sand and earth which these great rivers have brought down to the Adriatic; and which has accumulated at their mouth, from the combined influences of the stream and tide. (Daru, *Hist. de Venise*, I. 10, 11.) The Arno runs in a north-westerly direction from the centre of the Apennines towards Pisa, and receives, in its course, all the streams which descend from the western declivity of the Apennines. Its waters are gathered with religious care by the industrious peasantry of Tuscany, and by an infinite number of small canals, made to fertilize almost every field in the delightful valley, to which it has given its name. (Chateauxvieux, 81.) The Tiber rises in the recesses of the mountains in the north of the eccle-

siaistical state, and, swelled in its course by the torrent which is precipitated over the rocks of Terni, and that which adorns the classical scene of Tivoli, winds through the deserts of the Campagna, and flows, in a majestic current, through the walls of Rome. In the autumnal months it is liable to frequent and sudden inundations from the torrents which fall in the mountains; and, even in summer, its waters are so discoloured, as to justify the ancients in calling it *flavum Tiberim*. The most remarkable rivers in the Neapolitan territory are the Gariglione and the Sele; the former of which falls into the sea, near Mola di Gaeta, while the latter descends from the wooded mountains behind Eboli, and glides through the deserted Maremma of Pestum.

Italy.

There are few countries which can boast of a greater number of Lakes than Italy. Those of Maggiore, Comò, and Lugano, are assembled at the foot of the mountains immediately to the north of Milan; and combine, perhaps, a greater variety of beauty than any other lake scenery in Europe. They are surrounded by the lower Alps, whose summits bear the character of the chain to which they belong, while their sides are clothed with the luxuriant woods, and rich vegetation, which indicate the warmth of an Italian sun. Innumerable villages, each adorned with a spire, and composed of white cottages, peep through the verdant foliage, with which the steep declivities of the mountains are covered, or are perched on the side of rocks seemingly inaccessible to human approach. On these delightful banks, the olive, the vine, and the sweet chesnut, flourish in the utmost luxuriance; while, in the warmer aspects, the orange and the citron are nursed by the inhabitants, as a mark of the mildness of their climate. The Lago di Gardo is a great expanse of water, 40 miles in length, the lower extremity of which descends into the plain of Lombardy, while its northern end is lost in the recesses of the Alps. Its banks exhibit the same singular combination of extensive woods with innumerable spires and white villages, which characterize Maggiore and Como; but its expanse is too great to admit of the romantic beauties which have rendered these lakes so celebrated. The lake of Varese is an oval sheet of water, surrounded by the sunny hills, which mark the melting of the Alps into the plains, and on which the choicest fruits, and the richest crops, rewards the industry of the husbandman. In the centre of Italy, the lake of Thrasymentis is interesting, not merely from the memorable battle fought there, but from the smiling aspect of its wooded and peopled banks; while that of Bolsena presents a totally different character, being shut in by dark forests of pine and oak.

The only range of mountains which properly and exclusively belongs to Italy is the Apennines; and they extend over more than half of the country. Their height is very various; in the vicinity of Genoa they rise to about 4500 feet; above Pontremoli, on the borders of Tuscany and Lombardy, they reach 5500 or 6000 feet, and the great ridge which stretches from Bologna by Valombrosa to the south-east, rises in some places to between 6000 and 7000.

Mountains.

Italy. They are not, in general, very rocky; at least, it is only in their higher eminences that this character appears. Their lower parts everywhere almost are covered with fruit trees, under the shade of which, in the southern exposures, crops of grain are brought to maturity. Higher up, the sweet chestnut covers the ascent, and supports an immense population, at an elevation above the sea, where no food for man could be procured in our climate. The pine, the beech, and the fir, occupy those higher regions, in which are Valombrosa, Laveruia, and Camaldoli; and at the summits of all, the open dry pastures furnish subsistence to numerous flocks. (Forsyth, 92; Chateaufieux, 57.) This great capability of the Appenines to yield food for the use of man, is the cause of the extraordinary populousness of its slopes. In the remotest recesses, the traveller discovers villages and towns: and on the face of mountains, where the eye, at a distance, can discern nothing but wood, he finds, on a nearer approach, every spot of ground carefully cultivated. The villages and towns are commonly situate on the summits of eminences, and frequently surrounded by walls and towers; a practice which began in the turbulent periods of the Italian republics, and has been since continued from the dread of *Malaria* in the bottom of the valleys. It adds greatly to the picturesque effect of the mountain scenery, and gives it a character altogether peculiar. In the Tuscan states, the lower ranges of the Appenines have been the object of the utmost care, and of an almost inconceivable expenditure of capital. They are regularly cut in terraces, and, whenever an opportunity occurs, water is brought from the adjoining rivers, and disseminated in little covered canals to every field, so that the whole valley is, as it were, covered with a network of small streams, which convey their freshness all around. The olives and figs which flourish in this delightful region are foreign to the Tuscan soil; there is not a tree there which is the spontaneous production of nature; they are all planted and pruned by the hand of man.

Climate.

The Climate of Italy is known to all the world. Poets and travellers, from the earliest times, have united in celebrating its enchanting air, and its cloudless sky. During the spring these praises are, indeed, deserved; but in summer and autumn, the excessive heats render it disagreeable to venture out in the forenoon, and foreigners insensibly fall into the Italian custom of taking exercise only in the dusk of the evening. Even the peasants yield to this universal propensity, and for a few hours at noon repose from their labours. The thermometer, in summer, often rises at Florence and Rome to 90° of Fahrenheit; at Naples, it is sometimes as high as 96°. From 75° to 85° is the usual heat of Italy in summer; from 40° to 70° in winter. Frost and snow rarely occur in the plains, though always on the mountains. Delightful as it is, however, this climate is not without its disadvantages. In the close of the year immense torrents of rain fall, often with little interruption for weeks together; and the unhealthiness of the atmosphere, almost every where to the south of the Appenines, induces such of the

inhabitants of the plains as have the means, to migrate, during the months of summer and autumn, to higher situations. Yet, with all this, it may safely be affirmed, that the clear air and sky of Italy is a source of enjoyment, which, to those who have not witnessed it, can hardly be imagined. Independently of its other influences, it gives an indescribable charm to the productions of the earth. Innumerable plants of aromatic fragrance fill the air with their sweetness, and seem to flourish best in those sterile situations, where nature can produce no food for the use of man. Their fragrance in the spring extends to a great distance from the rocks on which they grow; and the traveller, as he sails in the night from La Spezia to Genoa, inhales the perfumed air, wafted from the shore by the nightly breeze of these warm climates. The activity of the Italians in former times, proves that their climate is quite consistent with the most energetic and industrious habits of life; while there can be no doubt, that the delicious air which they breathe, and the beautiful objects which are continually before their eyes, have had a material effect in producing that taste in the fine arts, by which they are distinguished from every other people of modern Europe.

Italy.

There is one peculiarity of the Italian climate *Malaria*, which is well deserving of notice, the *Malaria*, which, during the autumnal months, renders the greater part of the plains so dangerous to the inhabitants and to foreigners. This pestilential air is little known in the western parts of the plain of Lombardy, but it is felt in the vicinity of the rice grounds of Pavia, as well as at the northern extremity of the Lake of Como. The neighbourhood of Ferrara, and the country which lies between it and Bologna, is, owing to the malaria, one of the most unhealthy of Italy; Venice experiences its fatal effects in the autumnal months, and the shores of the Gulf of Commacchio is hardly habitable during the heats of summer from the same cause. But it is principally to the south of the Appenines that this dreadful evil predominates. The whole plain of Tuscany, between the mountains and the sea, is neglected, from the insalubrity of the atmosphere. In the Roman States, the *Campagna* of Rome, and the Pontine Marshes, are absolutely deserted; and the ravages of the malaria are so much dreaded in the city itself, that all the wealthy inhabitants migrate during the autumnal months to Fiescata and Albano, whose elevated situations place them above its reach. The *Campagna* of Naples, notwithstanding its thick woods and rich cultivation, is not exempt from it; and the shores of Pazzuoli and Baiæ are in some places so dangerous, as to occasion certain death to those who, during the warm weather, are exposed to the influence of the night air. No army has ever yet besieged Naples in summer without having its ranks thinned by the *malaria* fever. The French army, which capitulated to Charles V. in 1528, was reduced from 28,000 to 4000 in the course of a few days, by being encamped before they were embarked on the shores of Baiæ. The beautiful plain in which Pæstum is situate exhibits a deserted waste from the same cause, and the inhabitants who dwell among its ruins, or on the

Italy.

melancholy shores of the Sele, prove by their wan and emaciated appearance that habit has no tendency to enable the human frame to bear its effects. Universally, indeed, to the south of Florence, the plains and low grounds are more or less subject to malaria, and it is chiefly to this cause that the common practice of building villages on the summits of the mountains, by which the picturesque appearance of the country is so much enhanced, is to be ascribed.

The fevers which this pestilential air produces, commence in July, and continue till the heavy rains of September and October have precipitated the noxious vapours, and restored the salubrity of the atmosphere. During the intervening months it is in the highest degree dangerous to be exposed to the night air; and the marshes should not be traversed even during the day, without taking every possible precaution. So strongly are the inhabitants of the country impressed with this idea, that the shepherds who tend the flocks in the Campagna, resort to Rome during the night, and seek under its walls and houses an asylum from the danger which they would run in the open country. The best advice that can be given to travellers is, to avoid the dangerous regions during the autumn months; but if they are obliged to visit them at that season, they should never travel at night, and take care to close the windows of their rooms from sunset till they rise next morning. It is advisable to live rather fully when in the unhealthy districts; and if the *Maremma* are to be crossed, bark and Port wine, and a few glasses of *Lachrymæ Christi*, should be taken before setting out in the morning. Intoxication, however, of the slightest kind, is cautiously to be avoided, as exposure to the night air when under its influence is almost certain death. By observing these precautions, the dangers of the climate may be effectually guarded against, and the traveller may visit the environs of Rome and Naples even during the unhealthy season, without running any considerable risk. If he is seized with the malady, bark and Port wine, as in the English ague, are generally employed.

Population. The Population of Italy has been ascertained by a very accurate census, taken under the authority of the French Government, during the sway of Bonaparte; and it shows an aggregate of 16,419,000 souls, or 1237 inhabitants to every square league,—a population more dense than that of France, or the British Isles. When it is recollected how large a proportion of the country is rendered uninhabitable by the bad air, this shows how dense must be the numbers in those districts where man is able to exist. The country is 700 miles long, from the mountains of Aosta to the extremity of Calabria; in Lombardy, it is 350 miles broad; in the central parts, about 140; and at the extremity of Calabria, only 75.

This population is distributed as follows:

I. Kingdom of the Two Sicilies.

	Square Miles.	Inhabitants.
Naples,	31,000	4,963,000
Sicily, with the lesser isles,	12,600	1,635,000
Total,	13,600	6,618,000

II. Kingdom of Sardinia.

	Square Miles.	Inhabitants.
1. Piedmont, including Nice,	7,900	1,750,000
2. Duchy of Montserrat,	900	186,000
3. Part of Duchy of Milan,	3,300	556,000
4. Territory of Genoa,	2,300	532,000
5. Savoy,	3,800	450,000
6. Sardinia,	9,200	520,000
Total,	27,400	3,994,000

III. Kingdom of Lombardy and Venice

1. Province of Milan,	8,310	2,082,000
2. Province of Venice,	9,950	1,982,000

Total, 18,920 4,014,000

IV. Ecclesiastical State,

14,500 2,346,000

V. Tuscany, including Elba,

8,500 1,180,000

VI. Duchy of Parma, Placentia, and Guastalla,

2,280 377,000

VII. States of Modena.

1. States of Modena, Mirandola, and Reggio,	1,740	332,000
2. Duchy of Massa and Carrara,	320	38,000

Total, 2,060 370,000

VIII. Duchy of Lucca,

420 138,000

IX. Republic of St. Marino,

40 7,000

Grand total of Italian States,	117,090	19,044,000
Deduct Sicily, Sardinia, and Savoy,	25,600	2,625,000

Italy Proper, 91,490 16,419,000
which is 180 to the square mile.

The following is a table of the great towns in the great Italian States:

Kingdom of the Two Sicilies.

	Inhabitants.
Naples,	330,000
Palermo in Sicily,	130,000
Messina in do.	70,000
Calama in do.	60,000
Bari,	18,000

Kingdom of Sardinia,

Turin,	65,000
Genoa,	76,000
Cagliari,	35,000
Alessandria,	30,000
Nice,	19,000
Casali,	16,000
Chamberry,	12,000

Kingdom of Lombardy and Venice.

Milan,	130,000
Venice,	116,000
Verona,	42,000
Brescia,	34,000
Padua,	31,000
Mantua,	23,000

ITALY.

Italy.

Cremona,	Inhabitants.	23,000
Bergamo,		20,000
Ecclesiastical State.		
Rome,		134,000
Bologna,		64,400
Ferrara,		24,000
Ancona,		18,000
Duchy of Tuscany.		
Florence,		75,000
Leghorn,		50,000
Sienna,		24,000
Pisa,		17,000
States of Modena.		
Modena,		20,000
Reggio,		13,000
Massa,		9,800
Carrara,		8,500
Duchy of Parma.		
Parma,		28,500
Placentia,		15,000
Lucca,		17,600
St Marino,		6,000

The comparative density of the population in these different states is as follows:

	Inhabitants.	
Kingdom of Naples,	160	to the square mile.
Kingdom of Sardinia,	146	
Do of Lombardy and Venice,	211	
Ecclesiastical State,	168	
Tuscany,	139	
Duchy of Parma,	121	
States of Modena,	190	
Duchy of Massa,	118	
Duchy of Lucca,	328	
Republic of St Marino,	175	

Population at Different Periods. That the great towns of Italy were much more populous at former periods than they now are cannot be doubted. Mr Gibbon states the population of Rome, in 1765, at 161,899. (Gibbon's *Works*, XII. 429.) Chateaubvieux estimates its population, in 1791, at 166,000. The extraordinary defalcation since this period, being 32,000 in twenty years, is owing partly to the increase of the malaria; partly to those causes, which, during the war, destroyed the sources of its prosperity. Since the peace, it is understood that its population has considerably increased, principally in consequence of the concourse of travellers, and the resumed residence of the Papal government.

Florence, which now can number only 75,000 souls, contained, at the close of the fifteenth century, 150,000, and in 1496, ventured to measure strength with Charles VIII. at the head of all the feudal power of France. (Sismondi, XII. 168.) At that period, and for nearly a century before, it had engrossed the commerce of the south of Europe, and its private merchants numbered all the kings of Europe among their debtors. (Villani, 824.) Pisa, at a still earlier period, contained 140,000 inhabitants, whereas its population is now reduced to 17,000. (Hallam's *Middle Ages*, I. 454.) When

the rival fleets of Genoa and Pisa fought at La Meloria, in 1284, each bore as many sailors as manned the English and French fleets at Trafalgar, and 11,000 of the vanquished party were carried off to the Genoese prisons. (Sismondi, IV. 22.) Venice, at one period, numbered 48,000 sailors in her fleet, whereas the whole population capable of bearing arms does not now amount to nearly that number. The immense extent of the buildings in most of the towns of Tuscany, as Sienna, Pistoia, &c. which are hardly inhabited, prove how great the numbers of the inhabitants were in former, compared to what they are in modern times. The latter of these cities formerly contained 40,000 souls;—at present it hardly possesses 8000. (Chateaubvieux, 82.)

Notwithstanding this great diminution of the population of the Italian towns, there is reason to believe, not only that the inhabitants of Italy, upon the whole, have gone on progressively increasing during all this period, but that they are at this moment more numerous than they were at any former period of its history, not excepting the most flourishing periods of the Roman empire. (*Ibid.* 300.) The population of Tuscany was calculated, about the year 1780, at 1,000,000: it is now considerably above that number. (Paoletti, 58.) In Friuli, the population, in 1581, was 196,541; and 1755 it contained 342,158 inhabitants. In the district of Padua there were, in 1760, 240,336 souls; in 1781, 288,300. In short, if many parts of Italy are not now so populous as they were during the flourishing periods of her republics, it is more than probable that the deficiency is compensated by the great agricultural population in other districts; or at least that population has advanced rapidly during the last hundred years, to fill the blanks occasioned by the misfortunes of the sixteenth century.

The cause of this remarkable decrease among the inhabitants of the great towns, and increase in the agricultural population, is to be found in the entire destruction of commercial and manufacturing industry, which followed the destruction of the republics, and the establishment of the Spanish dominion over the whole country, in the early part of the sixteenth century. (Sismondi, XVI. 158.) The wealth of all the commercial cities was, in consequence, turned to the purchase of land, the only remaining employment in which it could find any profit; and so universal was the transference, that, before the close of the sixteenth century, the commercial was every where converted into a landed aristocracy.

The great quantity of capital which was thus directed from commercial industry to the purchase of land, contributed in some degree to produce that minute division of estates which distinguishes Tuscany, and is observable even in the plains of Lombardy. (Chateaubvieux, 81, 293.) So large a proportion of her people has, since the loss of Italian independence, been directed to rural pursuits, that it is now calculated at thirteen out of the seventeen millions of which her population consists.

The Italian people may be divided into five different classes. 1. The proprietors of land, or *Possidenti*, as they are called. 2. The merchants. 3. The People.

ITALY.

manufacturers and artificers. 4. The professional classes. 5. The cultivators of the soil.

The *first* of these classes, that of proprietors of land, is extremely numerous, but by no means wealthy. The extreme subdivision of land, which, in all the states of Italy except Naples, and the *Marcenne* of Rome and Tuscany, has been established from time immemorial, prevents the estate of any one proprietor from being very considerable. Three or four thousand a-year is reckoned a very great income. But though estates are not large, they are numerous; and it is to this cause that the multiplicity of the Italian cities is to be ascribed; for the proprietors universally live in towns. Their estates are every where let to the peasantry, on condition of paying half the produce to the landlord; and this produce is disposed of by the proprietors, as the consignments of a West Indian estate are by an English planter. (Chateaubvieux, 344. Young, II.) The lower stories of the palaces are filled with vast warehouses of wine, oil, and grain, the produce of the estates; and hence has arisen the singular custom of each great house at Florence, and in some other places, having an aperture in the wall beside the door, through which any quantity of wine, however inconsiderable, is sold to the inhabitants. These proprietors, in consequence, do not consider their estates as capitals yielding fixed rents, but as a property, the income of which varies according to the seasons, and the state of the markets. Their sole employment is looking after their estates, which they visit occasionally, and with the tenantry of which they are generally on the best terms. (*Ibid.*) After harvest the steward visits the farm to make a division of the crop. The farmer engages to convey the landlord's share to the city, where, as already mentioned, it is deposited in the large magazines appropriated to that purpose in the palace.

The variable state of the markets renders it necessary for the landholders to live in the most economical manner, in order to avoid incurring debt in unfavourable seasons. So small is the quantity of capital in the country, that if a proprietor is obliged to borrow, he is ruined in a few years. (*Ibid.* 345.) They never engage in any profession or line of industry to better their condition. If they can make their income cover their expenditure it is all they desire; and it is absolutely necessary that they do not permit any excess in the latter. Hence has arisen that remarkable disposition to economy which characterizes the Italian nobles, and that limited expenditure which has such important effects on the other classes of society. Their palaces are often wretchedly furnished, and their domestic consumption very moderate. In one particular only do they manifest a disposition to extravagance, namely, in their equipages. Every proprietor, however limited his income, conceives it absolutely necessary that he should keep a carriage and a pair of horses, with which he parades on the *Corso* in the evening before going to the opera. Hence in every town, however small, there is a *Corso*, and hence that extraordinary display of carriages and servants, which strikes a

stranger so much at Florence and Milan, and seems so entirely disproportioned to the wealth of these cities in other respects. Italy.

The *second* class, or that of merchants, is very considerable. Great as was the commercial wealth and activity of the Republics in former times, hardly any trace of this prosperous state of things now remains. Ever since the subjugation of Italy by the Spaniards, its commercial and manufacturing industry has declined; the necessary consequence of the insecurity of property, and the ruinous monopolies with which the exchange of commodities was everywhere shackled. (Sismondi, XVI. 237.) The trade which the Italians now carry on consists chiefly of the local or home trade of the country itself. This home trade, however, is considerable, and by means of the advantages which the vicinity of the sea shore affords, it is carried on with great safety and facility. Their foreign trade consists chiefly in exchanging for colonial goods and manufactured articles, the fruits, wheat, rice, silk, wine, wool, oil, and cotton, of their own country. It has greatly increased since the opening of the intercourse with England. A large class of the Italian artisans are now constantly employed in manufacturing alabaster and marble ornaments for the English market; for the natural taste of the inhabitants, and their proximity to the finest models of ancient taste, has preserved for Italy her wonted superiority in the fine arts, amidst the wreck of every other species of industry. The bankers, in most Italian towns, have realized considerable fortunes, in consequence of the advantages which their capitals gave them during the revolutionary war. Universally, however, in Italy, the capitals which are acquired in commerce are, as soon as possible, invested in land. The whole ambition of the mercantile class is to arrive at the rank, and to participate in the public estimation of *Posidenti*. Hence a merchant, or banker, is satisfied with a moderate fortune, and stops short in the career of commercial enterprise, in order to extricate himself from a class to which a certain degree of contempt is attached; and when he becomes a landed proprietor, he generally educates his sons to idleness. Merchants.

The *third* class, or that of manufacturers, is generally in a poor and depressed state. The main cause is, the great poverty of the agricultural classes, and the small expenditure of the landed proprietors, who possess almost the whole wealth of the country. Manufacturers.

The *fourth*, or professional class, is very numerous in Italy. There is probably no country in Europe in which the number of lawyers is so great. Litigation, indeed, is the favourite amusement of the higher orders; and the entire absence of every other employment, or any political interest, makes them enter into it with a degree of ardour which, to a foreigner, appears very surprising. The multitude of lawsuits is principally to be ascribed to the minute subdivision of landed property, and to the variety of questions constantly occurring concerning those canals to which so much of the fertility of the country is owing. (Chateaubvieux, 354.) Profession.

The clergy have been greatly reduced, both in point of number and opulence, by the events which

Italy. followed the French Revolution. The convents were everywhere suppressed by authority of the French government. (Chateaubvieux, 353.) Many of them, however, have since been restored to their possessions, but the greater part is still in the hands of lay proprietors. These new proprietors are chiefly lawyers, bankers, and tradesmen. (*Ibid.* 347.) The peasantry and agriculture of the country have gained hardly any thing by the change. The tenantry remain the same; their condition is unaltered; they only pay their rents to new masters. The old ecclesiastical proprietors let all their lands at half produce to their tenantry, like the other landholders, and they were more indulgent masters than those who have succeeded in their place. Hence it is a general observation throughout the country, that agriculture has gained nothing by the suppression of the monasteries. (*Ibid.*)

The clergy derive their income generally from foundations in land. In the Milanese, Piedmont, and the Venetian States, the tithe is so light that no complaints on the subject are heard: it usually varies from one-twentieth to one-fiftieth of the produce, and this extends only to particular lands. (Young, II. 271-2.) The suppression of the Jesuits in Tuscany was, by Leopold, converted into the means of relieving the cultivators of that Duchy from every species of tithe; the funds belonging to their order being formed into a fund for the gradual abolition of this burden. As the subsisting incumbents died, tithes were abolished in the parish, and the successor was paid out of this fund, or by a salary raised by an addition to the land-tax. At present, the patrimony of almost all the parishes in Tuscany consists in lands set apart for them. Of these the rector is the administrator, and he is bound by an oath, at entering into his office, to maintain them in good order, and, if possible, increase their produce. (Paoletti, 50.) In the Ecclesiastical and Neapolitan States, the numbers of the clergy were formerly very great. It was estimated that the ecclesiastics in the latter state amounted to 200,000 persons, who were proprietors of half the lands of the kingdom. Great part of these, however, have been confiscated during the Revolutionary wars; but what is the amount of the possessions which still belong to the church, cannot, with any accuracy, be stated.

It is computed, that, in the time of Bonaparte, 300,000 soldiers were raised at one period out of the Italian States; of which 80,000 were from the kingdom of Naples: 80,000 from the kingdom of Italy; and 140,000 from that part of Italy which was incorporated with the French empire. (Chateaubvieux, 352.) The amount of the military class is now greatly reduced.

Class of
Cultivators.

The last class, that of the cultivators, is by far the most numerous, and that which contributes the most to the wealth of the community. It is in its rural economy that we find the source, both of its great population, and of what remains of prosperity in Italy.

Manufac-
tures and
Commerce.

To this sketch of the different classes into which the population of Italy is divided, we shall subjoin a few remarks, illustrative of the history and present

state of her manufactures and commerce. Her agriculture will be treated of at some length in the following chapter.

Italy.

The main source of the wealth of Florence during the Republic was its woollen manufacture, which maintained above 30,000 souls. (Viliani, Chap. XI. sect. 93.) At a single fair woollen goods to the amount of 12,000,000 of crowns were sold; and 1s. a-week on the wages of the woollen manufacturers alone built the superb pile of the Cathedral. (Young, II. 280.) The woollen and silk manufacturers at Florence are still of some consideration; and a considerable number of artisans live by making vases, statues, and other models of the fine arts, most of which are purchased by English travellers. At Venice, the chief manufactures are silk, velvets, glass, and beads; the exportation of which, thirty years ago, hardly employed 200 bottoms, the poor remains of 3300, which at one period were maintained in the service of the Republic. Its commerce is now almost annihilated, in consequence of the systematic oppression of the Austrian government. In the Veronese, it is computed they make 100,000 ounces of silk annually. (Young, II. 278.) The manufactures of Milan, and the cities under its rule, at one period were considerable. In 1123, there was sent to Venice alone, from the Milanese States, cloth to the amount of 900,000 ducats. (Guilini, XII. 362.) At present this manufacture is very much decayed, though it still maintains a considerable number of hands. It is computed that the value of the silk produced in the Milanese is not less than 900,000 livres, or L.300,000 annually, nineteen-twentieths of which is exported. (Veri, I. 236.) Considerable manufactures of mosaic, china, and other ornaments, are to be found at Milan. Bergamo had a woollen manufacture of great antiquity, which is not yet entirely decayed; and its export of silk sometimes amounts to L.300,000 a-year. It has a manufactory of iron and steel, as well as Brescia; but both are of little estimation, and beyond comparison inferior to the English. (Young, II. 278.) On the whole, so inconsiderable are the manufactures of Lombardy, that nine-tenths of its exports now consist of the rude produce of the soil. In the ecclesiastical states, a considerable manufacture of mosaics, cameos, necklaces, and other ornaments, is carried on, especially at Rome; and Bologna employs 7000 or 8000 persons in the working of crapes and gauzes, which are very beautiful; but, in other respects, the national fabrics are not worth noticing. Piedmont exports annually unwrought silk to the amount of 17,000,000 livres, or L.748,000 Sterling, and about L.30,000 worth of damasks; the remainder of its exports consist of agricultural produce. The velvets and damasks of Genoa still preserve their ancient reputation, though the sale for them is greatly diminished; and rich silk stuffs are manufactured to a considerable extent at Lucca, and the adjoining towns. In the Neapolitan territory, manufactures are few, and of small importance. Cotton is manufactured in the southern provinces of Sorrento and Otranto. At Nardo and Gallatona are made coverlets which are exported to all parts of the world. The porcelain of Naples

Italy. may vie with any in Europe in elegance of form and beauty of design; and at Teramo, in Abruzzo, there is a considerable manufactory of pottery, which is sent into Germany by the way of Trieste. Tarento and Francavilla produce a sort of muslins greatly inferior, indeed, to those of England, but of some consideration in that country. Upon the whole, silks and velvets are the staple manufacture of Italy, and in the various states of preparation employ more hands than all its other manufactures put together.

There is one species of manufacture which, though inconsiderable in point of value, is of infinite importance to a large proportion of the Tuscan population, that of straw bonnets, which is carried on universally by the cottagers' daughters in the vale of the Arno, and is one principal cause of the well-being of the peasantry in that delightful region. A good worker can earn from thirty to forty sous a-day. It brings an annual return of 3,000,000 francs, or £.132,000 Sterling, and this is entirely shared amongst the young women by whom it is carried on.

CHAP. II.

Agriculture.—In Lombardy.—In Tuscany.—In the Campagna of Rome.—In the Campagna of Naples.—State of the Peasantry in these different Districts.

The mode of cultivation pursued in the different provinces of Italy is as different as can well be imagined in a country whose climate is nearly the same. This difference arises from the entire difference of the soil, and natural productions in the mountainous, from what obtains in the level districts of the country.

Agriculture of Lombardy. The great agricultural district of Italy is the plain of Lombardy and Piedmont. This magnificent plain is composed every where of a rich and deep loam. There are no gravel hills except near the Alps. The high mountains which overlook the plain pour down an immense number of streams, which are collected in canals, and conveyed in so many various directions, that there is scarcely any farm or meadow which has not the benefit of irrigation. This immense system of irrigation was completed at different times during the twelfth and thirteenth centuries, by the wealth and spirit of the commercial cities which filled the plain of Lombardy. The Naviglio Grande, which brings the water of the Tessino to the Milanese territory, was begun long before the date of any authentic records; but it was brought to Milan from Abbiate Grasso in 1177, and made navigable in 1271. (*Nuovo Raccolta dell'Acque*, VII. 97.) The canal of Muzza was executed in 1220, and brings the waters of the Adda to Marignano, and irrigates the district of Lodi. (Verri, *Hist. de Milan*, I. 240.) The Canal of Treviglio, which carries the water of the Brenta to the territory of Treviglio, was made in 1303; and, in 1460, the Great Canal of Martisano was begun, still the admiration of engineers, for the costly aqueducts which carry it across the rivers in its course. This system of irrigation was completed in 1497, by Leonardo da Vinci, who united the Naviglio Grande to

Italy. the Martisan; and both canals are so managed as to be emptied once a-year, for cleaning and repairs; the flood-gates being so nicely adapted, that all the superfluous waters which descend in torrents from the mountains are let off with perfect security. In 1296, a law was passed which gave every one the power of carrying water across the public highways, provided he erected stone-bridges; and since that time the system of irrigation has been gradually brought to such perfection, by means of little canals, branching off from the great ones, that there is now hardly a field to the eastward of the Tessino which is not amply provided with water.

Water is sold with as much accuracy as wine, at so much the hour, half-hour, or quarter. The usual price of an hour *per* week is 1500 livres. (Young, II. 168.) He who discovers a spring in his ground has the property of it, and may conduct it where he pleases, upon paying surface damages. These damages are all fixed by law. (Verri, 239.) Hence every new spring that is discovered becomes the head of a little canal; and the activity shown in economizing the water so produced is truly admirable. In the Milanese, a stream twenty-two inches broad and two deep, and running from the 24th March to September 4th, will sell for 1000 livres. (Young, II. 177.)

Nor is it surprising that these great efforts are made for the diffusion of water over this plain. Such is the effect of irrigation, that land which, without it, will only yield six livres an acre, is raised, by the application of water, to twenty livres. Grass fields, with an adequate supply of water, are mowed four or five times a-year. (*Ibid.*) The water is conveyed in little rills, planted on each side by willows, allowed to grow only to a certain height; in many places vines cluster up these willows, and their branches, spreading from tree to tree, are trained in pendent festoons. The inclosures are generally small, and the fields divided from one another, not by hedges, but rows of mulberries, poplars, and oaks. Such is the luxuriance of these woods, that the country, when seen from an eminence, or at a little distance, seems a continued forest; and this without any intermission, from Turin to Venice. (Chateaucieux, 15.)

The peasantry are everywhere *Metayers*; that is, half the stock requisite for cultivating the farm is furnished by the landlord, and half by the tenant; the former pays the taxes and repairs the houses; and the produce is equally divided between them. Few of the cultivators are proprietors of the ground which they labour. Throughout all Lombardy the farm-houses are large and well built. They are always constructed of red brick, and, uniting strength with neatness, preserve, notwithstanding the regularity and plainness of their form, a rustic character. The offices consist of a court of four equal sides, in the centre of one of which rises a square building of two stories. In the lower storey of this building the farmer lives; the upper forms his granary. The stables for oxen and cows lie on each side of the farmer's house, and complete one side of the square. On each of the other three sides of the court is a portico, from twenty to twenty-four feet wide, the roof of which is supported from with-

Italy. in by a range of columns, at the same distance from each other as from the wall. Half of the court is paved, and the other half is an area for threshing out the corn, and is composed of clay. All the fodder, straw, and implements about the farm are placed under the porticos. The manure is collected on the outside; and the exterior walls of the whole edifice are covered by vines. The neatness, cleanliness, and even elegance, of a Lombard farm-steading, is such as can hardly be imagined by those who have not visited that country.

The meadow part of the farm is let for a money rent, and this is often forty francs. The produce of the remainder of the farm is equally divided, as already observed, between the landlord and tenant. The labour is principally done by oxen, in most parts of the country. Generally speaking, the farms are small; from ten to fifty acres. (Chateaufvieux, 17.) In the Milanese they are larger, and in some places extend to 700 or 800 acres. Some of the farmers there are possessed of large capitals; from 50,000 to 100,000 francs, and feed 100 cows. (Young, II. 154.) The farms in the vicinity of Padua are small; and the ruinous system of middlemen prevails there and in the Bolognese territory.

The rotation usually followed in Piedmont is, 1. Maize, with hemp or French beans. 2. Wheat. 3. Clover. 4. Wheat. The remarkable recurrence of the grain crops is the consequence of the abundance of manure procured by mowing the grass lands three or four times a-year; the whole manure of which is laid on the arable land. The maize is considered as a preparatory crop. It is planted in drills, and hoed and earthed up like our potatoes, and the land kept perfectly clean. It is extremely productive, and constitutes the principal food of the peasantry over the whole of Lombardy. A number of French beans or hemp are mixed with the maize. The clover is sown in spring with the wheat. It is cut in autumn after the wheat is down. In the spring following it is cut again, and ploughed down, after which the land is ploughed three times as summer fallow. Wheat is sown again in autumn, which closes the rotation. Thus in the course of four years are three crops for the use of man, one fallow, and two crops for cattle. To these must be added the crop of hemp, which is often considerable; that of silk, wine, vegetables, and fruit, besides the ample produce of the meadow land. A farm of sixty acres, under this management, feeds a family of eight or nine persons, maintains twenty-two head of cattle, of which two oxen, a cow, and two pigs, are fattened every year. The value of its silk amounts at least to 25 louis d'ors; it makes enough of wine for the use of its inhabitants, and nearly the whole crops of wheat, and all the produce of the dairy, is carried to market. (Chateaufvieux, 30.)

The soil of the plain of Lombardy becomes richer as you move to the eastward; and in the Lodosan and Parmesan are found those admirable pastures which produce cheese celebrated over all the world. Every thing connected with the rural economy of this garden of Italy is interesting. Some of the farms are large, consisting of several hundred acres, and feeding above 100 cows; and so great is the

Italy. advantage of making the milk from a large dairy, that, when the farms are small, the farmers club together, to make their milk in common. (Young, II. 154.) Twice a day the milk of fifty or sixty cows, belonging to a society, is sent to the principal house, where the dairyman keeps an account of each person's proportion. The cattle in this district are the Hungarian breed, and of unrivalled excellence; the defects in that race being completely extirpated, by a cross with the Swiss, for which purpose 2000 cows have for time immemorial annually passed the St Gothard. The cattle are always fed in the house, upon mown grass, a method by which great economy, both in point of fodder and manure, is effected. The manure here is all applied to the meadows, and after twelve or fifteen years, they are broken up, and yield a rotation of, 1. Hemp, followed by vegetables; 2. Oats; 3. Wheat and Vegetables; 4. Maize; 5. Wheat. In these districts, the major part of every farm consists of meadows.

The rotation in the arable districts of this tract of Lombardy is as follows:

1st Year, wheat, after it maize and hemp—manured.

2d — Wheat.

3d — Winter beans.

4th — Wheat manured.

5th — Clover ploughed in, after once mowing.

6th — Wheat.

In the neighbourhood of Parma, tobacco is cultivated, and it comes instead of maize the first year.

This sketch may give a general idea of the husbandry of Lombardy; a country in which a more admirably system of culture is now pursued than any where else in Europe. In many places it is, of course, very different from what has been above described, and, in particular, rice crops are very frequent in the neighbourhood of Pavia, and thence eastward along the course of the Po. The rotation followed in the rice grounds is, 1. Rice; 2. Rice; 3. Rice; 4. Fallow and dung; 5. Wheat and clover; 6. Clover; 7. Clover; 8. Clover; 9. Flax and millet the same year, and then rice again as before. So great is the produce of this husbandry, that, on the rice grounds, 160 francs an acre is a common rent. In the Milanese also, two crops of corn are commonly gained in one year by sowing maize in July, after wheat, and wheat and millet, or rye, almost always are reaped in the same year. (Young, I. 203; Chateaufvieux, 278.)

The second agricultural district is that of Tus-Agriculture cany, in which the mountainous nature of the soil of Tuscany. has rendered a totally different system of cultivation requisite. Nothing can be imagined more sterile in itself, or more adverse to any agricultural improvement, than the aspect of nature in the Appenines. Their sides present a series of broken rocks, barren slopes, or arid cliffs. The roots of the bushes, laid bare by the autumnal rains, are, by degrees, dried up by the heat of the sun. They perish, and leave nothing behind them but a few odoriferous shrubs dispersed on the rocks, to cover the wreck. The narrow ravines between them present, in summer, only the dry beds of torrents, in which fallen trees, rocks, and gravel, are accumu-

Italy. lated by the violence of the winter rains. This *debris* is brought down by the torrents into the wider valleys, and whole tracts of country are desolated by a sterile mass of stone and gravel. Thus the mountains and the valleys at their feet seem equally incapable of culture; but the industry of the Italians has overcome these obstacles, and converted mountains, to appearance the most sterile that imagination could conceive, into a succession of gardens, in which every thing that is most delightful, as well as useful, is assembled.

This astonishing metamorphosis has been effected by the introduction of the *terrace system of culture*, an improvement which seems to have been unknown to the ancient Romans, and to have been spread in Europe with the return of the Crusaders, in the twelfth and thirteenth centuries. (Chateaufieux, 200.) Nothing could oppose the destructive force of the torrents, but altering the surface of the hills, and thereby breaking the course of the waters. This was an immense work, for it required the whole soil to be displaced, and built up by means of artificial walls, into successive terraces; and this, in many places, could be effected only by breaking solid rocks, and bringing a new soil from distant places.

The artificial land, so dearly purchased, is designed for the cultivation of fruits and vegetables. The terraces are always covered with fruit-trees placed in a reflected sun. Amidst the reverberations of so many walls, the fruit is most abundant and superior in its kind. No room is lost in these limited situations,—the vine extends its branches along the walls; a hedge formed of the same vine branches surrounds each terrace, and covers it with verdure. In the corners formed by the meeting of the supporting walls, fig-trees are planted to vegetate under their protection. The owner takes advantage of every vacant space left between the olive-trees to raise melons and vegetables; so that he obtains, on a very limited extent, olives, grapes, pomegranates, and melons. So great is the produce of this culture, that, under good management, half the crop of seven acres is sufficient for a family of five persons; being little more than the produce of three-fourths of an acre to each soul. This little space is often divided into more than twenty terraces. (*Ibid.* 302.)

A great part of the mountainous part of Italy has adopted this admirable culture; and this accounts for the great population which every where inhabit the Italian mountains, and explains the singular fact that, in scenes where nothing but continued foliage meets the eye, the traveller finds, on a nearer approach, villages and hamlets, and all the signs of a numerous peasantry.

Continued vigilance is requisite to maintain these works. If the attention of the husbandman is intermitted for any considerable time, the violence of the rains destroy what it had cost so much labour to create. Storms and torrents wash down the soil, and the terraces are broken through or overwhelmed by the rubbish, which is brought down from the higher parts of the mountain. Every thing returns rapidly to its former state; the vigour of southern vegetation covers the ruins of human industry; and

there soon remain only shapeless vestiges covered by briers. (*Ibid.* 303.) Italy.

In the valley of the Arno, the farms are extremely small; generally from three to ten acres. The peasants' houses are concealed from the eye of the passenger, by the olives which clothe the lower parts of the mountains, and by the luxuriant chesnut forests which adorn their higher ascents. They are generally, however, not more than 100 paces from each other, and are built of brick in the most elegant manner. For the most part they consist only of one storey, with a single door, and two windows in front. On the wall which surrounds it are often placed vases of antique forms, in which flowers, aloes, and orange trees, are growing. The houses are completely covered with vines, so that, during the summer, it is difficult to distinguish them from arbours. The land belonging to the farm lies round the houses, and is divided into fields by small canals, or rows of trees, some of which are mulberries, but the greatest part poplars. The poplars are pollarded, and each tree supports a vine, the branches of which are twined round in various directions, in such a manner, as to give the whole somewhat the form of the antique Tuscan vases. These divisions of the land are oblong squares, large enough to be cultivated by means of oxen, which here, as elsewhere, are employed in the works of agriculture. (Sismondi, *Agric. de Tosc.*; Chateaufieux, 76.) A pair is kept jointly by ten or twelve farmers, who employ them successively in the cultivation of their farm. They are of the finest Hungarian breed, and extremely docile. Every considerable farm maintains one horse, and a small painted cart, which serves for all the purposes of draught, and to carry the family to church. (Chateaufieux, 77.) The farmers have, in general, no other stock but heifers, which they buy at three, and keep till they are eighteen months old. There is hardly any meadow land, or artificial grass. The cattle are fed almost exclusively on the leaves of trees, the refuse of vegetables, and a little wild clover.

The rotation of crops is not uniformly the same; but it is very generally as follows:

1st Year, Maize and French beans, or other vegetables.

2d — Wheat.

3d — Winter beans.

4th — Wheat.

5th — Clover; sown after wheat in the spring, and followed by sorgho, which is a larger variety of parsnip. (*Ibid.* 78.) The land is manured only once in five years; nevertheless, such is the richness of the alluvial soil in the plain of the Arno, that the crops are all tolerably good.

The system of *irrigation* in this valley is a most extraordinary monument of human industry. Placed between two ridges of mountains, one of them very elevated, it was periodically devastated by numerous torrents, which were precipitated from the mountains, charged with stones and rubbish. To control these destructive inundations, means were contrived to confine the course of the torrents within strong walls, which serve at the same time

Italy. for the formation of a great number of canals. At regular distances, openings are formed below the mean level of the stream, that the water may run out laterally, overflow the land, and remain on it long enough to deposit the mud with which it is charged. A great many canals, by successive outlets of the water, divide the principal current, and check its rapidity. These canals are infinitely subdivided, and to such a degree, that there is not a single square of land which is not surrounded by them. They are all lined with walls, built with square bricks; the scarcity of water rendering the most vigilant economy of it necessary. A number of small bridges connect the multitude of little islands, into which these canals subdivide the country. These works are still kept in good repair; but the whole wealth of Tuscany could not now furnish the sums requisite for their construction. That was done by Florence in the thirteenth and fourteenth centuries, in the days of her Republican freedom. (*Ibid*, 80, 85.)

This mode of cultivation is followed all over the valley of the Arno, and on the lower ranges of hills which compose the chain of the Appenines. In the higher regions, the severity of the climate renders a different mode of proceeding necessary. The mountain pastures, at the summit of the Appenines, feed numerous flocks, which migrate in winter into the Maremma of Sienna, and the Campagna of Rome. The chesnut forests, with which the country abounds, furnish the peasantry with most of their subsistence; but incessant industry extracts a scanty crop of corn from the better parts of the soil. Land is everywhere much subdivided, and the cultivators are generally, as in the Alps, proprietors of the lands which they cultivate. (Young, II. 157, 152; Sismondi, *Agric. de Tosc.*) The case is very different in the plains and lower regions. A large proportion of the people derive their subsistence from migrating in summer, to cut down the harvests of Tuscany, Lombardy, and the Campagna of Rome; and with the money thus acquired they return annually, or after the lapse of years, to their native hills, where they become proprietors, and, by strict economy, contrive to maintain themselves for the remainder of their lives. (Sismondi, *Agric. de Tosc.*) Almost all the mountain pastures are let from year to year, to the shepherds of the Maremma, who bring their flocks hither in the summer season. The rent they pay for the season is a piastre for a horse, five sous for a sheep, and three for a goat. These shepherds limit themselves to one species of animal. Some rear horses, others sheep, others goats. They have no fixed residence, but live in sheds in the Appenines in summer, and in the Maremma in winter. (Chateauvieux, 58, 61.) The introduction of the potatoe would be a signal advantage to the inhabitants of these mountainous districts.

Almost universally in Tuscany land is let to the peasantry at half produce. The proprietor pays all taxes, except the capitation tax, and generally furnishes the live stock, and repairs the houses. Leases are not usual; but the peasantry lose nothing by that circumstance. The right to the farm generally descends from father to son, the landlords hardly ever

removing them. (Chateauvieux, 329.) The landlord is obliged to aid them in every season of distress;—a bad season often reducing them to the utmost misery. They never quit their mode of life, and have no means of rising in society.

The third agricultural division of Italy is the Agriculture of the Maremma, or the plains on the sea shore in Tuscany, and the Roman states, where the prevalence of the malaria renders it impossible to live permanently. This region is everywhere divided into great estates, and let in large farms. The Maremma of Rome, 40 leagues in length, and from 10 to 15 in breadth, and which feeds annually 67,000 horned cattle, is cultivated by only 80 farmers. These farmers live in Rome or Sienna; for the unhealthiness of the atmosphere precludes the possibility of their dwelling on the lands they cultivate. Each farm has on it only a single house, which rises in the midst of desolation. No garden, or orchards, or meadows, announce the vicinity of a human habitation. It stands alone in the midst of a vast solitude, with the cattle pasturing up to the walls of the dwelling.

The whole wealth of these great farms consists in their cattle. The farm servants are comparatively few, and they are constantly on horseback. Armed with a gun and a lance, the shepherds, as in the wilds of Tartary, are constantly in the open air tending the herds committed to their care. They receive no fixed wages, but are paid in cattle, which graze with the herds of their masters. The mildness of the climate permits the grass to grow during all the winter, and so the flocks are maintained there in that season. In summer, as the excessive heat renders the pastures parched and scanty, the flocks are sent to the highest ridges of the Appenines in quest of cool air and fresh herbage. The oxen, however, and cows of the Hungarian breed, are able both to bear the heat of summer, and to find food during its continuance in the Maremma. They remain, therefore, during all the year; and the shepherds who tend them continue exposed to the pestilential air during the autumnal months. The woods are stocked with swine, and the marshes with buffaloes. So great is the quantity of the live-stock on these immense farms, that on one visited by Mr Chateauvieux were cattle to the value of L.16,000 Sterling; and the farmer had two other farms on which the stocking was of equal value. (Chateauvieux, 157.)

These farms, however, are not exclusively devoted to pasture. The most favourable situations for wheaten crops are selected, and the sheep are folded there during the winter, in order to enrich the soil. In spring the oxen which range at large on the pastures are yoked in the plough by labourers hired at Rome for the purpose. The shepherds, who attend the cattle, are incapable of any such labour. The inhabitants of the cities bordering on the Maremma, and of the mountains, do the whole agricultural labour of the farm. These labourers get 40 sous a-day, and are furnished with bread from Rome by their employers. As many workmen are hired as there are oxen to plough with, in order that the work may be done as soon as possible. A farmer, in the Campagna of Rome, often yokes 100 ploughs at once. When the work is done, the labourers return to

Italy. the cities, and the oxen are dismissed to their pastures.

This first ploughing is only for the purpose of breaking the earth, and exposing the roots of the weeds to the sun. In a month the land is again ploughed, and the roots burned. These two ploughings are followed by two others at equal intervals in a cross direction to the first; so that, by the middle of September, the earth has been broken up four different times. The seed is then sown, and covered in by a slight ploughing. The harvest takes place the following summer, after which the land is left to rest for many years.

The farmer pays a money rent, which is estimated only for the arable part of the farm. He has a lease for years, and pays 18 francs the French acre, which is just equal to the Scotch. The land which is not susceptible of tillage is not estimated in the rent, although from it the farmer often makes his greatest profit, as the woods and marshes feed the horned cattle, pigs, and buffaloes.

A farm, which Mr Chateauvieux visited, consisted of 6000 acres of arable land, with an equal portion not fit for the plough. For this he paid 22,000 piastres, which, reckoning the piastre at 4s. 2d., is L.4583, 6s. 4d. Sterling, being 15s. the acre for the arable ground. The portion of 6000 arable acres was divided into nine parts, one of which was annually under crop, one fallow, and seven in grass. The land which was not arable fed 700 cows, and 2000 pigs. About one-tenth of these, however, belonged to the shepherds, and constituted the pay they received. The farmer cleared annually about 5000 piastres, or L.1200, besides 5 per cent. on the capital vested in his flocks. From this it appears, that the Campagna of Rome, how desolate soever in appearance, is by no means entirely unproductive.

Great efforts were made by Pius VI., and after him by the French, for the draining of the Pontine marshes. His plan was to draw parallel drains at certain distances from each other, running from north to south, and falling into the sea, at Bocca di Fuime, near Terracino. At an angle of 45° with these, cross-drains were to be drawn also parallel to each other. Two only of these canals were finished by this Pontiff, at an immense expence of human life (Eustace, I.); but they drained a very considerable portion of the marshes; and their complete success convinced the French engineers whom Bonaparte employed, that this was the proper mode of proceeding. Under the skilful direction of M. Prony, the works were revived with great activity; but the overthrow of the empire of Bonaparte prevented any considerable progress being made. The portion drained is covered with a beautiful turf, and yields magnificent crops of wheat, maize, hemp, and legumes. Such is the richness of this virgin soil, that many fallows are necessary to clear off the weeds, which grow with extraordinary luxuriance. The inhabitants of Piperno and Sermonetto, and of all the villages situate on the declivity of the mountains, which bound the marshes on the eastern side, rent portions of this land, and cultivate it without changing their dwellings; for experience has shown, that the drained land is nearly as much subject to the

malaria as that which is still under water. (Chateauvieux, 173.) Italy.

In the *Terra di Lavoro*, or Campagna of Naples, Agriculture the extreme richness of the soil has given rise to a mode of culture different from any which has yet been described. The aspect of this great plain is, perhaps, the most striking in point of agricultural riches that exists in the world. The great heat of the sun renders it necessary that the grain should be shaded by trees; and, accordingly, the whole country is intersected by rows of elms or willows, which divide it into small portions of half or three quarters of an acre each. A vine is planted at the foot of every tree; and such is the luxuriance of vegetation, that it not only rises in a few years to the very summit, but extends its branches in a lateral direction, so as to admit of festoons being trained from one tree to another. These trees are not pollarded as in Tuscany and Lombardy, but allowed to grow to their full height, so that it is not unusual to see a vine clustering round the top of a poplar 60 or 80 feet high. Under their shade the soil produces annually a double crop, one of which is of wheat or maize. Melons are cultivated in great quantities, and with hardly any manure. Thickets of fig-trees, of peaches, and aloes, grow spontaneously on the borders of the fields. Groves of oranges clothe the slopes, and spread their charming perfumes over the adjoining country; while the rocky eminences are covered with vines, which produce fruits of the most delicious flavour.

This rich plain is cultivated entirely by poor Metayers, who have farms from three to seven acres each, which they hold from the proprietor, on condition of paying him two-thirds of the produce. The redundancy of the population has so depressed the condition of the labouring classes, as to reduce them to the necessity of giving this proportion of the produce to the landlord, in place of a half, as in the north of Italy. Ploughs are seldom used in cultivation; the whole is done by means of the spade. The soil being mixed with ashes is so easily worked, that even children assist in the digging. Melons are sown in spring, and, after their fruit is gathered, wheat is sown, which ripens in September, and when the stubble is dug in, beans or clover, which vegetate during the winter, and are cut twice or thrice for the use of the cows or buffaloes. Most of the cottagers have a few goats, and one or two cows, which are fed chiefly on the leaves of the trees. The richer class have a horse or ass to carry their produce to market.

The rotation generally pursued in this Campagna is as follows:

- 1st year, Maize, with manure.
- 2d — Wheat.
- 3d — Onions and legumes.
- 4th — Wheat, followed by beans or clover.
- 5th — Melons, followed by maize.

This course of husbandry yields seven crops in five years; of which four are leguminous and three of corn. Besides their regular crops, they have the produce of the vines and other fruits which grow on the same land, and the leaves of the trees for their cattle. A

Italy. family of five persons is here maintained on a *third* of the produce of five acres; being the produce of *one-third of an acre to each soul*. The population in the Campagna is nearly 5000 to the square league. No where in the world, except perhaps in India, is such richness of soil and density of population to be found. (Chateaubvieux, 215.)

It only remains, in order to conclude this sketch of Italian agriculture, to mention the cultivation of Cotton, which is carried on to a considerable extent in the southern provinces of Naples, especially in the vicinity of Otranto, and in the Abruzzo. But the district where it is conducted with the greatest success, is in that fine valley which lies between Pompeii and Salerno, on the road to Pestum. It is there introduced into the regular rotation of crops. The farmers of this district produced for export, in the year 1812, 60,000 bales of cotton. (*Ibid.* 223.)

The land intended for this crop is turned over with the spade in March, and the seeds are sown in lines at the distance of three feet. The plants in the lines are two feet asunder. No manure is required for the soil; it needs only to be kept quite clean, and for this purpose women are employed during the whole season in weeding. As soon as the flowering is over, the ends of the branches are nipt off, in order to direct all the sap to the fruit. The harvest, which is long and tedious, consists in collecting the capsules as they ripen. Nothing is then required but to clear the cotton by separating it from the seeds. This operation gives employment to the women and children.

The above described course of husbandry, pursued in the Terra di Lavoro, leaves no room for this crop; and yet none of the crops there raised can be dispensed with. The Metayer, therefore, begins with the cultivation of maize, for which the land is manured,—wheat follows it, and beans are planted the same year for a winter crop. The land on which they grow is prepared for the cotton seeds by the end of March in the spring following; after it is harvested wheat is again sown the same autumn, to which clover succeeds. Melons succeed the clover, and legumes, planted as soon as the melon crop is taken off, occupy the ground until the spring, and finish the course. The rotation, therefore, is as follows:

- 1st year, Maize, manured.
- 2d — Wheat, followed by beans.
- 3d — Cotton.
- 4th — Wheat, followed by clover.
- 5th — Melons, followed by legumes.

This system yields eight regular crops in five years; besides the grapes, fruit, and leaves, which the same land produces. (*Ibid.* 225.)

Such is the system of husbandry pursued in the best parts of the kingdom of Naples. In the Maremma of Pestum the same pastoral habits obtain as in those of Rome and Tuscany; and the terrace husbandry is to be seen in some part of the mountains of Abruzzo and Calabria. But, in general, the Appenines in Naples are cultivated with much less industry than in the Tuscan states, the natural consequence of the oppressions of the nobles, and the despotic nature of the government. (*Ibid.* 233.)

Italy. The land is very much divided, and belongs, in the higher regions, to the peasantry; but their entire want of skill and capital renders them incapable of availing themselves of the advantages which their delightful climate affords. The most favoured spots only are selected for grain and vegetables; the greater part of the mountains are left to the olive and sweet chesnuts, which here grow in the utmost luxuriance, and constitute the principal support of the people. They migrate in great numbers to the low country in the season of harvest, and carry back with them a small pittance for the winter months. Yet notwithstanding their poverty, the climate compensates many disadvantages. The little gardens, which their children manage, furnish fruits, which are esteemed luxuries among the rich in northern climates.

The condition of the peasantry all over Italy, General State of the Peasantry. with the exception of Tuscany, is indigent and miserable. They live, indeed, in the midst of natural beauty; their dwellings are adorned with fruits and flowers; and the traveller, on a cursory view, is apt to imagine that the inhabitants participate in the riches with which they are surrounded. But if he enters their dwellings the illusion is destroyed. He will find them crowded in old and uncomfortable houses, and living in a manner the most penurious. In Lombardy, the labouring classes are, in general, ill clad, without shoes or stockings, and destitute of every species of comfort. Inhabiting a country which abounds in wine, they rarely taste anything but water. "The division of land among the tenantry," says Mr Young, "leads them to grasp at the least prospect of maintenance for a family; and population goes on with unlimited force, in consequence of the ignorance, the little frugality, and the absence of all artificial wants among the people." In the districts of Padua, Modena, and Bologna, and even a great part of the Ecclesiastical States, the system of *middlemen* prevails, and the condition of the cultivators is uniformly worse than where they hold directly of the landlord.

The situation of the people in the Tuscan States is greatly superior to what obtains in other parts of Italy. The number and opulent appearance of the villages, the inns and handsome shops, all bespeak the greater comfort of the middling and lower orders; and remind the English traveller of the cheerful and prosperous aspect of his own country. Nor is the comfort of the people less conspicuous in their dress and dwellings. On ordinary occasions their dress is neat and substantial, and on Sundays and festivals, costly and handsome. This obtains, however, chiefly in the valley of the Arno, where, as already observed, the women add to the earnings of the family by their manufacture of straw hats. In the remoter districts of the country, the peasantry are in a more depressed condition; bread and liquorice form their ordinary food, and meat is tasted only on Sundays; and not unfrequently the Metayers are so poor, that the landlord is obliged to lend them corn for food, when the produce of the harvests has been unfavourable. (Young, II. 156; Chateaubvieux, 79.)

Every traveller observes that the condition of the people in the Roman States is worse than in the

Italy.

northern parts of Italy. But their situation is still more depressed in the kingdom of Naples,—in that country where the plains annually yield a double crop, and where the mountains spontaneously produce the finest and most luxuriant fruits.

The miserable condition of the Neapolitan peasantry is not surprising when the multiplied oppressions and exactions to which they are subjected are considered. The *barons* have the right of life and death within their jurisdiction. They have a legal claim to one-tenth of the produce that grows within their lordships, and the exclusive right of erecting an oven, an oil-press, an inn, a mill, and a butcher's shop, that is, of exercising all the necessary arts. (*De Sali's Travels*, 197.) These privileges are sold by them by auction to the highest bidder. Many lordships, in addition to this, have the right of levying road and bridge-money, though both are generally in the most dilapidated state. If the baron be an oppressive and unthinking master, or if he does not reside on his estate, and the management devolves on a steward, the condition of the vassal under these privileges is truly deplorable. It is with the utmost difficulty they are able to pay the charges made upon them; and any appeal against injustice is out of the question, as the baron is himself the judge, and his decision can be brought under review only by endless litigation and at vast expence. (*Ibid.* 202.)

The *manna*, a substance which exudes from the leaves of a certain species of ash, belongs everywhere to the King; and to gather it a certain number of labourers are furnished by the lord of the barony. During the season that the collection of the manna lasts, which is about a month, none of the labourers so employed are allowed to absent themselves even for a day, to look after their own scanty harvest. If the peasantry are detected burning or injuring any of the trees on which this royal substance grows, or if the smallest quantity of the juice is found in their houses, they are punished with the utmost severity. The taxes are all farmed, and the mode of collecting them adopted by the farmers of the revenue is in the highest degree oppressive.

CHAP. III.

Government.—Police.—Manners.—Customs.—Charitable Establishments.

In all the states of Italy, the sovereign is vested with absolute power. The judgments even of the courts of law are reversed and altered according to his pleasure. He cuts off the rights of succession by legitimating a bastard; and sets aside the provisions made for families by dispensing with the fetters imposed on the eldest son. The privileges of public bodies are not less at his mercy than the rights of individuals; he changes at will the customs and privileges of cities, and the subsisting prerogatives of the different orders of the state. As everything depends on the will of the prince, so every measure is carried into execution by his sole authority, and without the intervention of any public deliberation, or the consultation of any class of men. Any public

criticism on political subjects would be considered as a high offence, and instantly prohibited. Modern history even is in many places an interdicted subject. The newspapers are subjected to the most rigid censorship, and contain almost nothing under the head of Italy but frivolous details of fashionable life.

The freedom of individuals is abridged to an inconceivable degree by the oppressive power which is everywhere vested in the *police*. To those who have lived only in Britain, it is hardly possible to convey a conception of the authority which, in all the Italian States, is thus exercised over the movements of individuals. In the provinces subject to Austria, especially, they have established a system of *surveillance* which makes them acquainted with everything that is going forward in private families. No Austrian subject is allowed to leave the Austrian provinces, unless his passport is signed by the Director-General of the Police at Vienna; and no foreign traveller can enter the Austrian territories unless his passport is signed by the Austrian Ambassador at some foreign court. It may here be observed, however, that the police treat natives in a much more despotic manner than foreign travellers. To the honour of the government of Florence, it must be admitted, that the police throughout all its territories, like every other branch of the government, is much less oppressive than in the rest of Italy.

It is of the nature of despotic government, however, to fail in the attainment of its own objects: and while it professes to preserve the public safety better than any other, it is incapable of affording that strong restraint upon crime which springs from the co-operation of all classes in a free country. In the Roman and Neapolitan provinces, robbery and murder are so common, as to have rendered travelling in many districts highly dangerous. Robberies are committed by large bodies of ten or twenty persons. If no resistance is made, they are not, in general, guilty of acts of cruelty. It is a common practice with these bands to carry off some individual who is connected with wealthy relations, and having got him secured in their retreats, they intimate to his relations, that, unless he is redeemed within a limited time, they will put their captive to death. A particular spot is assigned, where the ransom is to be deposited; and, upon its being found there, the prisoner is conducted blindfold, in the night, to the high road, and there set at liberty. Instances frequently occur in which 4000 or 5000 crowns are given to redeem individuals from this perilous situation. The Alban Mount is a favourite haunt of these depredators. They made several attempts to carry off Lucien Bonaparte from his villa at Frascati, and actually, on one occasion, succeeded in seizing his secretary. The road from Terracino to Naples is guarded by picquets of soldiers, placed at the distance of a mile from each other; but, notwithstanding these precautions, travelling there cannot yet be considered as perfectly safe. Such is the weakness of the Roman government, that the Pope, under the able direction of Cardinal Gonsalvi, actually deemed it prudent to enter into a treaty with a leader of banditti, who surrendered himself on condition of being confined two years in the Castle

Italy. of St Angelo, on a pension of about eighteenpence a-day, at the expiration of which period he is to be set at liberty. When the writer of this article was in Rome (in 1819), this noted criminal, known to have committed many murders, and numberless acts of robbery, was living much at his ease, in that celebrated fortress.

In Italy the higher classes reside almost constantly in towns. During a few months in autumn, indeed, some of them resort from Milan to villas on the banks of the Lake of Como; from Florence to the baths of Lucca; from Naples to Castello Mare, on the adjacent shores; and the Malaria of Rome drives the whole of the wealthier classes to Tivoli, Frascati, or Albano, during the dangerous season of August and September. Many villas, in beautiful situations, are to be seen round the Italian lakes, on the hills which surround the valley of the Arno, and on the enchanting shores of the Bay of Naples. But these are occasional, not permanent residences. Nowhere is a *country house*, in the English sense of the word, to be seen. The idea of building and living on his estate, seems never to enter the mind of an Italian proprietor. Field-sports are wholly unknown in the north of Italy, as might well be expected among a people whose habits are formed entirely to a city life. What they call going to shoot at Genoa, is sitting down in a little *bosco*, or wood, composed of ten or twelve young trees, in the corner of a garden, where the sportsman fires at crows and magpies, as they fly past. In Naples, however, the love of shooting is very common, and is particularly fashionable at Court; but the mode in which it is practised, by collecting an immense number of wild animals, in some enclosed space, and firing at them as they issue from an outlet, accords but ill either with the feeling of *fair play* between the sportsman and his game which prevails in England, or with the active and energetic habits from which the love of it in this country has arisen.

It is one consequence of this almost entire oblivion of the country by the Italian landholders, that the noble youth are bred up in habits of indolence and inactivity, which, to an inhabitant of the north of Europe, seem altogether contemptible. They are seldom to be seen before dinner, but trifle away the forenoon, or occupy it in the pursuits of gallantry. The nobles dine in general alone; and invariably drive in the afternoon to the Cassino, or the Corso, where every lady is attended by her *cavaliere serviente*. The cavalcade proceeds to a fashionable confectioner's, where ices and lemonade are procured, and thence moves on to the opera. Here cards or conversation supply the amusement required by persons doomed daily to witness the same sort of performance. This style of manners prevails alike in the least as in the greatest towns; for, however inconsiderable the population of a city may be, it has its theatre and its Corso.

The universal disposition of the Italian proprietors to this mode of life, is the cause of the vast number of towns which are to be met with in every part of Italy, more especially in the plain of Lombardy; and of that polish of manners, which has descended so low in the scale of society. The coarseness which

in this country too frequently disgraces the middling classes, and tarnishes the sterling virtues they possess, is there in a great degree unknown. The continual presence of all the higher orders, and the constant display of their manners in the places of general resort, has given to the middling and lower classes a degree of elegance, and a taste for the enjoyments of cultivated life, to which there is nothing comparable in any other part of Europe. Intoxication is almost entirely unknown, or, when it does occur, is looked upon with the utmost abhorrence. The amusements of the lower orders in the cities consist of dancing, singing, conversation, walking, and frequenting the public theatres. Even the peasants in the country participate in those elegant amusements, which seem natural to this genial climate. An English traveller being benighted in the Appenines, near Carrara, two years ago (1819), not only met with a most hospitable reception from a small farmer, who refused to accept any remuneration, but was charmed the whole evening by his three daughters, who had recently completed their education at Leghorn, and sung in parts in the most beautiful manner. Every peasant, in the vale of the Arno, has a horse and small cart, which is used partly to convey the family to church, and partly to carry the daughters to the rustic balls, which, during the summer months, are frequent in Tuscany. (Chateauvieux, 76.) Generally speaking, the Italian peasantry are a kind, affectionate, and contented people, who, though poor, enjoy with thankfulness the bounties of nature, without repining at the humble lot which providence has assigned them.

The taste of the middling and lower orders for the fine arts, and their capacity of appreciating their excellencies, is very remarkable. The tradesmen in towns, the persons whom you meet with in public conveyances, discuss the merits of poetry, music, and architecture, with an enthusiasm and a discrimination, which is hardly to be found in the most polished circles on the north of the Alps. Even the peasantry display a taste in works of design, which no other country exemplifies. If a Virgin and Child are painted on the exterior of a cottage by the meanest artisan of the village, the work has a grace and air peculiar to Italian painting. Nor is the taste of the people less conspicuous in their dress and habitations. The farm-yards in Lombardy are surrounded with porticos and colonnades, composed, indeed, of the simplest materials, but chaste and elegant in their design; and some of the most striking features of Italian landscape consist of the picturesque forms in which the village churches and common country houses are built. It has long been matter of proverbial remark, that the Italians have an instinctive taste for music; and the proof is to be found not only in the nice discrimination of the beauties of the opera, which is displayed even by the lowest of the populace, but in the charming airs which are sung in every part of the country.

One remarkable peculiarity remains to be noticed, namely, the fondness which all ranks manifest for the exhibitions of *Improvvisatori* composers, and the singular talent for this species of exhibition which is frequently to be met with. In the streets of Venice,

Italy.

Italy. of Rome, and Naples, the attention of the traveller is often arrested by a group of persons who surround some wandering composer of this description; and it is difficult to say which is most worthy of astonishment, the ease of the language in which the tale is delivered, or the intense interest which is evinced by the audience. Nor is it only among the lower classes that this passion is prevalent. It exists equally in the highest and most cultivated ranks; and the talent which the performers display is such as can scarcely be credited by those who have not witnessed their exhibitions.

When the *Improvvisatore* is to make an exhibition, he demands a subject; and after six or eight minutes' thought begins his song, which often extends to five or six hundred verses, in which, not unfrequently, noble bursts of passion and poetical feeling captivate and astonish the audience. Many of these extempore composers voluntarily select the most difficult versification: sometimes the triple rhyme of Dante, sometimes the octavos of Tasso.

Nor is it only among the Italian men that this singular talent manifests itself. The most admirable Improvisatori of modern times have been found in the other sex. The celebrated Corilla, who was crowned at the Capitol, captivated all Italy by the brilliancy of her imagination, and the elegance of her manner; and suggested to the most distinguished female writer of modern times the original of her inimitable Corinne. La Faulistica of Florence, and La Bandittini of Bologna, have been celebrated in a lesser degree; the former for the melody of her versification, and the latter for the vast extent of the classical and historical information which she introduced into her poetry. The most remarkable Improvisatori of the present day is Madame Mazzei, a lady of high rank at Florence, who surpasses all her predecessors in the fertility of her imagination, the harmony of her style, and the perfect regularity of her versification. She does not sing, and has little power of recitation; but when she begins an improvisatory composition, her language and manner bear the marks of the highest poetical genius.

The dress of the peasantry is extremely various, and, in general, highly picturesque. In Naples, more especially, and in the mountainous part of the Neapolitan territory, the colours they wear are commonly scarlet and blue; and the warmth of the climate obliges the men to throw their coats over their shoulders in a manner peculiarly adapted for painting. When we see the brilliant and varied colours of the dress of both sexes in the Italian villages, and attend to the rapid and violent gesticulations into which the people throw themselves even in ordinary conversation, it is not difficult to perceive whence the Italian painters have drawn both the conception of drapery, and the extraordinary power of representing passion which characterizes their school.

The corruptions of religion in this country are universally known; but it is but justice to the Italian parochial clergy to say, that their lives are often spent in the most exemplary manner; and that, by a rigid adherence to the practice of virtue, they not only present a most salutary example to their flocks, but

Italy. counteract, in a great measure, the pernicious effects of some of the religious doctrines which they are obliged to inculcate. In the mountains, more especially, which surround the Italian lakes, or which shut in the delightful valley of the Arno, they live on the most cordial terms with their parishioners; and in the unnoticed discharge of their duty, present an example which may put many northern ecclesiastics to the blush for the opportunities of doing good they have neglected, and the great acquirements they have turned to no useful purpose.

In justice to the peasantry, it must also be observed, that they seem generally to be strongly impressed with their religious duties, and to join with sincerity in the exercise of devotion. To them, the Catholic religion is divested of most of its worst consequences; and the universal charity which it inculcates has had a material effect in softening and humanizing their manners.

In the great Christian virtue of *charity*, indeed, none of the Italians, of whatever rank or description, can be accused of being deficient. A population, which has nearly reached the utmost verge of subsistence, and the continued pressure of despotism, necessarily occasion a great deal of misery; and the same causes to which the misery is owing, have materially diminished the ability of the higher orders to relieve it. Yet, the provision which is made in most of the great towns, for the relief of distress, and of the poor, is such as to afford a splendid example of Christian beneficence. There are above sixty charitable foundations in Naples. Of these, seven are hospitals for the sick; thirty are receptacles for orphans, foundlings, and other destitute persons; five are banks for the occasional relief of such poor persons as stand in need of the loan of small sums of money, and the others are schools or confraternities. (Eustace, I. 499.) The income of these establishments is very considerable, and is derived principally from grants of land received from the piety of former times; but the expenditure is generally greater than the regular income. But the deficiency, however great, is abundantly supplied by donations, most of which come from unknown benefactors. (*Ibid.*)

All the other cities exhibit more or less the same amiable concern for human suffering. It is computed that the annual revenue of the charitable institutions of Milan amounts to L.87,000 a-year. (Young's *Travels*, II. 645.) In the great hospital, there are commonly from 2000 to 3000 patients; yet such is its revenue, that the directors are enabled annually to divide a large surplus of money among the other charities. The other charitable institutions of that great city are very numerous.

Without doubt, many of these charitable establishments are attended with pernicious consequences, and this has been very forcibly observed by an intelligent French writer (Lalande, Vol. V. 166), who ascribes to the great number of hospitals in Rome, and the facility with which soup and alms can be procured at the convents, much of the mendicity and idleness which prevail in that metropolis. Yet misdirected and pernicious as this charity may often be, it is impossible to refuse admiration to the truly Christian spirit from which it has arisen; and it

Italy
||
Jurispru-
dence.

is not to be forgotten, that this virtue is strongly and variously exemplified, even in the highest ranks. The society of the *Misericordia* at Florence includes 400 persons, among whom the principal nobility are to be found. Their duty is to attend the sick and bury the dead; and they permit no circumstance, however painful, to interfere with this duty. (Williams's *Travels*, I. 143.)

Much of all this is, without doubt, to be ascribed to the efforts of the clergy, who incessantly inculcate charity, as the most efficacious means of atoning for a life of wickedness. But it is not, perhaps, unreasonable to conclude, that despotism, by entirely depriving the rich of employment or any species of political interest, has had a material influence in directing towards charitable and benevolent objects, those warm feelings which the Italians possess in a greater degree than any other people of Europe, and which cannot be satisfied, at least in

advanced years, by the heartless gallantry of a fashionable life.

JURISPRUDENCE.

THE object and end of the science, which is distinguished by the name of Jurisprudence, is the protection of rights.

The end of
Jurispru-
dence, viz.
the Protec-
tion of
Rights.

The business of the present discourse is, therefore, to ascertain the means which are best calculated for the attainment of that end. What we desire to accomplish is,—the protection of rights: What we have to inquire is,—the means by which protection may be afforded.

Importance
of the In-
quiry, as
involving
Human
Happiness.

That rights have hitherto been very ill protected, even in the most enlightened countries, is matter of universal acknowledgment and complaint. That men are susceptible of happiness, only in proportion as rights are protected, is a proposition, which, taken generally, it is unnecessary to prove. The importance of the inquiry, therefore, is evident.

Confusion
in the vul-
gar uses of
the word
Right.

It is requisite, as a preliminary, to fix, with some precision, what we denote by the expression *rights*. There is much confusion in the use of this term. That disorderly mass, the Roman law, changes the meaning of the word in the two members into which it divides the subject, *Jura Personarum* and *Jura Rerum*. In the first of these phrases, the word *Jura* means a title to enjoy; in the second, it must of necessity mean something else, because things cannot enjoy. Lawyers, whose nature it is to trudge, one after another, in the track which has been made for them; and to whose eyes that which is, and that which ought to be, have, often, no mark of distinction, have translated the jargon into English, as well as into other modern languages.

This is not all the confusion which has been incurred in the use of the word *right*. It is sometimes employed in a very general way, to denote whatever ought to be; and in that sense is opposed to wrong. There are also persons, but these are philosophers, pushing on their abstractions, who go beyond the

sense in which it is made to denote generally whatever ought to be, and who make it stand for the foundation of whatever ought to be. These philosophers say, that there is a right and a wrong, original, fundamental; and that things ought to be, or ought not to be, according as they do, or do not, conform to that standard. If asked whence we derive a knowledge of this right and wrong in the abstract, which is the foundation and standard of what we call right and wrong in the concrete, they speak dogmatically, and convey no clear ideas.* In short, writers of this stamp give us to understand, that we must take this standard, like many other things which they have occasion for, upon their word. After all their explanations given, this, we find, is what alone we are required, or rather commanded, to trust to. The standard exists,—Why? Because they say it exists; and it is at our peril if we refuse to admit the assertion. They assume a right, like other despots, to inflict punishment, for contumacy, or contempt of court. To be sure, hard words are the only instrument of tyranny which they have it in their power to employ. They employ them, accordingly; and there is scarcely an epithet, calculated to denote a vicious state of the intellectual, or moral part, of the human mind, which they do not employ to excite an unfavourable opinion of those who refuse subscription to their articles of faith.

With right, however, in this acceptance, we have at present no farther concern than to distinguish it clearly from that sense in which the word is employed in the science of jurisprudence. To conceive more exactly the sense in which it is employed in that science, it is necessary to revert to what we established, in the article GOVERNMENT, with regard to the end or object of the social union, for to that,

Use of the
term Right,
in the
science of
Jurispru-
dence.

* See the writings of Kant and his followers, *passim*; see also Degerando, and others of his school, in various parts of their works.

Jurisprudence.

every thing which is done in subservience to the social union, must of course bear a reference.

In that article it appeared, that, as every man desires to have for himself as many good things as possible, and there is not a sufficiency of good things for all, the strong, if left to themselves, would take from the weak every thing, or at least as much as they pleased; that the weak, therefore, who are the greater number, have an interest in conspiring to protect themselves against the strong. It also appeared, that almost all the things, which man denominates good, are the fruit of human labour; and that the natural motive to labour is the enjoyment of its fruits.

That the object, then, of the social union, may be obtained; in other words, that the weak may not be deprived of their share of good things, it is necessary to fix, by some determination, what shall belong to each, and to make choice of certain marks by which the share of each may be distinguished. This is the origin of right. It is created by this sort of determination, which determination is either the act of the whole society, or of some part of the society which possesses the power of determining for the whole. Right, therefore, is factitious, and the creature of will. It exists, only because the society, or those who wield the powers of the society, will that it should exist; and before it was so willed, it had no existence.

It is easy to see what is the standard, in conformity with which the rights in question *ought* to be constituted; meaning by *ought*, that which perfect benevolence would desire. It is the greatest happiness of the greatest number. But whether rights are constituted, that is, whether the shares of good things are allotted to each, according to this standard, or not according to this standard, the allotment is still the act of the ruling power of the community; and the rights, about which the science of jurisprudence treats, have this alone for the cause of their existence.

The principal ideas involved in the Jurisprudential sense of the word Right. In this complicated term, it is obvious that there is involved, on the one hand, the idea of the person to whom a share is allotted, and, on the other hand, an idea of the things which are allotted. The one is the owner of the right, the person to whom it belongs; the other is the object of the right, namely, the person or thing over which the right gives certain powers.

All Objects of Rights are things desired; and desired as means to an end. All rights of course are to objects of human desire,—of nothing else need shares be allotted. All objects which men desire, are desired, either as the end, or as means. The pleasurable state of the mind is the end; consisting of the feelings of the mind. It would be absurd, however, to speak of giving a man a right to the feelings of his own mind. The objects of desire, therefore, which are the objects of right, are not the pleasurable feelings themselves, which are desired as the end, but the objects which are desired as the means to that end.

The Objects of Rights are twofold, viz. either Persons or Things. Objects of desire, as means to that end, may be divided into the class of persons and the class of things. Both may be the object of rights. In framing our language, therefore, we may say, that all rights are the rights of persons; but rights may be to either persons or things.

All that men desire, either with persons or things, is to render them subservient to the end, for which they are desired as means. They are so rendered by certain powers over them. All rights, then, when the term is closely investigated, are found to mean powers; powers with respect to persons, and powers with respect to things. What any one means when he says that a thing is his property, is, that he has legalised the power of using it in a certain way.

It is no part of the present inquiry to ascertain what rights *ought* to be constituted, or what rights perfect benevolence would choose to see constituted. That belongs to the question how government should be constituted; in other words, how the powers which are necessary for the general protection ought to be distributed, and the advantages of the union to be shared. At present our sole endeavour is to ascertain the most effectual means which the governing power of the state can employ for protecting the rights, whatever they are, which it has seen meet to create.

Rights, it must be remembered, always import obligations. This is a point of view, which, in the consideration of rights, has not, in general, attracted sufficient attention. If one man obtains a right to the services of another man, an obligation is, at the same time, laid upon that man to render those services. If a right is conferred upon one man to use and dispose of a horse, an obligation is laid upon other men to abstain from using him. It thus appears, that it is wholly impossible to create a right, without at the same time creating an obligation.

The consequences of this law of nature are in the highest degree important. Every right is a benefit; a command to a certain extent over the objects of desire. Every obligation is a burden; an interdiction from the objects of desire. The one is in itself a good; the other is in itself an evil. It would be desirable to increase the good as much as possible. But, by increasing the good, it necessarily happens that we increase the evil. And, if there be a certain point at which the evil begins to increase faster than the good, beyond that point all creation of rights is hostile to human welfare.

The end in view is a command over the objects of desire. If no rights are established, there is a general scramble, and every man seizes what he can. A man gets so much, and he is interdicted by the scramble from all the rest. If rights are established, he also gets so much, and is interdicted by his obligations from the rest. If what he obtains by his right exceeds what he would have obtained by the scramble, he is a gainer by the obligations which he sustains.

If it is proposed to create rights in favour of all the members of a community, the limits are strict. You cannot give all your advantages to every one; you must share them out. If you do not give equal rights to all, you can only give more than an equal share to some, by diminishing the share of others, of whom, while you diminish the rights, you increase the obligations. This is the course which bad governments pursue; they increase the rights of the few, and diminish the rights of the many, till, in the case of governments virtually despotic, it is all right on the one side, all obligation on the other.

Jurisprudence.

Rights, when closely investigated, mean Powers—Powers with respect to Persons, and Powers to Things.

Every Right imports a corresponding Obligation.

No Creation of Good, by Right, without the Creation of Evil.

Jurisprudence

It may be necessary to say a word, to prevent misconstruction of the term "equal rights." Rights may be truly considered as equal, if all the sorts of obligation under which a man lies with respect to other men, they are placed under with respect to him; if all the abstinences which he is obliged to practise with respect to their property, they are obliged to practise with respect to his; if all the rules by which he is bound not to interfere with their actions bind them equally not to interfere with his. It is evident, that inequality of fortune is not excluded by equality of rights. It is also evident, that, from equality of rights must always be excepted those who are entrusted with the powers of the community for the purposes of government. They have peculiar rights, and the rest of the community are under corresponding obligations. It is equally evident that those must be excepted who are not *sui juris*, as children in non-age, who must be under the guidance of others. Of two such classes of persons the relation to one another, that is, their reciprocal rights and obligations, need to be regulated by particular rules.

It is presumed that these illustrations will suffice to fix, in the minds of our readers, the exact meaning which is intended, in the present discourse, to be attached to the word *rights*. The sequel is to be occupied in discovering the means which are most proper to be employed for affording *protection* to those rights.

Meaning of the Word Protection, in the Jurisprudential Phrase, Protection of Rights

In the term *protection*, it is hardly necessary to give notice, that we do not here mean protection against foreign enemies; that protection which is to be yielded by employing armies against invaders. The protection, of which it is the business of jurisprudence to find out, and to describe the means, is that which is required by one member of the community against the other members. The members of the community, each of whom endeavours to have as much as possible of the objects of desire, will be disposed to take those objects one from another; to take them, either by force, or by fraud. The means of preservation are, therefore, to be found. Certain members of the community, as organs of government, are furnished with powers for that purpose. The question is, what powers are required; and in what manner are they to be employed?

In proceeding to present what may be called a sort of skeleton map of the ill-explored country of Jurisprudence, it is necessary to warn the peruser, that he must supply, by his own attention, what the limits of the work did not permit to be done for him. The several topics are rather indicated, than expounded. It is hoped they are indicated so clearly, that there will be no difficulty in spreading out the ideas in detail. It is necessary, however, that the reader should do this for himself. As the writer has not been able to dwell upon the several topics, though of the utmost importance, long enough to stamp the due impression of them upon the mind; unless the reader takes time to do this, by reflection on each topic, as it arrives, he will pass to the succeeding ones without due preparation, and the whole will be perused without interest and without profit.

VOL. V. PART I.

These men's rights may be effectually secured, it is obviously necessary, in the first place, that they should be capable of being accurately known. This seems to be so undeniable, that it would answer little purpose to enlarge in its illustration. It is, however, exceedingly necessary that the importance of this requisite should be clearly and adequately conceived. How can a man's rights be protected from encroachment, if what are his rights be uncertain or unknown? If the boundary by which his rights are distinguished is clear and conspicuous, it is in itself a protection. It warns off invaders; it serves to strike them with awe; for it directs the eyes and indignation of mankind immediately and certainly to the offender. Where the boundary, on the other hand, is obscure and uncertain, so far scope is allowed for encroachment and invasion. When the question, to which of two men an article of property belongs, comes for decision to the judge, the question is easy, if accurate marks are fixed, to point out and determine the rights of each. If no marks are attached, or such only as are obscure and variable, the decision must be arbitrary and uncertain. To that extent the benefit derived from the creation and existence of rights is diminished.

It is, therefore, demonstrable, and we may say demonstrated (the demonstration not being difficult), that, in the inquiry respecting the means of protecting rights, the *Definition of Rights* may be entered at the head of the list. Without this, as the groundwork, all other means are ineffectual. In proportion as rights can be ascertained, are the judicial functions, and judicial apparatus, capable of being employed to any beneficial purpose. In proportion to the facility with which they can be ascertained, is the extent of the benefit which the judicial functions are enabled to secure.

Such, then, is the first of the means necessary for the protection of rights. That they may receive the most perfect possible protection, they must be as accurately as possible defined.

In supposing that rights have need of protection, we suppose that there are acts by which rights are violated. With regard to those acts, the object is twofold; to redress the evil of the act when it has taken place; and to prevent the performance of such acts in future. To prevent the performance, two classes of means present themselves; to watch till the act is about to be committed, and then to interpose; or, to create motives which shall prevent the will to commit. It is but a small number of cases in which the first can be done; the latter is, therefore, the grand desideratum. From the view of these circumstances, we discover two other articles in the catalogue of means. Those acts by which rights are violated require to be made accurately known, in other words, to be defined; and the motives which are fitted to prevent them must be duly applied. Motives sufficient to that end can only be found in the painful class; and the act by which they are applied is denominated punishment. The definition, therefore, of offences, or of the acts by which rights are violated, and which it is expedient to punish, and the definition of the penalties by which they are

Jurisprudence

The first Requisite to the Protection of Rights is to make them capable of being known.

Definition of Rights, the first Instrument of Protection.

Definition of the Acts by which Rights are Violated, and the Application of Preventive Motives, another Instrument of Protection.

Jurisprudence.

opposed, are not less necessary than the definition of rights themselves. The reasons which demonstrate this necessity are so nearly the same with those which demonstrate the necessity of the definition of rights, that we deem it unnecessary to repeat them.

Civil and Penal Codes—What.

The definition of rights constitutes that part of law which has been generally denominated the *civil code*. The definition of offences and punishments constitutes that other part of law which has been generally denominated the criminal or *penal code*.

Code of Procedure—What.

When rights are distributed, and the acts by which they may be violated are forbidden, an agency is required, by which that distribution may be maintained, and the violators of it punished. That agency is denominated judicature. The powers, by which that agency is constituted, require to be accurately defined; and the mode in which the agency itself is to be carried on must be fixed and pointed out by clear and determinate rules. These rules and definitions prescribe the form and practice of the courts, or mode in which the judicial functions are performed; and constitute that branch of law which has been called the *code of procedure*.

Corpus Juris, or Body of Law—What.

These three codes, the civil code, the penal code, and code of procedure, form together the whole subject of jurisprudence. Of the three, it sufficiently appears, that the last exists only for the sake of the proceeding. Courts and their operations are provided that the provisions of the civil and penal codes may not be without their effect. It is to be considered, therefore, as subordinate, and merely instrumental, in respect to the other two. They form the main body of the law; this is an accessory to the main body, though an accessory of indispensable use. It would be of great advantage to affix characteristic names to distinguish from one another the main and accessory parts of law. Unexceptionable names, however, it is not easy to find. Mr Bentham, the great improver of this branch of knowledge, has called the civil and penal codes together, by the name of "substantive law," the code of procedure by that of "adjective law;" not, we may be satisfied, because he approved of these names, but because the language hardly afforded others to which equal objections would not apply. In the very sense in which either the term accessory, or the term adjective can be applied to the code of procedure, both may be applied to the penal code, as it respects the civil. The penal code exists purely for the sake of the civil; that the rights, which are ordained by the legislature, and marked out by the terms of the code, may be saved from infringement. The civil code is therefore the end and object of all the rest. The code of procedure, however, is auxiliary to each of the other two; the penal code to no more than one.

Having now explained the nature of the three codes which constitute the body of law necessary for the protection of rights, it remains that we illustrate, as much in detail as our limits will permit, what is required for the perfection of each.

What is required for the perfection of the Civil Code.

The grand object of the civil code is the definition of rights. Rights are sometimes more, sometimes less extensive. Thus the right of a man to a horse may solely extend to use him in riding from one stage to

another; or it may extend to the power of doing with him as he pleases. In like manner, the rights of a man with respect to a person may extend only to some momentary service, or they may go the length of slavery. Even slavery itself does not imply rights always equally extensive. In some cases, however, it implies rights as extensive over the slave as over the inferior animals.

Jurisprudence.

All rights, when the essence of them is spoken of, are powers; powers to an individual which the governing members of the community guarantee; powers more or less extensive, of making either a person or a thing subservient to the gratification of a desire. To be made to gratify the desire of an individual, is to be made to render him a *service*. And this term may, fortunately, be applied to both persons and things. A man receives a service from the field when it produces a crop, as well as from the servant and the horse who ploughed it. In one meaning of the word service, it implies only active service, or that rendered by the voluntary operations of sentient beings. In the present case, however, it is employed to denote both active and passive services. It is evident, that in every case in which a being inanimate is rendered subservient to the gratification of a desire, the service is, properly speaking, a passive service. It is also evident, that even animate beings are rendered subservient to the gratification of desires in a way which may equally be called passive.

It is necessary to request attention to the explanation which is here given of the meaning in which the term *service* is to be employed: as both the English and the Roman lawyers use it in a very restricted sense. Here it is employed to denote the whole of that ministration to the gratification of our desires, which we are entitled, in consequence of rights, to derive either from persons or from things. Rights are powers, and the powers are means for the obtaining of services. We have now, therefore, a language, by the help of which we may speak with tolerable clearness.

Our object is to define rights, and rights are powers. But these powers can be defined, only by a reference to the services which they are the means of obtaining.

The first thing, therefore, to be done for the definition of rights is, to make out a list of all the kinds of services, which the legislature permits an individual to derive, first, from persons, and secondly, from things. This would not be a matter of very great difficulty. It would be right to begin with the most simple cases, and go on to the more complex. Thus, in the services derivable from a person, some are limited to a single species of act, and that within a limited time, and at a particular place. Others are services, consisting of various acts, limited or not limited in space and time. And lastly, are the whole services which a man is capable of rendering; without limitation as to either space or time. Considerable pains would be necessary to make the list complete; and not only considerable pains, but considerable logic would be necessary, to classify the services, in other words, make them up into lots, the most convenient for the purpose in

Operations preliminary to the Definition of Rights.

Jurisprudence.

question; and to fix the extent of each by an exact definition. It is obvious, that as soon as all the possible gradations, in the services which one human being can render to another, are exhibited by such enumeration and assortment, it is easy for the legislature to point out exactly whatever portion of these services it is its will to give any individual a right to.

The same considerations apply to the class of things. In being made subservient to the gratification of our desires, they also render services. In proportion as a man has the right to derive those services from them, they are said to be his property. The whole of the services, which are capable of being derived from them, may, without much difficulty, be enumerated and classified; and when they are so, those which it may be the pleasure of the legislature to make any one's property, may be very easily and distinctly pointed out.

We may take land for an example. All the different services which are capable of being derived from the land may be enumerated, and, being classed under convenient heads, may be referred to with perfect certainty; and any portion of them, which is made the property of any individual, may thus be accurately described. A man may have a right simply to pasture a field; to pasture it for a day, or a year, or a hundred years. He may have a right to crop it; and that either in a particular manner, or in any manner he pleases; for a year, or for any other time. He may have a right to use it for any purpose, and that during a limited time, or an unlimited time. The services which it is capable of rendering may belong to him only in common with a number of other persons, or they may all belong to himself.

In illustration of this subject we may notice a classification of the services derivable from the land, made, though very rudely, by the English law. Blackstone, who, like other English lawyers, has on this, as on all other occasions, no idea of any other classification, than that which is made by the technical terms of the English law, has distinguished certain lots of the services derivable from the land, under the name of "Estates therein; Estates with respect to, 1st, Quantity of interest; 2dly, Time of enjoyment; 3dly, Number and connection of the tenants." These accordingly are, estates in fee simple, comprehending the whole of the services which are capable of being derived from the land, unlimited in point of time; estates in fee tail, implying always limitation in point of time, and often a limitation in respect to some of the services; estates for years; estates at will; estates at sufferance; estates on condition; estates in remainder; estates in reversion; estates in jointenancy; estates in coparcenary; estates in common. The Roman law has made no enumeration or classification of the services derivable from any thing, not even from the land. It speaks of property in the abstract, and in two states; property in possession, and property in action. The English law does the same thing in regard to all other property but the land. "Property, in chattels personal, is either in possession or in action," says Blackstone. He does, indeed, add, "The property

of chattels personal is liable to remainders, if created by will, to jointenancy, and to tenancy in common."

Of articles of property, different from land, the services derivable from a great number need not be divided under many heads. A piece of plate, for example, may render certain services without alteration of its form; others it may be incapable of rendering without alteration of its form. It is chiefly, therefore, by limitation of time, that the various quantities of interest in such articles need to be determined. A man's right may extend to the use of a silver cup, for a day, or a year, or for his life. During this time the different services which it is capable of rendering have no occasion to be divided. They go naturally all together. An unlimited right to its services implies the power of using it, either with or without alteration of its form, and without limitation of time. In most of the instances the limited right would be called loan, though, in the case of heirlooms and some others, there is a limited use to which the term loan is not customarily applied.

In speaking of the rights which a man may have to persons; as master, as father, as husband, and so on; there is one case so remarkable, that it requires a few words to be added in its explanation. It is that of one's own person. In this case the rights of the individual have no proper limitation beyond the obligations under which he is laid, in consequence, either of the rights conferred upon others, or of the means which are thought necessary for the protection of those rights.

If we have enabled our readers to form a tolerable conception of what we desire to be accomplished, under the title of an enumeration, and commodious classification of the services derivable from persons and things, we have performed what we proposed. The enumeration and classification, themselves, are evidently incommensurate with the design of an article in the present work. That they are practicable may be confidently taken for granted. In fact, they amount to nothing more than a description of the different degrees in which the property of a thing may be possessed; a point which is decided upon in every legal dispute. If this be done, from time to time, for one article after another, it may be done once for all.

We have already said, that rights are powers, powers for the obtaining of certain services. We have also said, that those powers can be defined only by a reference to the services which they are the means of obtaining. When those services are enumerated and classified, what remains is easy. A right to these services must begin; and it must end. The legislature has only to determine what fact shall be considered as giving a beginning to each right, and what shall be considered as putting an end to it, and then the whole business is accomplished.

It is evident that, for the definition of rights, two things are necessary. The first is, an exact description of the extent of the right; the second is, the description of the fact which gives birth to it. The extent of the right is described by reference to the lots of services, in the title to which services, all rights consist. The facts, which the convenient

Jurisprudence.

Jurisprudence.

Secondly, a Description of the Facts which give it a beginning and an End.

enjoyment of rights has pointed out as the fittest for giving commencement to rights, have been pretty well ascertained from the earliest period of society; and there has, in fact, been a very great conformity with respect to them in the laws of all nations.

The following is an imperfect enumeration of them:—*An expression of the will of the legislature*, when it makes any disposition with regard to property; *Occupancy*, when a man takes what belongs to nobody; *Labour*; *Donation*; *Contract*; *Succession*. Of these six causes of the commencement of a right there is a remarkable distinction between the first three and the last three. The first three give commencement to a right in favour of one individual, without necessarily putting an end to a right enjoyed by any other individual. The last three give commencement to a right in favour of one individual, only by making the same right to cease in favour of another individual. When a man, by donation, gives a horse to another man, the horse ceases to be the property of the one man, by the very same act by which he becomes the property of the other; so in the case of sale, or any other contract.

It is necessary for the legislature, in order that each man may know what are the objects of desire which he may enjoy, to fix, not only what are the facts which shall give commencement to a right, but what are the facts which shall put an end to it. In respect to these facts, also, there is a great harmony in the laws of all nations.

There is first the will of the legislature. When it confers a right, it may confer it, either for a limited, or for an unlimited time. In the term unlimited time, we include the power of tradition, or transfer, in all its shapes. If the time is limited, by the declaration of the legislature, either to a certain number of years, or the life of the party, the fact which terminates the right is obvious. If a man possesses a right, unlimited in point of time, the events are three by which it has been commonly fixed that it may be terminated; some expression of his own will, in the way of gift or contract; some act of delinquency; or his death.

The possessor of a right, unlimited in point of time, may, in the way of gift or contract, transfer his right either for a limited or for an unlimited time. Thus the owner of a piece of land may lease it for a term of years. He may also, in this way, convey the whole of the services which it is capable of rendering, or only a part of them. In this transaction, one event gives birth to a right in favour of the man who receives the lease, and terminates a right which was possessed by the man who gives it; and another event, namely, the arrival of the period assigned for the termination of the lease, terminates the right of the man who had received the lease, and revives his former right to the man who gave it.

Acts of delinquency have been made to terminate rights, by the laws of most nations, in the various modes of forfeiture and pecuniary penalty.

The mode in which the event of death should terminate rights has been variously regulated. Sometimes it has been allowed to terminate them simply; and what a man left at his death was open to the first occupant. All but rude nations, however, have de-

termined the persons to whom the rights which a man possessed without limitation of time shall pass at his death. The will of the former owner, when expressed, is commonly allowed to settle the matter. When that is not expressed, it has by most legislators been regulated, that his rights shall pass to his next of kin.

What is the extent of each right; by what event it shall receive its commencement; and by what event it shall be terminated;—this is all which is necessary to be pre-determined with respect to it. To do this is the duty of the legislature. When it is done, the inquiry of the judge is clear and simple. Does such a right belong to such a man? This question always resolves itself into two others. Did any of the events, which give commencement to a right, happen in this case? And did any of those events which terminate a right not happen in this case? These are questions of fact, as distinguished from law; and are to be determined by the production of evidence. If a man proves that an event which gives commencement to a right happened in his case, and if another man cannot prove that an event which terminates a right happened subsequently in that case, the right of the first man is established.

If we have now ascertained the importance and practicability of a civil code, and have shown what is to be done in order to obtain the benefit of it, we shall conclude, with some confidence, that we have rendered a great service to mankind. We proceed to the consideration of the penal code. The object of that code is, the acts by which rights may be violated.

In the term violation, we include all those acts by which the powers, conveyed by a right, are prevented from operating according to the will of the owner.

With respect to a part of such acts, all that is found convenient to do, through the instrumentality of judicature, is, to remove the obstruction, which prevents the enjoyment of the right, without inflicting any penalty for creating it. Thus, if a debt is not paid when due, the right is violated of the man who ought to receive it. Enough, however, is in this case supposed to be done, if the man, by whom the debt is due, is constrained to make payment. The act of secretly abstracting, with a view to appropriate a property, perhaps, of less value, would be an act which the laws of all nations would punish as theft.

Of injurious acts, those alone, to the commission of which it has been deemed expedient that penalties should be annexed, are considered as the object of the penal code. Of injurious acts so perfect an analysis has been performed by Mr Bentham; so perfectly, too, have the grounds been laid down upon which those acts which are destined for punishment should be selected from the rest; and so accurately have the principles, according to which punishment should be meted out, been displayed by that great philosopher, that, on this part of the subject, the philosophy of law is not far from complete.

As acts are declared to be offences, and are made subject to punishment, solely for the protection of rights, it is evident, that all acts which enter into the consideration of the penal code, are acts which in-

Jurisprudence.

What is necessary to the Perfection of the Penal Code.

Acts meet for Punishment.

Jurisprudence.

fringe upon rights, either directly, or indirectly. Those which infringe upon rights *directly*, are those by which injury is done to some individual or individuals; a blow, for example, an act of theft, and so on. We include also, under this division, all acts the *effects* of which infringe immediately upon rights; destroying a mound, for example, to inundate the lands of another man; importation of infection, by which the health or lives of others may be destroyed. Those acts by means of which rights are affected *indirectly*, are those which bear immediately upon the means which the state has provided for the protection of rights. The means which the state has provided for the protection of rights, are the operations of government generally. All acts, therefore, meet for punishment, are acts which disturb either individuals in the enjoyment of their rights, or the operations required for the protection of those rights. The latter, though mediately, and not immediately hurtful, are apt to be more extensively mischievous than the former. An act which infringes upon a right immediately, is, comparatively injurious only to one individual, or a small number of individuals; an act which prevents any of the operations of government from proceeding in its natural course is injurious to all those individuals to whose protection the due course of that operation is useful. Permit acts which interrupt all the operations of government, and all rights are practically destroyed.

If, as it thus appears, acts are meet for punishment, only because they infringe upon a right, or because they interrupt the operations provided for the protection of rights, it is evident, that, in the definition of one part of those acts, must be included the specification of the right which is infringed; and, in the definition of the other, must be included the specification of the operation disturbed. Before, therefore, an accurate penal code can exist, there must exist an accurate civil code, and also what we may call a constitutional or political code; the latter consisting of an accurate definition of the powers created for the purposes of government, and of the limitations applied to their exercise.

What is required to the Definition of an Offence.

From what has been said, it may appear, that the definition of offences, by which name we shall hereafter distinguish punishable acts, consists necessarily of two parts. The first part is the specification of the right infringed, or the operation of government disturbed; and the second part is the definition of the mode. Thus, for the definition of an act of theft, the right which the act has violated must be distinctly marked, and also the mode in which the violation has been made. In the same class of offences; as those against property, for example; the mode in which the violation is performed is that chiefly which constitutes the difference between one offence and another. In a theft and a robbery, for example, the right violated may be exactly the same; the mode in which the violation was effected constitutes the difference.

For several purposes of the penal code, it is useful, that, in the specification of the right violated, the value of what has been violated, in other words, the amount of the evil sustained, should sometimes be included. It is evident, that the value of rights can

Jurisprudence.

be judged of ultimately, only by a reference to human feelings. Of these feelings, however, certain outward marks must be taken as the standard. In offences which concern property the modes of valuation are familiarly known. In injuries to the person, those marks which denote injuries, regarded by mankind in general, as differing in magnitude; the size, for example, or position, of a wound; in injuries to reputation, the words used, and the occasion when, and so forth, are the only means of distinction which can be employed.

It may be necessary also to remark, that, in that part of the definition which relates to the mode, are to be distinguished the parties, when more than one, who engage in the same offence with different degrees of criminality; meaning, by different degrees of criminality, nothing more than demand for different degrees of punishment. The chief classes of such persons are those of principals and accessaries; and of accessaries both those before and those after the fact.

In the definition of the mode, the act is to be described in its ordinary shape. The act, however, may be attended with aggravating circumstances on the one hand, or extenuating circumstances on the other: presenting a demand for increased punishment in the first case, and diminished punishment in the second. Mr Bentham has logically remarked, that the circumstances which are to be regarded as aggravating, and the circumstances which are to be regarded as extenuating, being pretty nearly the same in all cases, they may be defined, in a separate chapter, once for all. This being done, the code proceeds in the following manner:—The definition is given of the offence in its ordinary shape, and the appropriate punishment is annexed; then immediately follows the same offence with aggravating circumstances; punishment so much the more severe: the same offence with extenuating circumstances; punishment so much the less.

Thus far we have spoken of the definition of offences, into which we have entered the less in detail, because we do not think there is much of controversy on the subject. Many persons, who doubt the possibility of framing a civil code, though, after the preceding exposition of the subject, it is a doubt which could not, we should imagine, very easily maintain itself, allow, that offences may all be defined; and that it is possible to prevent the monstrous iniquity of punishing men for acts or offences which they have not the means of knowing to be so.

After offences comes the consideration of the punishment to be annexed to them. This is a subject of considerable detail; it has been, however, so fully and admirably treated by Mr Bentham, that only some of the more general considerations, necessary to mark out the place and importance of the topic, need here to be introduced.

When a right has been infringed, there are two things, it is evident, which ought to be done: The injury which has been sustained by the individual ought to be repaired: And means ought to be taken to prevent the occurrence of a like evil in future.

The doctrine of Satisfaction is not at all difficult, as far as regards the regulating principles; the com-

The Doctrine of Punishment.

Jurisprudence.

plication is all in the detail. The greater number of injuries are those which concern property. A pecuniary value can generally be set upon injuries of this sort; though it is not very easy to determine the *pretium affectionis*, a matter of considerable importance, which the English law, so much made up of clumsiness in one part, and false refinement in another, wholly overlooks. For injuries to the person, also, it is most frequently in the pecuniary shape alone that any compensation can be made. In making these estimates, some general marks are all that can be conveniently defined by the law, and a considerable discretion must be left to the judge. Indeed, the question of damages is always a question of fact, which must be determined by the evidence adduced to the individual instance.

It accords with the feelings of every man to say, that he who has committed an injury, should be made to repair it. One part of punishment, therefore, ought, wherever special reason does not forbid, to consist in making satisfaction to the party injured. Pecuniary satisfaction, where the delinquent is rich, may be a small part of the due punishment; still, however, there is an obvious propriety, in making it a part so far as it can go. In the cases in which the delinquent has no property, there is the same propriety in making his labour subservient to that end. Hard labour, with the most economical fare, till the produce of the labour equals the amount of the satisfaction required, is, therefore, a species of punishment recommended by the strongest considerations. It is not said that labour so limited would always be sufficient punishment, and there are many cases in which it would be too much; but even then it should go as far as it can in the one case, and as far as it ought in the other.

When the injury is done to reputation, there is a manifest propriety in making the injurer contribute to the reparation, wherever it can be done. In many of the cases, too, the proper mode is abundantly obvious; all those, for example, where the publication of falsehood is the injurious act. The author of the injury may, in a way as public as that of the offence, and as well calculated as possible for the reparation of the injury, be obliged to declare that he has been solemnly adjudged to have propagated a falsehood, and is condemned to publish his own shame.

In the case of those offences which affect rights indirectly, namely, by affecting the securities provided for them, satisfaction seldom can have any place, because not any determinate individual or individuals have sustained an injury.

Thus much may suffice, in exposition of the first thing which is desirable, where an injury has been committed; namely, that reparation should be made. The second is, that measures should be adopted for preventing the future occurrence of similar events.

Punishment.

Acts are performed, only because there are motives to the performance of them. Of course injurious acts are performed, only because there are motives to the performance of them.

Corporal restraint being out of the question with regard to all the members of the community, it is evident that only two means remain for preventing

injurious acts; either, first, to take away the motives which provoke to them; or, secondly, to apply motives sufficient for the prevention of them.

Jurisprudence.

From the very nature of many of the acts it is impossible to take away the motives which provoke to them. From property stolen it is impossible to detach the value of the property; from vengeance it is impossible to detach the hope of that relief which is sought by the blow that is aimed.

What is wanted, then, is a sufficiency of motive in each instance to counteract the motives which lead to the crime. Whatever the motives, of the alluring kind, which lead to an act, if you give stronger motives of the same kind to abstain from the act, the act will, of course, be prevented. The man who would steal from you L.5 will assuredly not do so, if he knows that he shall receive L.6 for abstaining.

The question may then be started, Why should not all crimes be prevented in this way, since reward is much more desirable and humane than punishment? The answer is most satisfactory, and is built upon a ground which ought to receive profound attention on many occasions on which it is treated with the most perfect disregard. No reward can be given to one man, or set of men, but at the expence of some other man, or set of men. What is reward to one is therefore punishment to others. If L.6 be given to the man who would steal L.5, it must be taken from some one or more individuals of the community. If one man is elevated by any title or distinction, all the rest are with regard to him degraded and depressed. This is utterly unavoidable. The one event is necessarily included in the other. The giving of rewards, therefore, is a matter of serious consideration. It is not that simple act, that pure effusion of humanity, which it is often so fraudulently given out to be, and so credulously and foolishly admitted to be.

Other reasons, which prove the insufficiency of rewards for preventing injurious acts, are too obvious to require to be mentioned. We shall not therefore dwell upon this topic. This at least is sufficiently evident, that, to counteract the motives which lead to the commission of an act, we have but two methods. If we cannot apply motives, of the pleasurable sort, to induce the party to abstain from committing the act, we must apply such motives, of the painful sort, as will outweigh those which prompt to the performance. To prevent, by such means, a theft of L.5, it is absolutely necessary to affix to that act a degree of punishment which shall outweigh the advantage of possessing L.5.

We have now, it is evident, obtained the principle by which punishment ought to be regulated. We desire to prevent certain acts. That is our end, and the whole of our end. We shall assuredly prevent any acts, if we attach to them motives of the painful kind, sufficient to outweigh the motives of the opposite kind which lead to the performance. If we apply a less quantity of evil than is sufficient for outweighing those motives, the act will still be performed, and the evil will be inflicted to no purpose; it will be so much suffering in waste. If we apply a greater quantity of evil than is necessary, we incur a si-

Jurisprudence.

milar inconvenience; we create a quantity of evil which is absolutely useless; the act, which it is the tendency of the motives of the pleasurable kind to produce, will be prevented, if the motives of the painful kind outweigh them in the smallest degree, as certainly as if it outweigh them to any degree whatsoever. As soon, therefore, as the legislator has reached that point, he ought immediately to stop. Every atom of punishment which goes beyond is so much uncompensated evil, so much human misery created without any corresponding good. It is pure unmingled mischief.

As no exact measure, indeed, can be taken of the quantity of pain which will outweigh a supposed quantity of pleasure, it is always necessary to risk going somewhat beyond the mark, in order to make sure of not falling short of it. And, in the case of acts of which the evil is very great; of the higher order of crimes, in short; it may be expedient to risk a considerable degree of excess, in order to make sure of reaching the point of efficiency.

In estimating the quantity of evil which it may be necessary to create, in order to compensate the motive which leads to a mischievous act, two circumstances should be taken into the account. These are, certainty and proximity. It is of the less importance here to enter far into the illustration of these topics, that they are now pretty generally understood. It is well known that the prospect of an evil which is to happen within an hour, or two hours, produces a much greater uneasiness than the prospect of the very same evil removed to the distance of years. Every man knows that he will die within a certain number of years: many are aware that they cannot live beyond a few years; and this knowledge produces no uneasiness. The effort, on the other hand, which enables a man to behave with tranquillity, on the prospect of immediate death, is supposed to be so difficult, that it is this which makes the hero. It is, therefore, of the greatest importance, that punishment should be immediate; because, in that case, a much smaller quantity of evil suffices. It is imperatively required, by the laws of benevolence, that, if evil is a necessary means to our end, every expedient should be used to reduce it to the smallest quantity possible. It is cruelty; it belongs only to a malignant nature; to apply evil in a way which demands a quantity of it greater than would otherwise have been required. Suppose a law, that no act of theft should be punished or challenged till twenty years after the commission, or till the life of the thief was supposed to be near its end. It is evident that all punishment, in this case; that death, in the greatest torture, would be nearly destitute of power. This is partly the ground of the complaint, of the little efficacy of religious punishment, though dreadful beyond expression in the degree.

The want of certainty is a defect of equal importance. If it is a matter of doubt, whether a threatened evil will take place, the imagination is prone to magnify the chance of its not happening; and, by indulgence, magnifies it to such a degree, that the opposite chance at last excites a comparatively feeble influence. This is a remarkable law of human nature, from the influence of which even the most

Jurisprudence.

wise and prudent of men are not exempt; and of which the influence is predominant in those inconsiderate minds which are the most apt to give way to the allurements of vice. To illustrate this law, the influence of the religious punishments affords the most instructive of all examples. The punishments themselves go far beyond what the imagination can conceive. It is the complaint of divines, and the observation of all the world, that, with the great body of men, the efficacy of them is exceedingly small. The reason is, that to the want of proximity is added the greatest uncertainty. If a man puts his finger in the candle, he knows that he will be punished, and immediately, by being burned. If a man commits even a heinous sin, he has no fear of receiving the religious punishment immediately, and he conceives that, in the mercy of his Judge, in repentance and faith, he has a chance of escaping it altogether. This chance his imagination exaggerates, and most men can, in this way, go on sinning with tranquillity, to the end of their days. If all punishments were as certain and immediate as that of putting a finger in the candle, the smallest quantity, it is evident, beyond what would form a counterbalance to the advantage of the forbidden act, would suffice for its prevention. If uncertainty is admitted, to any considerable degree, no quantity of evil will suffice. It is a fact, which experience has most fully established, and which is now recognized in the most vulgar legislation, that undue severity of punishment runs counter to its end. This it does by increasing uncertainty; because men are indisposed to be the instruments of inflicting evil by which their feelings are lacerated. That legislation, therefore, is bad, which does not take measures for the greatest possible degree of proximity and certainty in the punishments which it applies.

The sources are three, from which motives of the painful sort, applicable to the purposes of the legislator, are capable of being drawn.—1st. The physical; 2dly, The moral; and, 3dly, The religious.

I. Pains from the physical source may be communicated to a man through,

1. His person,
2. His connections.
3. His property.

Through his person, they may be communicated in four principal ways,—by death, disablement, restraint and constraint, simple pain.

A man's connections are either public or private; private, as spouse, parent, servant, master, &c.; public, as ruler, subject, teacher, scholar, and so on.

The modes in which a man is punished through his property need no explanation.

II. Pains, from the moral source, are the pains which are derived from the unfavourable sentiments of mankind. For the strength of the pains, derived from this source, we must refer to the writers who have treated of this part of human nature. It is sufficient here to advert to what is universally recognized, that these pains are capable of rising to a height, with which hardly any other pains, incident to our nature, can be compared; that there is a cer-

Jurisprudence.

tain degree of the unfavourable sentiments of his fellow creatures, under which hardly any man, not below the standard of humanity, can endure to live.

The importance of this powerful agency for the prevention of injurious acts, is too obvious to need to be illustrated. If sufficiently at command, it would almost supersede the use of other means. It is, therefore, one of the first objects to the legislator to know, in what manner he can employ the pains of the popular sanction with the greatest possible effect.

To know how to direct the unfavourable sentiments of mankind, it is necessary to know in as complete, that is, in as comprehensive a way, as possible, what it is which gives them birth. Without entering into the metaphysics of the question, it is a sufficient practical answer, for the present purpose, to say, that the unfavourable sentiments of men are excited by every thing which hurts them. They love that which gives them pleasure; hate that which gives them pain. Those acts of other men which give them pleasure or save them from pain, acts of beneficence, acts of veracity, and so on, they love. Acts, on the other hand, which give them pain, mendacity, and so on, they hate. These sentiments, when the state of mind is contemplated out of which the acts are supposed to arise, are transformed into approbation and disapprobation, in all their stages and degrees; up to that of the highest veneration, down to that of the deepest abhorrence and contempt.

The unfavourable sentiments, which the legislator would excite as towards forbidden acts, must, therefore, in each man, arise from his conception of the mischievousness of those acts. That conception depends upon three circumstances; 1st, The view which he himself takes of the act; 2dly, The view which appears to be taken by other people; 3dly, Every thing which operates to render more or less permanently present to his mind his own and other men's conception of its mischievousness. From these circumstances, the practical rules for applying this great power as an instrument of the legislator for the prevention of mischievous acts are easily deduced. 1. Let the best measures be taken for giving the people a correct view of the mischievousness of the act; and then their unfavourable sentiments will be duly excited. 2. Let proper pains be taken that the people shall know every mischievous act that is committed, and know its author; that, so, no evil act may, by concealment, escape the punishment which their unfavourable sentiments imply. 3. Let the legislature, as the leading section of the public, make publication of its own unfavourable

sentiments; brand the act with infamy. 4. Let the same publication of his own unfavourable sentiments be made by the judge in the shape of reprimand and other declarations. 5. The legislature may increase the effect of these declarations, where the case requires it, by symbolical marks; or 6, by personal exposure. 7. The legislature may so order matters in certain cases, that the mischievous act can be done only through another act already infamous; as when it is more infamous to break a vow to God than to make false declarations to men, a witness may be made to swear that he will tell the truth. 8. As the favourable sentiments of mankind are so powerfully excited towards wealth, a man suffers in this respect when his property is so diminished as to lessen his rank.

Jurisprudence.

III. In pointing and proportioning the apprehension of divine punishment the legislator can do three things:

1st, He can declare his own apprehension, and the measure of it, which should be as exactly proportioned as possible to the mischievousness of the acts:

2dly, He can hire other people to declare similar apprehensions, and to make the most of the means which are available for their propagation:

3dly, He may discountenance the pointing of religious apprehensions to any acts which are not mischievous; or the pointing of them to acts which are slightly, in a greater degree, than to acts which are deeply mischievous. Whatever power of restraining from mischievous acts may be lodged in religious apprehensions, is commonly misapplied and wasted. It would be worth the cost, therefore, of pretty forcible means to prevent such a misapplication and waste of religious fears.*

In drawing from one, or more, of all these sources, a lot of punishment adapted to each particular case, the following properties, desirable in a lot of punishment, ought to be steadily borne in view. Every lot of punishment ought, as much as possible, to be,

1. Susceptible of gradation, so as to be applicable in different degrees.
2. Measurable, that the difference of degrees may be duly ascertained.
3. Equable, that is, calculated to operate not with different intensity upon different persons.
4. Such, that the thought of the punishment may naturally excite the thought of the crime.
5. Such, that the conception of it may be naturally vivid and intense.
6. Public, addressed to the senses.
7. Reformatory.
8. Disabling; viz. from crime.

* Nothing which can in any degree interfere with the rights of conscience, including whatever interpretation any man may put upon the words of Scripture, is here understood. It is the object of the legislator to encourage acts which are useful, prevent acts which are hurtful, to society. But religious hopes and fears are often applied, not to promote acts which are useful, prevent acts which are hurtful, to society; in which way, alone, they are capable of conducing to the views of the legislator; but to mere ceremonies. And cases are not wanting in which they are applied to produce acts that are hurtful, prevent those that are useful, to society. As far as religious motives are attached to the useful, instead of the useless or hurtful objects, society is benefited. It is this benefit which it is recommended to the legislator to pursue.

Jurisprudence.

9. Remediable; viz. if afterwards found to be undeserved.

10. Compensative; viz. to the party injured.

11. Productive; viz. to the community, as labour.

Of all the instruments of punishment which have yet occurred to the ingenuity of man, there is none which unites these desirable qualities in any thing like an equal degree with the *Panopticon Penitentiary*, as devised and described by Mr Bentham.

One general rule applies in the case of all the lots of punishment. It is this: That the private good which has operated as the motive to the injurious action, should, in all possible cases, be cut off, and the expected enjoyment prevented. Where this can be done completely, all the additional punishment necessary is only that which would suffice to compensate the want of certainty and proximity in the act of deprivation; for no man would commit a crime which he was sure he could not profit by; no man would steal, if he knew that the property stolen would that minute be taken from him. The interests which are capable of being promoted by a criminal act, may be summed up under the following titles:

1. Money, or money's worth.
2. Power.
3. Revenge.
4. Vanity, emulation.
5. Sensual pleasure, chiefly venereal.
6. Safety in respect to legal punishment.

With respect to four of these interests, viz. money, power, vanity, and safety in respect to legal punishment, the contemplated benefit is capable, in many cases, of being completely intercepted. In the case in which revenge has operated through the degradation of the party suffering, the evil doer may be disappointed by re-exaltation of the degraded party. Sensual pleasure, having been enjoyed, is beyond the reach of this operation. It is highly worthy of observation, that, among the advantages constituting the motives to crime, those which can be cut off, and from the enjoyment of which the offender can be prevented, constitute by far the most frequent incentives to crime.

This must suffice as a summary of what should be said on the mode of applying pain most usefully for the prevention of certain acts. It only remains to add, that the following are the cases in which it may be pronounced unfit that pain should be employed for that purpose:

1. Where the evil to the community does not overbalance the good to the individual.
2. Where the evil necessary for the punishment would outweigh the evil of the act.
3. Where the evil created is not calculated to prevent the act.
4. Where the end could be obtained by other means.

● The Code of Procedure.

We have now, therefore, stated what the limits of this discourse enable us to adduce, on the subject of the main body of the law; the enactments of the legislature with respect to rights, and with respect to those acts by which rights are violated. It remains

VOL. V. PART I.

Jurisprudence.

that we consider that subsidiary branch of law, by which an agency is constituted for the purpose of carrying those enactments into effect. The inquiry here is, what are the operations essential to that agency; by what agents are they most likely to be well performed; and what are the best securities that can be taken for the good conduct of these agents.

It most significantly illustrates the manner in which ignorance gropes its way in the dark, to observe, that the agency, the sole end of which is to carry into execution the civil and penal laws, was created first, and was in operation for ages, before even the idea of the other branches of law was even tolerably framed. It is also worthy of remark, that the men, whose wisdom rules our affairs, are in the habit of calling the mode in which ignorance gropes its way in the dark, by the name of experience; the mode of acting upon a plan, and with foresight, by the names of theory and speculation.

There is instruction in observing the mode in which this inverted course of law-making was pursued. Men disputed; and their disputes were attended with the most destructive consequences. Originally, the king, at the head of the military force, and his subordinates, each at the head of a section of that force, interfered in those disputes. After a time, the king appointed functionaries, under the name of judges, for that particular service. These judges decided, without any rule, by their own discretion. The feelings of the community, grounded upon their experience of what tended to good and evil upon the whole, pointed vaguely to certain things as right, to other things as wrong; and to these the judge, as often as he was in *bona fides*, conformed his decision. The mode was similar both in arbitrating and in punishing.

As punishing, especially in the severer cases, was an act which made a vivid impression upon the mind, the mode in which that act had been performed in previous cases was apt to be remembered; of the several modes, that which was most approved by the public would naturally be followed the most frequently, and at last there would be a species of scandal, if it was unnecessarily departed from. In this way a uniformity, more or less perfect, was established, in punishing the more heinous offences; and in regard to them custom first established what had some feeble portion of the attributes of a law.

In those cases in which, without a call for punishment, the authoritative termination of a dispute was all that was required, the experience of what was necessary, not only for any degree of mutual comfort, but even for the means of subsistence, soon established a few leading points of uniformity. Thus, when a man had cultivated a piece of ground, which belonged to nobody more peculiarly than to himself, it was evidently necessary that the crop should be considered as belonging to him; otherwise, no crops would be raised, and the community would be deprived of the means of subsistence.

These general feelings, with the remembrance, more or less perfect, of what had been done in similar cases, were the only guide; and it is surprising to what an extent, over the surface of the whole

Jurispru-
dence.

globe, law has, in all ages, remained in that state of imperfect existence, if, indeed, with any propriety, it can be called a state of existence. In every part of Asia, and in all ages, law has remained in that state of existence, or non-existence. In Europe, where, at a pretty early period, it became the practice to record in writing the proceedings of the judges, the natural propensity of referring to the past as a rule for the present, begat in time a species of obligation of being directed by the examples which had already been set. This created a uniformity and certainty, which, however imperfect, were greatly superior to those which attended the arbitrary proceedings of Asiatic judges. Yet this was a benefit which had a dreadful alloy. A body, not of law, but of decisions, out of which, on each particular occasion, a law for that particular occasion, as out of the crude ore, was to be smelted, hammered, and wire-drawn, was the natural material out of which to manufacture a system of chicanery. How accurately the system of law, in the several nations of Europe, has conformed to the character of a system of chicanery, is matter of present and lamentable experience. The uncertainty, the delay, the vexation and expence, and that immorality of the worst species with which they inundate the community, are not the only evils, great as they are, of laws constructed upon such a plan. A system of laws, so constructed, becomes an instrument of conservation for the barbarous customs and ideas of the times in which they were engendered; and infests society with evils of another age.

To conceive the operations which are necessary to give effect to the enactments of the legislature, it is necessary to conceive the occasions which call for them.

When the legislature has established rights, so long as there is no dispute about those rights, and so long as there is no complaint of any violation of them, so long there is no occasion for any agency to give to the enactments of the legislature their effect. The moment, however, one person says, the right to that object is mine, and another person says no, but the right to that object is mine; or the moment any man complains that such or such a right belonging to him another man has violated, that moment occasion for the agency in question begins.

It is evident, also, that the operations necessary to give effect to the enactments of the legislature are confined to those two occasions, namely, that on which a right is disputed, and that on which it has been violated. On the occasions on which a right is disputed, it is requisite to determine to whom it belongs. On the occasions on which a right has been violated, it is sometimes only required to compel reparation to the injured party; sometimes it is necessary, besides, to inflict punishment upon the offender. The question is, What are the operations required for these several results?

Where a right is disputed, all possible cases may be resolved into that of A who affirms, and B who denies. That right is mine, says A, it is not yours, says B.

The first question to be asked of A is, which, among those facts, which the legislature has deter-

mined shall give commencement to rights, happened in such a manner as to give commencement to that which is claimed as a right by him.

If no such fact is affirmed, the right does not exist. If some such fact is affirmed, it may be met by the opponent in one of two ways. B either may deny the fact, and affirm that the right never had a commencement; or he may allow the fact, and admit that the right had a commencement, but affirm that there had subsequently happened one of those facts which put an end to rights; admitting that A bought the horse, and had a right to him in the month of July, he might affirm that A sold him again in August, and by that transaction put an end to his right.

When B meets the affirmation of A in the first way, that is, by denying the commencement of the right, he may do it in either of two ways. He may deny the investitive fact which A affirms, or not denying the fact, he may affirm some antecedent fact which deprived it of its investitive power. Thus, if A affirmed that he got the property by occupancy, B may affirm that it was not open to occupancy, but the property of another person. If A affirmed that he got the property by succession to his father, B may allow the fact of the succession, but affirm that the property did not belong to the father of A at the time of his death.

Whenever the legislature has accurately determined what are the facts which shall give commencement, and what those which shall give termination to a right, the whole confused and intricate mass of what in English law is called *Pleading*, reduces itself to these clear and simple elements. A begins, by affirming some one of the facts which gives commencement to a right. B may deny this fact directly; A affirms contract for example, B denies it; and then, of course, comes the evidence: Or, instead of denying it, B may affirm an antecedent fact which deprived the fact affirmed by A of its investitive force; or he may affirm a subsequent fact, which put an end to the right. In those two cases, in which B affirms a new fact, A must be called upon for a reply. In other words, asked whether he admits or denies it. If he admits, there is an end, of course, to the claim of A. If he denies, then again we have affirmation and denial upon a matter of fact, which is to be determined by the production of evidence.

This is the first part of the proceeding, neither intricate nor obscure. The next is, the adduction of evidence. A fact is disputed; affirmed on the one side, denied on the other. A produces evidence to prove the fact, B produces evidence to disprove it. The decision is on the one side or the other, and the dispute is at an end.

If both parties obey the decision, there is no occasion for another act. If the losing party disobeys, force is necessary to compel obedience. This is called execution, and terminates the agency required.

It is needless to particularize a penal proceeding; all the possible varieties of which fall under one or other of the cases illustrated.

Thus, when a man is charged with a crime, the prosecutor affirms one of the acts violating rights, to which punishment is annexed by the legislator. The

Jurispru-
dence.

Jurisprudence.

defendant can meet this affirmation in one of only two ways. First, he may deny the act, and then the second stage of proceeding, the adduction of evidence, immediately takes place. Or, not denying the act, he may affirm some previous act, which prevented it from having the effect of violating a right. Not denying the fact of taking the horse out of the field with a view to appropriate him, he may affirm a previous purchase, gift, &c. The adduction of evidence has nothing peculiar in the case of a penal proceeding at law. In the last stage, that of execution, the peculiar act of inflicting punishment is required.

Having thus a view, though very summary, of the operations required, we shall be the better able to judge of the agents necessary for the performance.

The stages, we have observed, are three. The first is that in which the plaintiff adduces the investitive fact on which he relies, and is met by the defendant either with a denial of the fact, or the affirmation of another fact, which, to maintain the suit, the plaintiff must deny. The second is that in which evidence, to prove or disprove the fact on which the affirmation and denial of the parties ultimately rests, is adduced and decided upon. The third is that in which the operations are performed necessary for giving effect to the sentence of the judge.

First Stage of the Judicial Business.

What is desirable in the operations of the first stage is, 1st, That the affirmations and negations with respect to the facts should be true; and, 2dly, That the facts themselves should be such as really to have the investitive or divestitive quality ascribed to them. For the first of these purposes, all the securities, which the nature of the case admits of, should be taken, for the veracity of the parties. There is the same sort of reason that the parties should speak truly, as that the witnesses should speak truly. They should speak, therefore, under all the sanctions and penalties of a witness. They cannot, indeed, in many cases swear to the existence or non-existence of the fact; which may not have been within their cognizance. But they can always swear to the state of their belief with respect to it. For the second of the above purposes, namely, that it may be known whether the facts affirmed and denied are such as to possess the investitive or divestitive quality ascribed to them, two things are necessary; the first is, that all investitive and divestitive facts should have been clearly predetermined by the legislature, in other words, that there should be a well made civil code; the second is, that the affirmations and denials with respect to them should be made in the presence of somebody capable of telling exactly whether they have the quality ascribed to them or not. The judge is a person with this knowledge, and to him alone can the power of deciding on matters so essential to the result of the inquiry be entrusted.

To have this important part of the business, then, done in the best possible way, it is necessary that the parties should meet in the very first instance in the presence of the judge. A is asked, upon his oath, to mention the fact which he believes confers upon him his right. If it is not a fact capable of having that effect, he is told so, and his claim is at an end. If it is a fact capable of having that effect,

Jurisprudence.

B is asked whether he denies it; or whether he affirms another fact, either one of those, which, happening previously, would prevent it from having its investitive effect, or one of those which, happening subsequently, would put an end to the right to which it gave commencement. If he affirmed only a fact which could have neither of these effects, the pretension of B would be without foundation.

Done in this manner, the clearness, the quickness, and the certainty of the whole proceeding are demonstrated. Remarkable it is, that every one of the rules for doing it in the best possible manner, is departed from by the English law, and that to the greatest possible extent. No security whatsoever is taken that the parties shall speak the truth; they are left with perfect impunity. aptly by Mr Bentham denominated the *mendacity-licence*, to tell as many lies as they please. The legislature has never enumerated and defined the facts which shall give commencement, or put a period to rights; the subject, therefore, remains in a state of confusion, obscurity, and uncertainty. And, lastly, the parties do not make their affirmations and negations before the judge, who would tell them whether the facts which they allege could or could not have the virtue ascribed to them; they make them in secret, and in writing, each along with his attorney, who has an interest in making them not in the way most conducive to the interests of his client, but in the way most conducive to his own interests, and those of his confederates, from the bottom to the top of the profession. First, A, the plaintiff, writes what is called the declaration, an instrument for the most part full of irrelevant absurdity and lies; and this he deposits in an office, where the attorney of B, the defendant, obtains a copy of it, on paying a fee. Next B, the defendant, meets the declaration of A, by what is called a plea, the form of which is not less absurd than that of the declaration. The plea is written and put into the same office, out of which the attorney of the opposite party obtains a copy of it on similar terms. The plea may be of two sorts; either, 1st, a dilatory plea, as it is called; or, 2dly, a plea to the action. To this plea the plaintiff may make a *replication*, proceeding through the same process. To the replication the defendant may put in a *rejoinder*. The plaintiff may answer the rejoinder by a *sur-rejoinder*. This, again, the defendant may oppose by a *rebuttal*, and the plaintiff may answer him by a *sur-rebuttal*.

All this takes place without being once seen or heard of by the judge; and no sooner has it come before him, than some flaw is perhaps discovered in it, whereupon he quashes the whole, and sends it to be performed again from the beginning.

This mischievous mess, which exists in defiance and mockery of reason, English lawyers inform us, is a strict, and pure, and beautiful exemplification of the rules of logic. This is a common language of theirs. It is a language which clearly demonstrates the state of their minds. All that they see in the system of pleading is the mode of performing it. What they know of logic is little more than the name.

The agency necessary for the performance of this

Jurisprudence.

stage of the business, is some person, who, when he hears a fact affirmed or denied, can tell whether it is one of those facts to which the legislature has attached the power of giving commencement or of putting a period to rights. It is evident, that on such occasion, any one person, with the requisite knowledge, attention, and probity, is as competent to the task as a hundred. If he is single, the attention and probity is likely to be the greatest, as responsibility is not weakened merely, it is almost annihilated by being shared. There should be one Judge, therefore, and not more, to superintend that branch of procedure which consists of pleading.

Second stage of the Judicial Business.

The agency best adapted to the business of the second stage of judicature, is that which next demands our attention. The business of that stage is, the taking of evidence; in other words, the doing all that is necessary to ascertain whether the disputed fact happened or did not happen.

The subject of evidence is a matter of complexity in the detail. And where any thing complex is to be stated in words, there is always difficulty in the expression, how plain soever the ideas. Such general considerations, however, as we can even here adduce, will, we hope, throw sufficient light upon the subject, to leave no doubt with respect to the conclusions which we have it in view to establish. This is one of the topics, connected with law, which Mr Bentham has exhausted, though a small part only of what he has written upon it has yet seen the light.*

With respect to all facts, legally operative, that is, which give or take away rights, it is desirable that evidence, amounting to proof, should, if possible, always exist. With respect to a great proportion of them, it is in the power of the legislature to take measures, that evidence of them shall be collected at the moment of their happening, and shall be preserved. This is the case with all those of which an evidentiary writing can be made and preserved by registration; all contracts, births, deaths, marriages, and so on. The proportion is really very great of the whole number of facts, legally operative, in regard to which a legislature, by proper means, might secure the existence of evidence, and to that extent might either prevent disputes, or render the decision of them easy. That so little of this most important and obvious work has any where been done, only shows how ill the legislatures of the world have hitherto performed the task. It is in the power of the legislature, by a proper classification, to have an accurate formulary, for the different species of *contracts, mills, and other evidentiary writings*. Those formularies, properly made and printed with blanks to fill up, would render the business of *Conveyancing*, which, in England, is a boundless, trackless, and almost impenetrable jungle, abounding with expence, with delay and vexation to parties, with wealth and almost boundless power over the fortunes of other men to lawyers, a thing of the greatest simplicity, certainty, and ease.

Into the question of what might be, and ought to be done by the legislature, for making and preserving evidence of the principal facts by which rights are made to begin or to end, we cannot enter at length, on the present occasion. The great importance which belongs to the subject, is evident from what we have thus shortly advanced.

The business of him who is only called upon to determine whether a disputed fact did or did not happen, is, to make the best use of all the evidence which exists; whether it were, or were not desirable, that more had been made to exist. For the best use of that which exists, three things are necessary:

1st, That the whole of it should be made to bear, that is, should be taken and applied.

2dly, That it should be taken in those circumstances, which are most conducive to trust-worthiness.

3dly, That the proper value should be set upon each article, and upon the whole.

1. That the evidence may be taken as completely as possible, two things are necessary. The first is, that the judge should have power to send for, and to compel the attendance of, all persons and things which may be capable of affording evidence. The second is, that the evidence should all be taken, and nothing be omitted or lost.

It is not necessary here to enter into any details with respect to the first of those requisites. The necessity of the powers is obvious, and the end to be attained is so precise and perspicuous, that there can be no difficulty in conceiving the mode of putting together and applying the means. There is no limit, it is obvious, to the physical power which should be placed at the disposal of the judge. He ought to have the right of calling upon every man upon the whole community, to aid him in any act which is necessary to the performance of any part of his judicial duty; because any force, opposed to the performance of that duty, there ought to be a force sufficient promptly to overcome. It is convenient, however, to the community, instead of being liable to be called upon, individually, for the performance of the ordinary services auxiliary to the business of the judge, to provide him with a proper number of officers, paid for attending to execute his commands. Their principal business, as regards this stage of the judicial proceedings, is, to serve notice upon any persons whose own presence, or that of any writing or other thing which they may possess, is required by the judge. Persons or things, subjected immediately to the operations of judicature, have a particular name in English. They are said to be *forthcoming*, a word which has an exact equivalent in few other languages, and is exceedingly appropriate and useful. It is of the greatest convenience, when a concrete term, the use of which is very frequent, has an abstract term corresponding to it; as good, has goodness; hard, hardness, and so

* We are happy to say, there are hopes that this part of Mr Bentham's writings will soon be presented to the public by M. Dumont, the first of translators and redacteurs, in that happy form which he has given to other portions of that philosopher's manuscripts.

Jurisprudence. on. There was not any word in the language corresponding in this way to *forthcoming*. Mr Bentham, perceiving the great need of it, made the term *forthcomingness*; not exceptionable on the score either of harshness or obscurity. The small wits thought proper to laugh at him. We shall, nevertheless, sorry at the same time that we cannot supply a defect in the language without offending them, make use of the word, in which we find great appropriateness and great convenience. This particular branch, therefore, of the judicial agency is that which relates to *forthcomingness*; and *forthcomingness* is required for two purposes, both for evidence and for justiciability; for evidence, that a true decision may be passed; for justiciability, that the sentence of the judge may not fail of its intended effect.

So much with respect to the *forthcomingness* of evidence. The second condition, required to give the decision the benefit of all the existing evidence, is, that the whole should be taken, and that not any part of it which can be taken without preponderant inconvenience should be excluded and lost.

Of the several articles of evidence, some will always be of more importance; some of less; and some may be of very little importance; but whether of little or of much, it is always desirable that all should be taken, and every the smallest portion counted for what it is worth. The discovery of truth is promoted by taking advantage of every thing which tends to throw light upon the subject of dispute.

These propositions, it may appear to be useless, indeed impertinent, formally to state. They are too evident, it may be said, to be disputed, and too important to be overlooked. Important as they are, and undisputed by all the rest of the world, they are not only disputed, but trampled upon by lawyers, especially English lawyers. They have unhappily established a set of rules in direct opposition to them. These rules they applaud in all forms of expression, and celebrate as guards and fences of all that is dear to mankind.

In all causes, they have determined, that persons so and so situated, things so and so situated, though apt to be pregnant with information beyond all other persons and things, shall not be admitted as sources of evidence. Thus, in English law, we have incompetency of witnesses, that is, exclusion of them, *1st*, From want of understanding; *2dly*, From defect of religious principle; *3dly*, From infamy of character; *4thly*, From interest. These are undisguised modes of exclusion; besides which, there is an extensive assortment of disguised modes. Under this title come the rule, that only the best evidence be given which the nature of the case admits of; according to which, it often happens that the only evidence which can be had is excluded. Under this title also falls the rule, making certain kinds of evidence conclusive, by which proceeding, all other evidence is excluded. To the same list belongs the rule, that hearsay evidence is not admissible. The rules, so extensive in their application, by which writings are wholly rejected, only because they want certain formularies, are rules of exclusion; and so are the limitations with respect to time, and to number of witnesses. Into the very extensive subject, however,

of the absurdity and mischievousness of the rules of evidence in English law, we cannot pretend so much as to enter. A remarkable exemplification of them was afforded on the trial of Warren Hastings, to which, for this purpose, the reader may be referred. (See Mill's *History of British India*, Book VI. Chap. ii.)

The only conceivable reasons for the exclusion of evidence are three:

1. Irrelevancy.
2. Inconvenience in obtaining and producing.
3. Danger of deception.

With regard to irrelevancy, the decision is clear. What has no tendency either to prove or disprove the point in question, it would be loss of time to receive.

With regard to inconvenience, it is no doubt liable to happen, that when all the good which can be expected from the obtaining of a lot of evidence is compared with the evil of the delay, cost, and vexation, inseparable from the obtaining of it, the evil may be more than an overmatch for the good. In all such cases, it is expedient that the lot of evidence should be foregone.

As a guard against the danger of deception, it is equally certain that no evidence ought ever to be excluded. An account of all the reasons by which the absurdity is demonstrated of exclusion on this ground, and of the wide and deplorable mischief which, in the vulgar systems, is produced by it, would be far too extensive for the contracted limits of the present discourse. Reasons, however, decisive of the question, present themselves so obviously, that hardly any man, with an ordinary understanding, not fettered by prejudice, can look at the subject without perceiving them.

If evidence is to be received from no source from which evidence, liable to produce deception, is capable of coming, evidence must not be received at all. Evidence must be received from sources whence false evidence, as well as true, is liable to flow. To refuse all information from such sources, is not the way by which a knowledge of the truth can be obtained. This is the way to make sure of not having that knowledge. The means of obtaining it are, to receive information from every possible source, and to separate the bad from the good, under all those securities, and by the guidance of all those marks, of which understanding and attention know how to avail themselves.

It is not enough to say, we will receive information from those sources only which are least likely to yield deceptive evidence, refuse to receive it from those which are most likely. You are obliged to receive it from sources differing in almost all possible degrees of likelihood. Where are you to draw the line of separation? Is not the same discernment which guards you against the danger of false information from the sources which you deem the least likely to yield it, sufficient to guard you against it from those sources which you deem the most likely to do so? In fact it will be still more sufficient, because in this case you will be much more apt to be upon your guard. The very best information is, in truth, liable to be derived from the very worst of

Jurisprudence.

Jurisprudence.

sources,—from a man who, you know, would not tell you one word of truth, if he could help it.

The securities that a man will give true information, independently of those artificial securities which the legislature can apply equally to all, are, 1st, Intelligence. 2d, Probity. 3d, Freedom from interest. Suppose that one or two, or all of these securities are wanting; it only follows that what he states should be heard with a proportional distrust. It may still be of the utmost importance to the discovery of the truth that he should be heard. It never can be less than unfavourable to that great end that, with the proper allowances, he should not be heard at all. His testimony may appear, when heard, to be utterly unworthy of credence. But that could not be known till it was heard and examined. It might so have been, that it was not only worthy of credence, but completed the proof of a fact of the greatest possible importance. That a man should not be heard as a witness, on account of his religious creed, is an absurdity which we cannot descend to notice.

2. The second of the three things which we found necessary, as above, for making the best use judicially of whatever evidence, to the fact in question, exists, was, that it should be taken under those circumstances, which are most conducive to trust-worthiness. Those circumstances are constituted by the artificial securities, which arrangements can be made to apply. The following enumeration of them has been made by Mr Bentham (*Introduction to the Rationale of Evidence*, p. 54), and appears to be complete.

1. Punishment.
2. Shame.
3. Interrogation, including counter-interrogation.
4. Counter evidence,—admission of.
5. Writing,—use made of it for giving permanence, &c. to evidence.
6. Publicity,—to most purposes and on most occasions.
7. Privacy,—to some purposes, and on some occasions.

For developing the import of these several securities, we can afford to say nothing. The principal operation of the judicial functionary in this part of the business is, to preside over the interrogation; to see that it is properly and completely performed. The question, then, what is the sort of agency best adapted for the performance of this part of the task of taking evidence, is not difficult to answer. There is nothing in it which one man, with the proper intellectual and moral qualifications, is not as capable of performing, as any number of men.

3. All the existing evidence being collected and received, it only remains that the proper value should be attached to the several portions, and a corresponding decision pronounced.

It is sufficiently evident that, for the performance of this duty, no very precise instructions can be laid down. The value which belongs to an article of evidence often depends on minute and almost indescribable circumstances; and the result must be left to the sagacity and conscience of the judge.

At the same time, however, service to this end,

and of the greatest importance may be, and, of course, ought to be, rendered by the legislature. The different marks of trust-worthiness may, to a certain extent of particularity, be very correctly described. This being done, the difference between the value of any two lots of evidence, to which those marks attach, may be very exactly ascertained. One has a certain number of the marks of trust-worthiness, as laid down by the legislature; another has all these and so many more; the result is clear. It is evident, that as far, in this respect, as experience and foresight can go, nothing should be left undone by the legislature.

Another important service can be rendered by the legislature; and that is, to provide an accurate language for the judge; a language in which he can express precisely the degree of value which he allots to each article of evidence, and to the whole. Various expedients may be adopted for this purpose. A very obvious one is, to fix upon some particular, well known article of evidence, the value of which all men appreciate equally; the clear testimony, for example, of a man of the ordinary degree of intelligence and probity; as a standard. Is the value to be expressed, which the judge attaches to any other article of evidence? If inferior to the standard, it falls below it by so many degrees, one, two, three, four: If superior, it rises above it by so many.

Having provided an accurate language, the legislature should take security that it be used; and admit of no vague and general expressions in the account of the value which the judge attaches to each article of the evidence on which he grounds his decision.

At the same time that the legislature insists upon the use of precise language in stating the value of evidence, it should insist upon reasons; upon receiving from the judge a precise statement of the grounds upon which he attaches such a value, and no other, to each and every article of evidence; that is, upon receiving a reference, as exact as language can give, to each of the circumstances which contributed to suggest to him that particular estimate which he says he has formed.

Of the importance of all these expedients we presume that no illustration is required.

We come now to the third and last stage of the business of judicature; when all that remains is to carry into effect the sentence of the judge.

When they, upon whom the sentence operates, are willing to obey, all that is necessary is to afford them notice of what it requires them to perform. In well ordered countries, all but a very insignificant number will be found to be cases of this description. When opposition is to be overcome, a physical force must be provided, sufficient for the purpose. As there seems nothing mysterious in determining how this should be formed, and under what rules it should act, to secure the ends for which it is provided, with the smallest possible amount of collateral evil; we shall here take leave of the subject.

We have now seen the whole of the operations to be performed. The parties are received to state before the judge the investitive or divestitive facts on

Jurisprudence.

Third stage of the Judicial Function.

Jurisprudence.

which they rely. If they state, for this purpose, a fact which is not possessed of those qualities, they are immediately told that it is not possessed of them, and not calculated to support their claim. They come, by two or three steps, at the longest, to a fact upon which the question ultimately turns; and which is either contested, or not contested. In a great many cases it would not be contested. When the subject was stripped of disguise, the party who had no right, would generally see that he had no hope, and would acquiesce. The suit would thus be terminated without the adduction of evidence. When it was not, the cases would be frequent in which it might be terminated by the evidence which the parties brought along with them. In these cases, also, the first hearing would suffice. A vast majority of the whole number of suits would be included in these two sets of cases. For the decision of a vast majority, therefore, of the whole number of suits, a few minutes would suffice. When all the evidence could not be forthcoming at the first hearing, and only then, would a second hearing be required. In this mode of proceeding, justice would be, that without which it is not justice, expeditious and cheap.

The Judicial Establishment for inquiry what the prof-ency be allowed to one tribunal.

In all this there is nothing which one man, with the appropriate intellectual and moral qualities, is not as competent to perform as any number of men. As one man is cheaper than any greater number, that is one reason why no more than one judge should be allowed to one tribunal.

The effect of Laws.

The next object of inquiry is, to ascertain what securities can be provided that those who are entrusted with the business of judicature shall possess the requisite intellectual and moral endowments.

Securities for the intellectual endowments of the Judge

The intellectual endowments depend upon those who have the power of choosing and of dismissing the judges; and who do or do not appoint men whose knowledge and capacity are ascertained. The moral behaviour of the judges depends upon the interests which act upon them in the situation in which they are placed.

Into the question, who should have the appointment of the judges, we do not intend to enter. The answer would be different under different forms of government; and this is not the place to compare the different forms of government, either for this or any other of the ends of its institution. One thing only we shall state, because it carries its evidence along with it. Those who appoint the judges ought to have no interest contrary to the best administration of justice.

Securities for the moral Qualities of the Judge

As the uprightness of the judge is assailed by interests inseparable from his situation; viz. the profit which he may derive from misdecision, it is necessary to counterbalance them by opposite interests, assuming the character of securities. Several of the securities, which we have already seen applying to the situation of witness, apply also to the situation of judge: Some are peculiar to each. The following is the list of those which apply to the situation of judge.

1. Punishment.
2. Shame.
3. Publicity.

4. Writing, for the sake of accuracy and permanence.

5. Singleness of the functionary.

6. Appeal.

Jurisprudence.

For the *Punishment* of the several kinds of judicial offences, provision ought to be made in the penal code.

In the case of the judge there is particular occasion to point accurately, and to strengthen to the utmost the operation of *Shame*; for in the situation of judge it is possible to be guilty of offences very numerous and very serious, without permitting so much of evidence to attach to any definite act, as would suffice to form a ground for punishment.

The great instrument for the application of shame is *Publicity*. The importance of publicity, therefore, is paramount. It is not only the great instrument for creating and applying the moral sanction, the approbation and disapprobation of mankind; but it is of essential service towards the application of punishment, by making known the occasions on which it is deserved. It is not only a great security in itself, but it is the principle of life and strength to all other securities.

All other publicity is feeble and of little worth compared with that of the *Press*. Not only, therefore, ought this to be allowed to operate with its utmost force upon the judge, but effectual provision ought to be made to cause it to operate upon him with its utmost force. Not only ought the judgment hall to be rendered as convenient as possible for the reception of the public; not only ought the greatest freedom to be enjoyed in publishing the proceedings of the judge; and in publishing all manner of observations upon them, favourable or unfavourable; but measures ought to be taken to make a public, and to produce publication, where there is any chance that a voluntary public, and voluntary publication, would be wanting. For this purpose, unless other very important considerations intervene, the judgment seat should always be in that place, within the district to which it belongs, where the most numerous and intelligent public, and the best means of publication, are to be had.

In England, where there is no definition of libel, and where the judges, therefore, are allowed to punish, under the name of libel, whatever writing they do not like, the publishing of unfavourable observations on the conduct of a judge; nay, in some instances, and these the highest in importance, the simple report of his proceedings—is treated as one of the most heinous of all possible offences. No wonder! Allow judges, or allow any men, to frame laws, and they will frame them, if they can, to answer their own purposes. Who would not, if he could, make a law to protect himself from censure? More especially if he were a man disposed to act in such a way as to deserve censure?

Would you allow falsehood to be published against the judge? The word falsehood is here ambiguous. It means both erroneous opinions, and false statements with regard to fact. Erroneous opinions we would undoubtedly permit, because we know no standard for ascertaining them, other than that which is afforded by public discussion; and be-

Jurisprudence.

cause this is an adequate remedy for all the evil which erroneous opinions have any tendency to produce. Affirmation of facts injurious to the judge, if false, and made without reasonable grounds for having been believed to be true, we would prevent.

Allow facts, injurious to the judge, to be published, even when true; allow comments, unfavourable to the judge, to be made upon his actions, you discredit the administration of justice. Discredit the administration of justice, to which the people are resorting every day for the greatest of all possible benefits, protection from injury! As well talk of discrediting the business of a bread-baker, a meat-seller, if the fraudulent dealer is exposed to the censures of the public! Discredit the administration of justice, indeed, by taking measures of security against the vices of judges; indispensable for its perfection!

The importance of recording, in permanent characters, what takes place before the judge, we must content ourselves with assuming. We may do so, it is presumed, with propriety, on account of the facility with which the reasons present themselves. We must also leave it to our readers to draw the line of distinction between the occasions on which it is requisite, and the occasions on which it may be dispensed with; the occasions, for example, where every thing is simple and clear, and all parties are satisfied.

It is a great security, both for diligent and for upright conduct in the judge, that he occupy *singly* the judgment seat. When a man knows that the whole credit and reward of what is done well; the whole punishment and disgrace of what is done ill, will belong to himself, the motive to good conduct is exceedingly increased. When a man hopes that he can shuffle off the blame of negligence, the blame of unfairness, or fix a part of it on another, the uncertainty of the punishment operates, as we have already seen, to the diminution, and almost to the extinction, of preventive force. Certain common, and even proverbial expressions, mark the general experience of that indifference, with which a duty, that belongs in common to many, is apt to be performed. What is every body's business is nobody's. This is as true in the family as in the state; as true in judicature as in ordinary life. Much remains to be said upon this topic, which is one of great importance; but we must pass to the next.

Of the use of *appeal*, as a security against the misconduct of the judge, there is the less occasion to adduce any proof, because it seems to be fully recognised by the practice of nations.

One thing, however, which is not recognised by that practice, is, that, if it is necessary in any one sort of causes, so it is in every other, without exception. Not a single reason can be given why it should exist in one set of cases, which is not equally strong to prove that it should exist in any other.

It is instructive to observe the cases in which it has been supposed that it ought to exist, and the cases in which it has been supposed that it might be omitted. The cases in which it has been thought necessary, are those which concern property of con-

Jurisprudence.

siderable value. Those in which it has been dispensed with are those which concern property of inconsiderable value. The first set of cases are those which are of importance to the aristocratical class; the second are those which are of no importance to that class. It is the aristocratical class who have made the laws; they have accordingly declared that the suits which were important to them should have the benefit of appeal; the suits not important to them should not have the benefit of appeal.

We recognise only one standard of importance; namely, influence upon human happiness and misery. The small sum of money for which the suit of the poor man is instituted is commonly of much greater importance to him, than the larger sum for which the suit of the rich man is instituted is to the rich. Again, for one rich man there are thousands and thousands of poor. In the calculation, then, of perfect benevolence, the suits for the small sums are not as in the calculation of perfect aristocracy, those of the least, or rather no importance; they are of ten thousand times greater importance than the suits for the largest sums.

If an appeal ought to be had, how many *stages* should there be of appeal? This question, we imagine, is easily answered. If you go for a second judgment, you should, if possible, go to the very best source; and if you go at once to the best source, why go any farther?

What is required to be done, in the case of an appeal, is the first thing which deserves to be ascertained. An appeal takes place in consequence of a complaint against the previous judge. Where no complaint, there is no appeal, nor place for appeal.

A complaint against the judge must relate to his conduct, either at the first, the second, or the third stage, of the judicial operations.

If to his conduct at the first stage, it must be a complaint of his having permitted a party to rest upon a fact which had not the investigative or divestitive quality ascribed to it; and this implies either a mistake with respect to the law, or that he allowed the decision to turn upon a fact which did not embrace the merits of the question. It is evident, that for the decision of this question, all that is necessary is an exact transcription of the *pleadings*, and transmission of them to the court of appeal.

If the complaint relates to his conduct at the second stage, it must turn upon one of two points; either that he did not take all the evidence, or that he did not properly determine its value.

If he did not take the evidence properly, by a failure either in assembling the sources of it, or in extracting it from them when assembled, the proper remedy is to send back the cause to him, with an order to him to supply the omission; or, if he be suspected of having failed wilfully, to send it to the judge of one of the neighbouring districts, to retake the evidence and decide.

If the complaint relates to a wrong estimate of the evidence, the statement of it transmitted to the court of appeal, with the reasons assigned by the judge for the value affixed to every portion of it, will enable the appellate court to decide.

With regard to the third stage, the only com-

Jurispru-
dence
Jussieu.

plaint there can be is, that the judge has not taken measures to execute his own sentence. If any inquiry is in this case to be made, the proper course is, that the appellate court refer it to one of the neighbouring judges. When a simple act is to be done, the proper order is to be dispatched, and the proper penalties for non-performance exacted.

It thus appears, that for every thing which is required to be done by the appellate judicature, nothing whatsoever is required, as a foundation, but certain papers. The presence is not required, either of parties or of witnesses.

As it is of no great consequence, in a country in which the means of communication are tolerably provided, whether papers have to be transmitted 50 or 500 miles, the distance even though considerable, of the seat of the appellate jurisdiction is a matter of very little importance. The object, then, is to get the best seat—that is, the best public. The best public, generally speaking, is in the capital. The capital, then, is the proper seat of all appellate jurisdiction. And that there should be one judge, and one judge only, in each court of appeal, is proved by exactly the same reasons, as those which apply to the courts of primary jurisdiction.

The question how many courts there should be, as well of primary as of appellate jurisdiction, is to be determined by one thing, and one thing only; namely, the need there is for them. The number of the courts of primary jurisdiction must be determined, in some instances, by the number of suits; in some, by local extent. To render justice sufficiently accessible, the distance from the seat of judicature must not be great, though the number of accruing suits, either from the paucity or from the good conduct of the people, should be ever so small.

As the judgment seat should never be empty, for the need of staying injustice is not confined to times and seasons, and as one judge may be sometimes ill, sometimes called to a distance even by the duties of his office, provision ought to be made for supplying his place. For this purpose the proper expedient is a deputy. That the deputy should well perform his duty, the best security is, that he should be chosen and employed by the judge, the judge being

responsible for the acts of the deputy as his own. Whatever it is which the judge cannot do, or cannot conveniently do, in that he may employ his deputy. If there is a great influx of causes, the deputy may be employed in some of those the least complex and difficult. If there is any business, not of first rate importance, requiring the presence of the judge at a distance, the delegation of the deputy or deputies is the proper resource.

Besides the judge and his deputy, there are two adjuncts to every tribunal, which are of the utmost importance; indispensable, indeed, to the due administration of justice. These are a *pursuer-general* and a *defender-general*. The business of both pursuer-general and defender-general is to reclaim the execution of all laws in the execution of which the nation has a peculiar interest, though individuals may not. The peculiar business of the pursuer-general is to act on behalf of the administrative authority, in its character of plaintiff, and on behalf of every plaintiff who is without the means of engaging another advocate; to obviate any prejudice he sees likely to arise to justice from the conduct of plaintiffs, whether in civil matters or penal; and to perform in the case of all offences, where no private prosecutor appears, the office of prosecutor. The peculiar duty of the defender-general is to act on behalf of the administrative authority in its capacity of defendant, and on behalf of every defendant who has not the means of engaging another advocate, and to obviate any prejudice he sees likely to result to justice from want of skill or other causes on the part of a defendant who pleads his own cause, or on the part of him who pleads it for him.

The courts of appeal, though all seated in the metropolis, ought to be as numerous as the speedy hearing of all the appeals which come to them requires. The judges of appeal ought all to be chosen from the judges of primary jurisdiction, not only on account of the education and the experience received, but as a step of promotion, and a proper motive to acquire the requisite education, and to merit approbation in the inferior employment. There is the same propriety, and for the same reason, in choosing the judges of primary jurisdiction from the deputies.

Jurispru-
dence
Jussieu.

JUSSIEU (ANTOINE DE), M. D. Professor of Botany in the Royal Garden at Paris, and a member of the *Académie des Sciences*, was born at Lyons in 1686, and educated at Montpellier, where he received his degree of Doctor of Physic, being afterwards associated with the faculty of Paris.

Although much occupied in the practice of medicine in the capital, he was ardently devoted to the study of botany, having, in the early part of his life, visited Spain and the southern provinces of France in search of plants. When stationary at Paris, he communicated various essays to the Academy, which are printed in its *Mémoires*. These are chiefly botanical, illustrating the characters or the qualities of va-

rious exotics, at that period not well known; but he has given several papers also, on extraneous fossils, and a few other subjects of natural history. He finished the two *Appendices* to Tournefort's *Institutiones Rei Herbariæ*, and edited the *Icones* of Barrelier. He also published a historical account of the magnificent collection of drawings of plants of animals, originally begun under the auspices of Gaston Duke of Orleans, and continued down to the present times.

When Linnæus visited Paris in 1738, he, in a letter to Haller, mentioned this, the elder, Jussieu, as "much engaged in medical practice, well versed in the knowledge of the species of plants, though too prone to multiply them, and strictly confined to the

ideas and principles of Tournefort.' In one important point, however, which could hardly escape Linnaeus, and ought not to be forgotten, he emancipated himself from the errors of his master, for he perfectly understood, and fully admitted, the doctrine of the sexes of plants. A letter of his, completely explaining this phenomenon, on the most correct principles, is given by Bradley, in his *Philosophical Account of the Works of Nature*, p. 25-32.

He died of an apoplectic fit, at Paris, April 22, 1758, aged 72.

(J. J.)

JUSTIEU (BERNARD DE,) younger brother of the preceding, and like him a Physician, and a member of the *Académie des Sciences*, was still more devoted to the philosophical as well as practical study of botany, and ranks among the greatest names in that science, as having first attempted to form a system, according to the *natural affinities of plants*. He was born at Lyons in 1699, and appears to have accompanied, or followed, his brother to Paris, where he occupied, under him, the place of botanical demonstrator, in the *Jardin du Roi*, and at length succeeded him as Professor of Botany. If his communications to the Academy were less numerous than those of his brother, they were of a rather superior character. In one of them, published in the *Mémoires* of that body for 1742, he enters on the subject, then scarcely touched by any person, of the animal nature of certain marine productions, previously taken for plants; and we perceive in his inquiries, dawnings of that meridian light, which our countryman Ellis afterwards threw on these curious tribes. On other occasions he explained the flowers of the *Littorella*, and, with much acuteness, the more obscure fructification of the *Pilularia*. He wrote, in conjunction with the learned Comte de Caylus, on the *Papyrus*, and he gave an improved edition of Tournefort's *History of the Plants about Paris*, in 1725.

Linnaeus became personally acquainted with this ingenious man at Paris, in 1738, and maintained, for some years, an intimate correspondence with him. They could not be long in each other's company without discussing the natural affinities of plants, a study which seems to have been much advanced, if not first excited, in the mind of Linnaeus, by his correspondence with Haller. Bernard de Jussieu had, about the same time, by his own contemplations, probably, been led to consider it; for the system of Tournefort, in which he was educated, is too artificial in principle to have given him any such ideas. In its execution, indeed, that great author is led, by his own good sense, into some natural and philosophical views, in spite of his system; and these may possibly have caught the attention of Jussieu. However this may be, mutual satisfaction, and reciprocal instruction, could not but flow from the converse of Bernard de Jussieu and Linnaeus. They traced out together the characters and the limits of various natural assemblages, or orders. Every day produced, and every letter communicated, some new discovery. But as the multifarious hordes of the north appear originally to have used one common tongue, which, after they were dispersed, divided, and cultivated,

when it came to be written, assumed the form of various distinct languages, so these two botanical philosophers, when their more intimate intercourse had ceased, pursued different paths, and went far towards different conclusions. Linnaeus, after throwing the whole vegetable creation, more or less completely, into natural groupes, became more and more persuaded, that it was not only impracticable to connect them by one synoptic clue, or system, but that not one of his assemblages, or orders, was capable of precise and unexceptionable definition. On the other hand, Bernard de Jussieu, to the last, aimed at a general scheme of classification, though he accomplished little more than throwing his several orders into larger assemblages, and disposing the whole, as indeed Linnaeus himself has done, in one series, according to their relationship to each other. The French Botanist is recorded to have spoken with great diffidence of his own performance, and has written nothing of a general classification. But he often gave hints, in lectures or conversation, by which others perhaps have profited. This appears from the preface to the *Genera Plantarum* of his distinguished nephew, Antoine Laurent de Jussieu, the present Botanical Professor at Paris, who, following up the ideas of his uncle, and sacrificing something to technical convenience, at the expence of nature, has contrived to exhibit a tolerably natural system, founded on methodical principles.

It would be to little purpose to discuss, at the present day, the claims of Linnaeus or of Bernard de Jussieu to originality in the study of natural orders. Professor De Candolle has justly asserted, that they had the same object in view, and adopted, in the main, the same principles. B. de Jussieu, in a letter, dated February 15, 1742, congratulating Linnaeus on his appointment to the botanical chair at Upsal, says, "*Floræ devotus omnino poteris viam quam monstrasti facilem amplius aperire, naturalemque methodum tandem perficere, quam desiderant et expectant botanophylæ omnes.*" In a subsequent letter of May 7, 1746, he tells his Swedish friend, "*Scio quantum emolumentum receperint qui secundum tua principia student; memet experientia docuit.*" This is enough to settle the question, though great allowance is, perhaps, due to the modesty of Jussieu, who was less disposed to honour himself than his friend.

His biographer, the celebrated Marquis de Condorcet, records his singularly amiable and unaffected manners. These, during his occupation of arranging, according to natural classes, the garden of Trianon, attracted the notice and esteem of his sovereign, Louis XV. to whom any unsophisticated character, or object, could not but form an agreeable relaxation from the routine of a court. Jussieu obtained plants and seeds to be sent to his friend in the king's name. He pursued his innocent and useful studies till his death, which happened in 1777, in his 79th year.

A compendious view of his nephew's system, and a comparison of their Natural Orders with those of Linnaeus, may be seen under the article BOTANY, in the second volume of this *Supplement*. (J. J.)

Kaleido-
scope.History of
the Inven-
tion of the
Kaleido-
scope.

KALEIDOSCOPE, an optical instrument, invented by Dr Brewster, which, by a particular arrangement of mirrors, or reflecting surfaces, presents to the eye, placed in a certain position, symmetrical combinations of images, remarkable for their beauty and the infinite variations of which they are susceptible. The name is derived from the Greek words *καλός*, beautiful, *εἶδος*, a form or appearance, and *σκοπεῖν* to see.

The effect of combining two or more plane mirrors, so as to produce a multiplication of images, had long been known and described by writers on optics. Baptista Porta, in his *Magia Naturalis*, gives an account of the construction of an instrument, which he calls *polyphaton*, in which two rectangular specula are united by two of their sides, so that they may be opened or shut like a book, and the angles varied; and also of a polygonal speculum, consisting of several mirrors arranged in a polygon, for multiplying in different directions the images of objects. Kircher, also, in his *Ars Magna Lucis et Umbrae*, describes, as an invention of his own, the former of these constructions, and distinctly traces the relation between the angle of inclination of the mirrors, and the number of images formed. The very same contrivance was afterwards adopted by Bradley for the purpose of assisting in the designing of garden plots and fortifications; and he states that, "from the most trifling designs, we may, by this means, produce some thousands of good draughts." But the particular application of this principle in the case where the two reflectors are inclined to one another at a small angle, so as to form a series of symmetric images, distinctly visible only in a particular position of the eye, was a discovery reserved for Dr Brewster. The first idea of this remarkable property occurred to him in the course of some experiments in which he was engaged on the polarisation of light, during the year 1814. But the only circumstance which at that time attracted his attention, was the circular arrangement of the images of a candle round a centre, and the multiplication of the sectors formed by the extremities of the plates of glass, between which the light had undergone several successive reflections. In repeating, at a subsequent period, some experiments of Mr Biot on the action of homogeneous fluids upon polarised light, and in extending them to other fluids which he had not tried, Dr Brewster happened, for greater convenience, to place them in a triangular trough, formed by two plates of glass, cemented together by two of their sides, so as to form an acute angle. The ends being closed up with pieces of plate glass cemented to the other plates, the trough was fixed horizontally, for the reception of the fluids. The eye being necessarily placed without the trough, and at one end, some of the cement which had been pressed through between the plates at the object end of the trough, appeared to be arranged in a remarkably

regular and symmetrical manner. Pursuing the hint thus obtained, and investigating the subject optically, he discovered the leading principles of the kaleidoscope, in as far as the inclination of the reflectors, the position of the object, and that of the eye, were concerned. He then constructed an instrument in the simplest form, and showed it to some of the members of the Royal Society of Edinburgh, who were much struck with the beauty of its effects. Several very material improvements were subsequently made by the inventor in the construction and application of the instrument, for which he then took out a patent. But, in consequence of one of these instruments having found its way to London, its properties became generally known before any number of the patent kaleidoscopes could be prepared for sale. It very quickly became popular; and the sensation it excited in London throughout all ranks of people was astonishing. Kaleidoscopes were manufactured in immense numbers, and were sold as rapidly as they could be made. The instrument was in every body's hands, and people were every where seen, even at the corners of streets, looking through the kaleidoscope. It afforded delight to the poor as well as the rich: to the old as well as the young. Large cargoes of them were sent abroad, particularly to the East Indies. They very soon became known throughout Europe, and have been met with by travellers even in the most obscure and retired villages in Switzerland. Dr Brewster states, that no fewer than two hundred thousand kaleidoscopes were sold in London and Paris in the space of three months; "and yet," says he, "out of this immense number there is, perhaps, not one thousand constructed upon scientific principles, or capable of giving any thing like a correct idea of the power of the kaleidoscope; and of the millions who have witnessed its effects, there is perhaps not one hundred who have any idea of the principles upon which it is constructed, and of the mode in which those effects are produced." To convey a knowledge of these principles is the object of the present article.

It follows from the optical law of the equality of the angles of which the incident and reflected rays make with a line perpendicular to the reflecting surface at the point of incidence (see *Encyclopædia, Optics*, § 169, 172), that rays which diverge from any object and fall on a plane surface, will, after reflection, proceed in the same course as if they had immediately diverged from a point situated at the same distance behind the reflecting surface as the radiant point is before it. This point is called the *virtual focus* of those rays; and the eye receiving them will have the perception of a reversed image of the object in this situation. Thus the mirror AA' (Plate XCIII. fig. 1) will produce a reversed image of the object R, situated at the point S, in the line Rps, perpendicular to the surface of the mirror; and this image will appear in the same place what-

Kaleido-
scope.Optical prin-
ciples on
which it
acts.

Kaleido-
scope.

ever be the situation of the eye, as E, provided the reflected rays rE meet it.

Since the course of the reflected rays is the same as if they had immediately proceeded from a real object of S, where its image is seen, this image will, with relation to another mirror, have all the effect of a real object; and a second reflection of the rays by a new mirror at BB' , will produce, at the point T, equally distant from BB' as S is, but on the other side of it, an image of the first image, visible to the eye at E by the twice reflected rays $RqpE$. As the first image was reversed with respect to the object, so the second image will be reversed with respect to the first, and therefore direct when compared with the object. The second image may, it is evident, by a new reflection from the first mirror, give rise to a third, which will now again, like the first image, be reversed; and so on, in succession, may a series of images alternately reversed and direct, be produced on each side by two mirrors only, in consequence of multiplied reflections, provided the mirrors are of sufficient extent to admit of them, and provided the eye be so placed as to receive the rays which are last reflected.

If the mirrors be parallel to each other (see fig. 2,) the images of the intervening objects, $AA'BB'$, will be ranged in succession in a continued line on each side. If they be somewhat inclined to each other (as in fig. 3,) the images will be disposed in the arch of a circle, having for its centre the point in which the directions of the mirrors unite. If the mirrors be of sufficient length, or sufficiently inclined, so as actually to meet; and if, moreover, the angle they form be an even aliquot part of a circle, the images of all the objects situated in the space between them, ABC, fig. 4, will together occupy a circular field, and will be disposed in the form of sectors all round the circle.

General method of tracing the course of the Rays.

This circular arrangement of the images, however legitimately it may have been deduced from the simplest law of optics, appears to be so extraordinary an illusion of the sense, as to call for somewhat further examination before we can feel perfectly assured that it is a necessary consequence of that law. Perhaps the most satisfactory method of prosecuting their examination is to investigate separately the mode in which each of the images results from the successive reflections by the two mirrors. A very simple and convenient rule may be laid down for enabling us to trace the whole course, however complex, of the rays which form these images; and this rule will be best understood by considering, as an example, its application to one of the remote images in the circular field. Thus, in the circular field, AHL, fig. 5, divided into equal sectors by the radii CF, CG, CH, &c. let S be one of the remoter images of the object R, formed by four reflections from the mirrors AC, BC; and let E be the place of the eye. Draw the line ES, intersecting the radii already mentioned in P, Q, T, V; make Cq equal to CQ , and join Pq ; make Ct equal to CT , and join qt ; make Cv equal to CV , and join tv , and vR . Then $RvtqPE$ will be the real course of the rays, by which the image of R is seen at S by the eye at E; for it is sufficiently apparent, without the necessity

Kaleido-
scope.

of a formal demonstration, that by this construction, the equality of the angles of incidence and reflection is every where preserved. The different positions of the line PS, that is PQ , QT , TV , and VS , are in fact the images of Pq , qt , tv , and vR respectively, which are so many portions of the real course of the reflected rays. It is evident that a similar construction will, in every other case, furnish us with the actual course of all the rays from which images result, through all their successive stages of reflection; and it has also the advantage of giving us the exact angles of incidence and reflection throughout the whole path.

We have hitherto, for the sake of perspicuity, supposed both the object and the eye, together with the path of the rays, to be in the same plane. But it is obvious that the same method of construction and of reasoning may be employed in tracing their course, if we suppose the mirrors to be prolonged in a direction perpendicular to the plane of the figure, and the eye raised above that plane. The space between the mirrors, instead of being the sector of a circle merely, is now the sector of a cylinder; which cylinder may be completed by supplying the other sectors which compose it, as is represented in fig. 8, where $ACac$ and $BCbc$ being the mirrors, the rest of the cylindrical space is occupied by complementary sectors. The course of the rays by which the eye at E will see the image S, for instance, of the object R, may readily be traced by drawing a straight line from E to S, which will pass through as many planes $BCbc$, &c. as the rays have suffered reflections. The portions of the line ES, intercepted between these planes, may, as in the former case, be regarded as the images (either reversed or direct, as the case may be) of some portion of the actual path of the rays between the mirrors; A will occupy the same position with regard to the complementary sector it traverses, as the real path does in the original sector bounded by the mirrors. By drawing, in this sector, lines similarly situated with respect to its sides, at the several portions, PQ , QT , TS of the line ES, are with respect to the sides of their respective sectors, we obtain the real course of the rays, $RtqpE$.

Symmetry appears to be the principal constituent of beauty in the forms given to the various works of art which have exercised the skill and ingenuity of man; and the richness of each individual ornament, as well as the pleasing effect of the whole assemblage, is generally in proportion as this principle has received a more perfect development. Even nature, in the multitude of forms with which she has invested the different tribes of the animal creation, has, with but few exceptions, followed the law of symmetry, in as far as respects the perfect similarity of the two sides of the body. In almost all the higher classes, or those which are comprehended under the great division of vertebrated animals, and in many of the inferior tribes, as in insects, one half of the animal form is the reflected image of the other half. A still higher degree of beauty, derived from a more extended symmetry of form, has been displayed in the structure of objects in the vegetable kingdom. Flowers, in particular, derive a peculiar

Kaleidoscope.

beauty from their presenting to the eye a symmetrical combination of forms with reference to a common centre. This is also the general model followed in the structure of radiated animals, of which the star-fish and sea anemone are examples. In those works of art in which there is the greatest scope for the indulgence of fancy in the production of pleasing effects, the most perfect and successful kinds of ornament are those resulting from a symmetrical arrangement of parts, which is not confined to a single lateral repetition, but is extended in various directions in space, and is multiplied and alternated in different lines, and around different centres. It is the latter of these combinations, more especially, that is represented by the kaleidoscope, namely, the disposition of a certain number of pairs of images symmetrically disposed around one or more centres.

On examining the subject more minutely, we find that the first element of this symmetry consists in the union of any particular form, or of its direct image, with its reversed image, by which a new form is created, composed of two simple forms similar to each other, and similarly situated with respect to a given line. If a succession of these compound forms be now arranged around a centre, they will combine into a perfect whole, in which all the similar parts are brought into union, and which must thus afford pleasure, by enabling the mind readily to take in and comprehend every part at a single glance. The operation of the kaleidoscope is, in this way, to create regularity and symmetry out of every form that is presented to it, however irregular in itself that form may be. Thus, out of the few simple lines contained in fig. 9, the appearance presented in fig. 6 is created by the instrument. It is scarcely necessary to observe, that the original lines, which occupy the sector between the mirrors, are seen by direct vision, and that their appearance unites itself on each side with their images seen by reflection. We shall in future designate the whole of the appearance thus produced by the kaleidoscope, by the term *Spectrum*.

Appearances
of polygons,
stars, curves,
&c.

If we examine the effect produced by each elementary portion of the compound figure of the spectrum, we shall find that any straight line reaching directly across the sector, as *fg* (fig. 9), is formed by the kaleidoscope into a regular polygon, having as many sides as the numbers into which the circular field is divided: if it be at right angles to either of the sides, the polygon will have only half the number of sides. A line, as *mn*, crossing the field between the mirrors in an oblique direction, is converted by the instrument into a polygon of the same number of sides as the former, but with salient and re-entering angles; that is, into the form of a star, with a number of rays equal to half the number of sectors. Another line crossing the field in an opposite direction, gives another star, having its rays intermediate to those of the former. Curved lines form by their union a multitude of beautiful and elegant figures, of which the variety is inexhaustible. Each group, taken separately, possesses its peculiar and intrinsic beauty; but the effect of the whole assemblage is considerably heightened by the combi-

nation, and by the regularity of the relations that each part bears to all the others.

Kaleidoscope.

Having thus given an account of the general principles upon which the kaleidoscope is constructed, and of the mode in which it acts, we are now prepared to direct our attention to the conditions which are required for the perfect performance of its functions.

Require conditions.

If the mirrors of the kaleidoscope could reflect the whole of the light which falls upon them, the images would possess the same degree of brilliancy as the objects from which they are derived; and their number would be limited only by the more or less favourable position of the mirrors, and of the eye with relation to the objects. But as a very large portion of the incident light is, in most cases, destroyed by reflection, it follows that each successive image will be fainter than that which preceded it; and that in the progress of the reflections we must very soon arrive at a limit beyond which they become no longer visible. It is found, from experiment, that the quantity of light lost by reflection is in all cases greatest when the rays fall perpendicularly on the mirror, and least when they fall with the greatest obliquity. The difference is more considerable in the case of glass, than in that of metallic surfaces. Thus, in a common looking-glass, the images of objects seen by holding it directly opposite to them, are produced wholly by the surface of the quicksilver, those reflected by the glass being too faint to occasion any interference. If the glass be placed obliquely, so that the angles of incidence and reflection be large, a greater proportion of light will be reflected from the glass, and the images formed by it will be bright enough to be seen, and will mix themselves with the images from the quicksilver. At a certain angle, both sets of images will appear of equal brightness; and by still further increasing the obliquity, those produced by the quicksilver will gradually fade away, and vanish, leaving the images produced by the glass perfectly distinct, and nearly as brilliant as the objects themselves.

The following table, abridged from one given by Dr Brewster, and founded on the experiments of Bouguer, shows the number of rays reflected from plate glass at various angles of incidence, the number of incident rays being supposed to be 1000.

Complement of the angles of incidence.	Rays reflected out of 1000.	Complement of the angles of incidence.	Rays reflected out of 1000.
2½°	584	30	112
5	543	35	79
7½	474	40	57
10	412	50	34
12½	356	60	27
15	299	70	25
20	222	80	25
25	157	90	25

With the help of this table, and the method above explained of tracing the course of the rays, and on investigating the angles of incidence, the degree of illumination of any part of the spectrum might be

Kaleidoscope.

calculated, were it not for a new condition, termed *polarisation*, with which the rays of light are affected by reflection, and which may also contribute to the further loss of light, when the reflection is repeated at certain angles, and in certain positions of the plane in which it takes place: a circumstance which is not without its influence in the case of the kaleidoscope, especially in those constructed with glass mirrors.

As the effect which the kaleidoscope is intended to produce is to be the result of repeated reflections, it is an object of essential importance, in order that as little light may be lost as possible, that all these reflections should take place with the greatest obliquity. With this view, the mirrors should be of considerable length, and the eye should be raised above the field of view, and brought as near as possible to the planes of the mirrors; that is, as near as possible to the remote end of the line of their intersection. From this situation the remoter sectors will be seen by a greater quantity of light than from any other; and consequently the illumination of the spectrum will be more equal in every part. This position of the eye affords the further advantage of giving to the spectrum a circular appearance: for it is obvious, that if viewed from any other and more oblique situation, it would, from the laws of perspective, appear more or less elliptical. It is scarcely necessary to remark, that the eye cannot be mathematically in the line of junction of the mirrors, for no light would in that case reach it by reflection from them.

Proper Form of the Mirrors.

The essential parts of the kaleidoscope, then, are the two mirrors ACE, and BCF, (fig. 10), which should be from six to ten inches in length, and from one inch to an inch and a half in breadth at the object end C; while they are made narrower at the other end, E. They are kept apart at their upper edges, and united along their lower edges CF, so as to form an angle which must be an even aliquot part of a circle. The angles 36° , 30° , $25^\circ\frac{1}{2}$, $22^\circ\frac{1}{2}$, 20° , or 18° , which divide the circumference of the circle respectively into 10, 12, 14, 16, 18, and 20 equal parts, are the only angles which can conveniently be employed with glass mirrors. The objects to be viewed must occupy the space ABC, between the ends of the mirrors, and must be situated in the plane formed by these lines. They are to be viewed from the opposite, or narrow end, *e*; the eye being placed near to the angular point, F, formed by the junction of the ends of the mirrors. It should, however, be a little above this point, in order that a sufficient quantity of light may enter through the pupil. By trial, the proper distance at which the maximum of illumination is obtained will easily be found.

Accuracy in their Junction.

It is of considerable importance that the junction of the mirrors be a perfectly straight line, free from roughness, and from particle of dust. Any irregularity in this line will interfere with the perfection of the image at that part most remote from the object. The projection of this line of junction of the mirrors on the field of view is a line CD, fig. 4, immediately opposite to the middle of the space between the mirrors. If tolerable pains have been taken to apply a straight and smooth edge of one mirror upon the

surface of the other, and to preserve them clean, this line will scarcely be seen, more especially as the greater part of it is placed much nearer than the objects contemplated, and lies, therefore, within the distance to which the refractive powers of the eye are adapted; it is, therefore, seen only indistinctly.

Kaleidoscope.

Any deviation in the angle formed by the mirrors from that which accurately divides the circle into an even number of sectors, is quickly perceived by the eye, from the consequent irregularity which takes place in the compound figure of the spectrum at the part most remote from the object. This is illustrated by fig. 7, where the last ray of the star is seen to be imperfect, from the want of correspondence in the images which meet in the remote sector. If the angle be too small, the image is redundant, from a reduplication of one portion; if too large, the image presents a deficiency. But, in consequence of the aperture of the pupil being of sufficient size to admit portions of the images from both mirrors, reflected from the parts immediately adjacent to the line of their junction, these two images will be, for a certain space, seen in the same direction, and will consequently overlap and interfere with each other. As soon as the angle of the mirrors is rendered correct, the double images coalesce into one, and perfect symmetry is restored to the spectrum. It is necessary to observe, that the angle must be an even aliquot part of a circle; that is, must divide it into an even number of equal parts. If the division were into an odd number of parts, as in fig. 7, the discordance of the adjacent images at the remote sectors would be the greatest possible. This will appear from considering that the images in the successive sectors on each side, being alternately reversed and direct, those in the sectors immediately adjacent to the radius most remote from the mirrors, would both be of the same kind; the one, therefore, could not be the reverse of the other, a relation which, as we have already seen, is the elementary condition of symmetry in each pair of images. The corresponding parts of each, indeed, instead of being adjacent, would then be the most remote from one another. This circumstance, namely, the necessity of the angle of the mirrors being the even aliquot part of a circle, although it be an essential condition of the instrument, is not mentioned in the specification of Dr Brewster's patent. It was first noticed by the author of this article, in the *Annals of Philosophy*.

If we investigate the proportion of light distributed over the field of view, by considering the degrees of the obliquity with which the rays infringe upon the mirrors, and also the number of reflections which they sustain, we shall find that it diminishes nearly in the same proportion as we recede from the edge of the sector bounded by the mirrors, and is least in the remotest sector. The line of equal illumination in each individual sector, or the *isophotal* line, as Dr Brewster has termed it, is parallel to that radius of the sector which is nearest to the mirror on that side. It follows as a consequence, that the light will diminish in each sector in proportion as we recede from the angular point, or common centre of the field. This last circumstance limits us to the magnitude which it would be proper to allow to the field

Dimensions of the Mirror.

Kaleido-
scope.

of view, and therefore restricts us, in the breadth of the mirrors, when they are of a given length. In general, their breadth should not exceed one-sixth of their length, and the angle subtended by the circular field will then be about 19° . The proper proportion, however, varies according to the angle at which the mirrors are inclined. The larger this angle, the greater latitude may be allowed in extending the field of view; while, if the angle be small, the number of reflections for completing the remote parts of the spectrum will be great; the light will become too faint to allow the eye to distinguish the parts at the circumference; and the diameter of the field must be contracted by lessening the breadth of the mirrors.

What has now been said relates only to the proportional length and breadth of the mirrors. With regard to their absolute size, we must be guided in our choice by other circumstances of convenience. As the length of the instrument determines the distance of the eye from the field, it should be such as to admit of the distinct vision of every part of the spectrum. This may be effected, if requisite, by interposing a convex lens of the proper focal distance, between the eye and the narrow end of the mirrors.

Position of
the Objects

The last circumstance we shall notice as essential to the perfect operation of the instrument, is, that the objects must be situated as nearly as possible in the plane ABC, fig. 10, formed by the ends of the mirrors. All deviations from this position are productive of irregularity in the spectrum. If the eye, indeed, were a mere mathematical point, and were it possible for it to receive the rays while placed at the very point of the angle E, the distance of the object from the mirrors would, in strictness, produce no deviation from symmetry. Let the plane MN be taken at a little distance from the ends of the mirrors, and the planes of the mirrors produced till they meet it in the lines *ac* and *bc*. It is evident that the space comprehended between these lines, is the only situation in that plane from whence rays can proceed so as to fall upon the mirrors; no object, therefore, which is not within that space, can have its image formed by reflection from the mirrors. The lines *ac* and *bc* are the projections of AC and BC, as viewed from the point E. But if the eye be raised to *e*, it will be apparent that a space below the former, and bounded by the lines *de* and *fe*, which will now be the projections of AC and BC, will come into view. The objects situated in this space will have no corresponding images, and their introduction into the field of view will produce confusion in every part of the spectrum. The magnitude of this additional space, measured by the interval *ce*, which is unrepresented by the instrument, and which may be termed the *aberration*, is dependant upon and proportional to two separate causes, namely, the distance of the eye from the angular point, and the distance of the object from the mirrors. The deviation from regularity which it produces in the spectrum increases as the object approaches to the centre. An eye accustomed to observe and admire the symmetry of the combined images, will instantly perceive it to be violated, even when the distance of the object, Cc, is less than the twentieth part of an inch. When the object is very distant, the defect of sym-

Kaleido-
scope.

metry is so enormous, that, although the object is seen by direct vision, and also in some of the sectors, it is entirely invisible in the rest. If the object, on the other hand, be placed within the reflectors, a symmetrical spectrum will, indeed, be formed; but the centre of this spectrum will not coincide with the centre of the circular field of view, and its effect in producing a symmetrical picture is thereby entirely destroyed. In order to ensure perfect mathematical symmetry, the objects should, strictly speaking, be limited to lines lying in the same plane, which plane must be exactly in contact with the ends of the mirrors.

We have hitherto considered the effects resulting from the combination of only two mirrors, in which case, the field of view is necessarily limited to a circle. But, on the very same principles, we may, by employing a greater number of mirrors, obtain an extension of this field in all directions, and produce groups of images around several centres, which shall be repeated in perpetual succession on every side. Kaleidoscopes of this description have, on that account, been called *Polycentral*, and, when properly constructed, their effects are exceedingly beautiful. With respect, also, to their utility, as applicable to the arts, they very far excel the simple kaleidoscope, inasmuch as the occasions requiring an ornamental design for a flat extended surface, are of much more ordinary occurrence than those in which we are limited to a circular space. The principles upon which polycentral kaleidoscopes should be constructed, and the conditions to which they are limited, were first pointed out by the author of this article, in the *Annals of Philosophy*, Vol. XI. p. 375, soon after the common instrument became known in London.

Polycentral
Kaleido-
scopes.

It is evident, that, by joining together a number of mirrors, so as to compose the sides of a prism, we might obtain a succession of images in every possible direction. But we must recollect, that for the production of symmetrical combinations of images, we are restricted in our choice of a base for the required prism to such angles only as will divide the circle into an even number of aliquot parts. This condition confines us to a very limited range. It excludes, in the first place, all angles above 90° ; and, therefore, all polygons having more than four sides. Of four-sided polygons, the square and the rectangle, where all the angles are right-angles, are the only figures that can give symmetrical combinations. After these, there remain only triangles; and among all the possible varieties of triangles, we can take only such as are formed with angles of 90° , 60° , 45° , or 30° , which are the quotients of 360° , divided by 4, 6, 8, and 12; all the other even aliquot parts of the circle being excluded by the necessary condition that the sum of those angles must be equal to 180° . We are, therefore, limited to the three following species of triangles, represented in figures 15, 16, and 17:

The first having all its angles equal to 60° , 60° , and 60° .
The second its angles respectively equal to 90° , 45° , and 45° ;
And the third its angle respectively equal to 90° , 60° , and 30° .
The sum of these angles, in each case, being 180° .

Only four
species ad-
mitted of.

Kaleido-
scope.Comparative
effects of the

Let us now inquire into the effects resulting from each of these combinations.

The comparative effects of these four species of polycentral kaleidoscopes are illustrated by figures 14, 15, 16, and 17, where A, in each case, represents the sections of the mirrors, or the base of each prism; B, the elements of each pattern; and C, the pattern itself, resulting from the series of reflected images.

Square Ka-
leidoscope,

It will be seen that the square polycentral kaleidoscope, fig. 14, produces a less pleasing effect than the others, because the attention being more particularly directed to the repetition of the same set of images in one direction only, the whole pattern appears composed of an alternation of longitudinal stripes. The direction of the stripes is determined by the general direction of the lines, in the elementary pattern approaching more to one of the sides of the base, than to the other side. It is scarcely necessary to observe, that the spectrum produced by a rectangular is quite similar to that of a square kaleidoscope, only that it is more extended in one direction.

Triascope,

The first of the triangular polycentral kaleidoscopes (fig. 15), which has for the base of its prism an equilateral triangle, affords very regular combinations of images, disposed in three different directions, which cross each other at angles of 60° and 120° ; thus presenting what may be called a triangular symmetry. The circumstance of each pair of images being combined in groups of three together in every part of the spectrum, has suggested the name of *Triascope* for this species of triangular polycentral kaleidoscope.

Tetrascope,

The second species of triangle (fig. 16), which may be made the base of the prism, is that composed of two contiguous sides, together with the connecting diagonal of a square; or, in other words, of a right-angled isosceles triangle. The result of this construction is to produce a division of the field of view into regular square compartments, having the base of the above mentioned triangle for their sides. The very perfect symmetry which results from this construction is the source of remarkably beautiful designs; the predominant character of which is an arrangement of forms grouped together by fours at a time, and symmetrically disposed in squares. Such an instrument may, on this account, be called a *Tetrascope*.

and Hexa-
scope.

The last species of triangular polycentric kaleidoscope, or that which takes for its base the half of an equilateral triangle (fig. 17), resulting from its division by a perpendicular drawn from an angle to the opposite side, affords also appearances of very considerable beauty. Here the predominant form is the hexagon, from the circumstance that the smallest of the angles, which is that of 30° , producing the greatest number of repetitions of the same image around one centre, the symmetry is most conspicuous with reference to that centre, and the attention of the spectator is immediately directed to the hexagonal compartments into which the field is thereby divided. As the pairs of images in these leading objects (such as the stars in the figure, which, it will be observed, have each six rays) are six in number, we shall, fol-

lowing the analogy of the other names, denominate this variety of the instrument a *Hexascope*. These names, derived from the circumstance which gives the chief character of symmetry to the extended spectrum, will perhaps be considered as sufficiently appropriate. They will, at all events, recommend themselves by their brevity, when we consider the very compound epithets which would otherwise be required in order to designate correctly the equiangular, triangular, polycentral kaleidoscope; the rectangular, isosceles, triangular, polycentral kaleidoscope; and the semi, equilateral, triangular, polycentral kaleidoscope.

Kaleido-
scope.

As a plane surface of indefinite extent admits of subdivision, by regular polygons of the same kind, only in three ways, namely, by triangles, by squares, and by hexagons, so each of these modes of division is the result of a separate arrangement of three plane mirrors, namely, that of the triascope, the tetrascope, and the hexascope. Of these, the two last appear to be those more especially calculated to afford assistance to artists in the invention of ornamental patterns.

It is evident, that the principal advantage which the polycentral kaleidoscopes have over the simple ones, is the greater extension they give to the field of view. This field might, in theory, appear to be infinite; but in practice it soon becomes limited, from the great loss of light attendant on repeated reflections. The effects of polarisation, in further diminishing the light, is also greater in them than in the simple kaleidoscope. On both these accounts, metallic are preferable to glass mirrors for their construction. The number of reflections required, in order to obtain any extent of spectrum, being greater than in the ordinary kinds of simple kaleidoscopes, the instrument must be of greater length comparatively with the breadth of the mirrors, as in this way the course of the rays will be more oblique with respect to the mirrors, and a larger portion of light will reach the eye. A greater obliquity is also obtained, with the same proportion between the length and breadth of the mirrors, by making them taper at the end next the eye. The instrument will then, see fig. 18, have the form of a truncated pyramid, instead of a prism; ABC being the triangular base, to which the objects are to be applied, and abc the narrower end at which the eye is applied. It is true, that, in mathematical strictness, this construction is incorrect; for the mirrors, in that case, having necessarily a degree of inclination to the base, the spectrum will be composed of portions, not of a plane, but of a spherical surface, which does not admit of the same divisions; but the field really visible to the eye is too limited to render this inaccuracy of any consequence.

After the detailed explanation which has been given, of the principles on which kaleidoscopes act, it will not be necessary to enter into any minute account of the methods of constructing them. A few practical directions may, however, be useful for the guidance of such as wish to provide themselves with this source of innocent amusement. In order to construct the simple kaleidoscope, two slips of plate-glass, about six or eight inches long, and about an

Construc-
tion of the
Simple Ka-
leidoscope.

Kaleido-
scope.

inch, or an inch and a half in breadth, must be procured. The best form for these plates is that represented in fig. 10, where one end of them is only half the breadth of the other. The newest plate glass should be employed, as that which is old has frequently scratches and imperfections on its surface, which occasion a great loss of light. They should have been skilfully cut with a diamond, so that at least one of the edges may be perfectly smooth, and free from chips. If this be not the case, one of the edges must be made quite straight, and freed from all imperfections, by grinding it with very fine emery upon a flat surface, such as another piece of plate-glass. The posterior surfaces of each of the plates are now to be covered with a black varnish, or with black sealing wax, so as to remove its reflective power. When this has been done, and the varnish is dry, take the plate of which the edge has been rendered perfect, and apply this edge against the surface of the other plate, as near as convenient to the edge of this latter plate, and keep the edges so applied in contact, by means of a strip of black silk or cloth glued along the back of the plates, so as to serve the purpose of a hinge, allowing of their opening and closing to a certain extent, like the leaves of a book. They are now to be adjusted to the proper angle, which may be done with the greatest accuracy, by directing the mirrors, placed as in fig. 10, to any line, or the straight edge of any object in contact with the broad ends, and very obliquely situated with respect to the edge of either of the mirrors; then looking from the other end, open or shut the plates till the figure of a star appears, having 6, 7, 8, or any other number of rays which may be thought desirable, and observing that the images of the rays in the spectrum most remote from the object perfectly coalesce. The mirrors must now be fixed in their position by small arches of wood or brass, extending across the open ends of the plates AB in two or three places. These may at first be attached temporarily by means of sealing-wax; but they should afterwards be fastened more securely by other pieces glued to the plates in several places along the edges *Ac*, *Bc*. The clearness of the effect of the instrument is much promoted by excluding all light, except what comes from the field of view; and this is best accomplished, by laying a strip of black velvet, previous to the fixing of the pieces just described, all along the upper side of the instrument, so as to line the whole of the space between the upper edges of the mirrors. All reflection of light from that quarter is thus effectually precluded.

The plates thus prepared are to be placed in a tube, as represented in fig. 11, so that the broad ends of the mirrors shall barely project beyond the end of the tube; while the narrow end is placed so that the angle formed by the junction of the mirrors, shall be a little below the middle of that end of the tube. The plates must then be kept in this position by pieces of cork or wood, wedged in between them and the tube; taking care, however, that they press but lightly on the mirrors, for a very slight force is capable of bending and altering the figure, even of very thick plates of glass. A cover, with a circular aperture in the centre, is then to be fitted to the end

abc, which should, in general, be furnished with a convex lens, whose focal length is an inch or two greater than the length of the mirrors, in order to allow the eye to see every part of the spectrum with perfect distinctness. Persons who are short-sighted will of course not require this lens; but it will still be expedient to close the end *abc* of the mirrors, with a piece of plane glass, as a security against the introduction of dust.

In constructing polycentral kaleidoscopes, where three mirrors are employed, the third mirror occupies the place of the black velvet and connecting pieces already described. Great care should be taken to have three very perfect edges for the junctions of the plates with each other; and considerable attention should be paid to their being fixed at the exact angles required by the construction; and when once placed correctly, they are to be retained in their relative position by effectual securities. Similar remarks apply to the construction of square and rectangular polycentral kaleidoscopes.

The instrument, when so far completed, is now ready to be applied to the objects which are to form the spectrum. A case for holding these objects, and for communicating to them a revolving motion, is fitted to the object end of the tube: the best construction for such a case is the following. Upon the end of the tube *abcd*, fig. 12, (corresponding to the end of the mirrors *ABC*, fig. 11), is placed a ring of brass, *mn*, which moves easily upon the tube, and is kept in its place by a shoulder of brass on each side of it. A brass cell, *MN*, is then made to slip tightly upon the moveable ring *mn*, so that when the cell is turned round by means of the milled end at *MN*, the ring *mn* may move freely upon the tube. The objects are to be placed in a small box, consisting of two glasses, one transparent, and the other ground, kept at the distance of one-eighth or one-tenth of an inch by a brass rim. This brass rim should consist of two pieces which screw into one another, so that the box can be opened by unscrewing it, and the objects changed at pleasure. This object box is placed at the bottom of the cell *MN*, as shown at *OP*; and the depth of the cell is such as to allow the side *O* to touch the end of the mirrors, when the cell is slipped upon the ring *mn*. The instrument when used, is to be held in one hand, with the angular point *E* downwards, and the cell is turned round with the other, so as to present the objects in succession before the aperture *ACB*, fig. 11.

The objects best fitted for producing pleasing effects, are small fragments of coloured glass, of sufficient size to occupy a certain portion of the interval between the mirrors, but not so large as to engross the greater part, or to interfere with each others motions, as they are made to fall in succession into the field of view, by the revolution of the case which holds them. Wires of glass, both spun and twisted, and of different colours, and shades of colours, and of various shapes, both curvilinear and angular, may be intermixed with the larger masses of coloured glass, together with one or two beads, bugles, fine needles, bent metallic wires, small pieces of lacc, and fragments of fine sea-weed. Looped curves like the figure 8, double curves like the letter S, or the

proper Ob-
jects.

Kaleidoscope.

figure 3, circles, ovals, spirals, triangles, or lines bent into angles, like the letter W or Z, have generally a good effect, either alone, or in combination with other objects. Care should, however, be taken not to crowd the case with too many objects at a time, as an excess in this respect produces a degree of complexity totally inconsistent with beauty. In order to obtain a greater variety in the styles of patterns produced, a number of different cases, with objects may be provided, so as to fit on occasionally, and be changed at pleasure.

Telescopic or Compound Kaleidoscope.

By Dr Brewster's very ingenious contrivance of substituting for the case of objects above described, and which is applied in contact with the ends of the mirrors, a convex lens placed at a certain distance from them, the images of distant objects may be brought to occupy the exact place adapted for their reflection by the kaleidoscope, and may thus afford a still greater variety of symmetric combinations. This operation of the lens is illustrated by fig. 13, where the lens L forms an image of the object R at F, the space between the ends of mirrors, which image is multiplied by the reflecting powers of the instrument, and forms a symmetric spectrum, precisely in the same way as if a real object of that size had occupied its place. The lens may be fitted to the end of a separate tube, external to that of the instrument, and capable of being drawn out upon it to the proper distance, which is known by observing when the spectrum appears perfectly symmetrical. The instrument in this form has been called the *Telescopic or Compound Kaleidoscope*; and is applicable to distant objects of every description, and equally so to those in motion, as to those at rest. All their movements are represented with singular effect in the spectrum. A blazing fire viewed by it, gives the appearance of beautiful fireworks, at one time rushing with great rapidity towards the centre, and at another issuing from it towards the circumference, or darting in splendid stariform corruscations over the field of vision. These varieties in the spectrum are occasioned both by turning the instrument round its axis, and by moving it forwards in any direction.

The compound kaleidoscope has thus a much more extended range than the simple kind; and it has this further advantage, that it admits of the symmetry of the spectrum being rendered perfectly correct, since the images may be brought exactly to the ends of the mirrors; a condition which can never be completely obtained, when the objects are confined in a glass case, as they must then always be separated from the mirrors by at least the thickness of the glass.

The focal length of the lens should always be much less than the length of the outer tube, and should in general be such as to be capable of forming an image at the end of the mirrors, when the object is four or five inches from the lens. Its diameter should be such as that, when it is at its greatest distance from the mirrors, it shall still occupy the whole of the field of view which is seen by direct vision; or, in other words, that the eye shall not see any part of its edge.

Its application to the Magic Lantern, &c.

The exhibition of the effects of the kaleidoscope to a number of spectators at the same time, by throwing the images on a wall, after the manner of the

magic lantern, or solar microscope, might be easily accomplished, if sufficient light could be procured for the illumination of the objects. The form of an instrument for this purpose, is represented in fig. 20, where L is the lamp, the light from which being augmented by the reflector M, and concentrated by the very convex lens N, upon the transparent objects at the end of the kaleidoscope K, is formed into an image on the opposite wall by refraction through the lens P, the focal distance of which is somewhat shorter than the length of the tube. The brilliant light produced during combustion, carried on by means of a stream of oxygen gas, is peculiarly fitted for the exhibition of these effects, as was very successfully shown by Mr William Allan, in his lectures at Guy's Hospital, London.

By a contrivance on a similar principle, the patterns formed by the kaleidoscope may be copied, if thought necessary, by receiving them in a camera obscura. The readiest mode of tracing them, however, is by the use of a camera lucida, applied to the instrument at the end next the eye. The kaleidoscope might also be applied to the microscope, if it were worth while to multiply these applications, for which, however, considering the infinite variety of designs which the simpler instruments afford, there appears not to be the least necessity.

Instead of employing the exterior surfaces of glass as the reflectors, we may employ the interior surfaces of a prism of solid glass for that same purpose; and we may obtain in this way, as was shown by Dr Brewster, a total, instead of a partial reflection of light. This solid form of the instrument is peculiarly fitted for polycentric kaleidoscopes; but it is liable to the objection of its being extremely difficult to procure a piece of glass of sufficient size entirely free from veins, and also to obtain the perfect junction of the two reflecting planes.

Simple kaleidoscopes have been variously constructed with reference to the angles of inclination of the mirrors. In some instruments, called by Dr Brewster *Polyangular Kaleidoscopes*, this angle may be varied at pleasure, by allowing the mirrors to move on their connecting edges as on a hinge, so as to open or close at pleasure by means of a screw. Others admit of the mirrors entirely separating, so as gradually to become parallel to each other, and thus give rectilinear or annular patterns, as is seen in figures 2 and 3. But there is no occasion to dwell more particularly on these subjects, as the circumstances of their construction and effects must be sufficiently obvious from what has been already said; and there is probably more ingenuity than utility in devising these variations. We shall therefore conclude, by merely noticing a convenient mode of uniting several of these instruments, which was suggested by the author of this article, with a view to compare the effects of the simple and polycentric kaleidoscopes, applied to the very same set of objects. Fig. 20 shows a section of that instrument, in which *mn* are the mirrors of a simple kaleidoscope in the middle of the tube *t*, and which might be set to any angle; the mirrors *def* on one side forming a tetrascopes, and *pqr* on the other, a hexascopes. The whole was enclosed in the tube *t*, at the eye end of which were

Kaleidoscope.

Kaleido-
scope
H
Kant.

three separate apertures, in order to allow the observer to look through each in succession. The other end was fitted with a case of moveable objects, as in fig. 12; and was also provided with an additional tube for the reception of a lens instead of the case, and capable of being drawn out, so as to convert the whole into a telescopic instrument. The effect of the whole combination was very striking.

See Dr Brewster's *Treatise on the Kaleidoscope*, Edin. 1819. Harris's *Treatise on Optics*. Wood's *Optics*. Dr Roget on the *Kaleidoscope*, in the *Annals of Philosophy*, Vol. XI. p. 375; and the *Compte rendu des Travaux de l'Académie de Dijon*, pour 1818, p. 108-117. (w.)

KANT (IMMANUEL), a very eminent metaphysician, and the author of that theory which has been distinguished by the name of the *Critical*, or *Transcendental Philosophy*, was born at Koningsberg, in Prussia, on the 22d of April 1724. Of his paternal ancestors little is known with certainty; but tradition represents them, as having sprung from an emigrant Scotsman, of the name of Cant; and the philosopher himself, who frequently alluded to this traditionary extraction, is said to have been the first of his family who changed the initial letter of his name to K, with a view to adapt it to the German pronunciation.

The father of Kant, who exercised the humble profession of a saddler, or harness-maker, in the suburbs of Koningsberg, was distinguished rather for his integrity and respectability, than for his wealth. His mother appears to have been a woman of considerable talents, and of a more decided character. She was exceedingly pious, and much attached to the strict religious tenets and discipline of Dr Schultz; a divine who, at that period, enjoyed an high reputation for learning, eloquence, and piety.* Kant uniformly spoke of both his parents, but especially of his mother, with feelings of the warmest affection.†

Although far from being in affluent circumstances, his parents resolved to bestow upon their son, Immanuel, every advantage that could result from a liberal education. Accordingly, after having been taught to read and write at the charity school of the suburbs, he was sent, in the year 1732, to the *Collegium Fridericianum*, at the suggestion, it is believed, of Dr Schultz; who, even at that early period, had the penetration to discover the talents of the boy. At this school, he contracted an intimate friendship with Ruhnkenius, afterwards so celebrated for his philological attainments, which was maintained by occasional correspondence during the remainder of their lives, and which, in their early years, may naturally be supposed to have had a salutary influence on the studies of both. They were both

indefatigable students; and they not only mutually assisted each other in their school exercises, but read together, during their leisure hours, whatever books their inclination led them to peruse, or their circumstances permitted them to purchase. It is rather a remarkable circumstance, however, that, at this early period, Kant devoted his attention principally to philological studies; while his friend, Ruhnkenius, seemed to be attracted, by an apparently natural tendency of disposition, to the cultivation of philosophy. In their maturer years, as is well known, these early predilections were precisely reversed.‡

Having completed his preliminary education, he repaired, in the year 1740, to the university of his native town, where he applied himself, with great ardour, to the study of the mathematical, philosophical, and theological sciences. Among the professors of Koningsberg, several of whom were men of considerable talents and attainments, he appears to have attached himself particularly to Professor Martin Knutzen, well known, at that period, as the author of several useful works, to whose instructions in mathematics and philosophy Kant acknowledged himself to have been greatly indebted.§ To the great diligence and success with which he prosecuted his studies, at this period, his early writings bear ample testimony. The youth who, at the age of twenty-two, could boldly and successfully impugn the doctrines of Leibnitz and Wolf, and skilfully wield the weapons of dialectics against the authority of the most eminent metaphysicians of his day, must have bestowed no common pains in the acquisition of scientific knowledge, and in cultivating the powers of his understanding. From the earliest period of his career, too, he was left almost entirely to the resources of his own talents and prudence, and compelled, at every step, to struggle against the depressing influence of poverty. When scarcely arrived at manhood, he had the misfortune to lose both his parents, who had not the satisfaction of living to witness the fruits of their son's talents and industry. They, indeed, had never been able to afford him much pecuniary assistance; but he was fortunate in meeting with some relations of his family, who were in more affluent circumstances, and by whose liberality, combined with his own exertions and economy, he was enabled to continue the prosecution of his studies.

After a residence of about three years at the university, he acted in the capacity of a private tutor in several families, and lived about nine years with the Count de Hüllesen at Arnsdorf. During this period, he embraced the opportunities which his retirement afforded him, of collecting a vast store of general

Kant.

* He was Professor of Theology at the University of Koningsberg, and the author of several works which were much esteemed in their day: among others, of a work on the *Elements of Metaphysical Science*. ●

† Kant had several sisters, and an only brother, several years younger than himself, who took orders, and had a living in Courland, where he continued to reside until his death.

‡ Throughout every period of his life, however, Kant retained a great fondness for classical literature. He was particularly partial to the study of the Roman writers; and, even in his old age, he delighted to have an opportunity of reciting and applying passages from the works of his favourite authors.

§ Knutzen died in the year 1756, as extraordinary Professor of Philosophy at Koningsberg.

Kant.

knowledge in almost every department of science and literature, and of sketching the outlines of several of those philosophical treatises, which were soon afterwards published in rapid succession.

It is rather unfortunate that no record seems to have been preserved of the course of his studies during this most interesting period of his life; nor has he himself, so far as we know, left any memorials which might enable us to trace the gradual progress of his mind in the acquisition of knowledge. It is certain, however, that he both read and thought much. According to his own confession, he was not particularly well qualified to discharge the duties of a tutor; being always too deeply engaged in acquiring and digesting knowledge in his own mind, to be capable of communicating the rudiments of it to others. His mind seems to have originally entertained a strong bias towards mathematical and physical researches, and he exhibited some specimens of knowledge, acuteness, and originality of investigation in the latter branch of science, from which much eminence might have resulted, had his views been exclusively confined to that department.

It was probably during the period of his retirement at Arnoldsdorf, that he was led to engage in a laborious investigation of the various metaphysical theories of ancient and modern times. With this view, he made himself master of the living languages, especially the French and English, the latter of which he acquired without the aid of a master, in order to enable him to examine into the merits of the British philosophers, particularly Locke, Berkeley, and Hume. To the sceptical conclusions of the last mentioned writer, according to Kant's own confession, the world is indebted for the *Critical Theory*.

Having attained his thirtieth year, and already distinguished himself as the author of several tracts, exhibiting great originality of thought, Kant resolved to devote himself to the profession of a public teacher. With this view, he returned to the university of Koningsberg, and took his degree of M. A., according to the usual forms, in the year 1755. It was upon this occasion that he produced, in the form of an inaugural dissertation, his tract entitled, *Principiorum primorum Cognitionis metaphysicæ nova dilucidatio*; the first of his works, it is believed, which contained any hints respecting his peculiar views of metaphysical science. In the same year, he published his celebrated treatise on the *Universal Natural History and Theory of the Heavens*; or an *Essay on the Constitution and Mechanical Structure of the whole Globe, according to the Newtonian System*. In this treatise, by following out the principles of Newton, he was led to anticipate, in theory, some of the subsequent discoveries of the great practical astronomer, Herschel.

Soon after he had taken his degree, he began to avail himself of the privilege attached to the character of a *Doctor docens*, by delivering lectures publicly on Logic, Metaphysics, Mathematics, and Natural Philosophy; to which, at a subsequent period, he added the Law of Nature, Moral Philosophy, Natural Theology, and Physical Geography. He had not long commenced the discharge of his duties as a public teacher, when the concourse of students, whom

Kant.

the reputation of his profound and extensive learning attracted, was so great, that his *auditorium*, or lecture-room, although large and commodious, could scarcely contain the numbers who eagerly flocked to hear him. His affable manners and social talents, at the same time, rendered him a most acceptable guest at the tables of the most respectable inhabitants of Koningsberg, with several of whom he lived on habits of intimate friendship.

But notwithstanding his acknowledged talents as a philosopher, and his popularity as a lecturer on scientific subjects, it was long before Kant obtained any preferment. With a mind constantly and intensely engaged in the pursuit of knowledge, he appears to have possessed no ambition beyond that of being useful in the sphere he had chosen for the exercise of his abilities; and he had too much simplicity of character to resort to any of those arts, by which other men, more emulous of distinction, frequently endeavour to advance their worldly interests. Upon the death of Knutzen, in the month of April 1756, he solicited the vacant extraordinary professorship of philosophy, but without success. The ordinary professor of Logic and Metaphysics, having died in 1758, Dr Schultz, who, as we have already observed, discovered at an early period the talents of Kant, and continued to patronize him so long as he lived,—exerted all his influence to obtain that situation for his *protégé*. But Kant was again disappointed. Not discouraged, however, by the repeated failure of his attempts to attain independence, he continued to deliver his lectures, and to meditate his writings. In the month of February 1766, he accepted the unsolicited situation of second keeper of the royal library, to which a small salary was attached; and at the same time he undertook the management of a private cabinet of curiosities. But these offices he resigned in 1772, on account of the interruptions to which he was exposed, in showing the books and rarities to strangers.

In the year 1770, Kant at length attained the highest object of his ambition, on his advancement to the ordinary Professorship of Logic and Metaphysics in the University of Koningsberg; a situation, which, while it placed him far above the fear of want, afforded him, at the same time, the best opportunity of employing his talents in a manner satisfactory to himself, and advantageous to his country. Upon this occasion, he produced his celebrated inaugural dissertation, *De Mundi Sensibilis atque Intelligibilis Forma et Principiis*; in which he propounded some of the fundamental principles of that metaphysical theory, to which he was afterwards indebted for his great reputation.

From this period, the life of Kant affords no very remarkable incidents for the pen of the biographer. His time appears to have been chiefly occupied in the faithful and zealous discharge of the duties of his office; in the composition of those philosophical works, by which he hoped to accomplish an important and beneficial reform in metaphysical science; and in cultivating the society of a select number of friends. At this time, too, he maintained a philosophical correspondence with several of the first literary characters of the age, and particularly with the

Kant.

celebrated Lambert, then President of the Royal Academy of Sciences at Berlin, whose views of philosophy were, in some respects, coincident with his own. His letters to Lambert, indeed, are peculiarly interesting, as they contain frequent allusions to the gradual development of his metaphysical ideas.

In the year 1780, he became a member of the *Senatus Academicus*; and, in 1787, he was admitted a member of the Royal Academy of Sciences at Berlin. Never, perhaps, did there exist a mind so ardently and so entirely devoted to the cultivation of science, and so utterly divested of all interested motives in the pursuit of knowledge. Having once attained independence, his ambition, as to worldly objects, seems to have aspired no higher. Although he received, at different times, various invitations, with most advantageous proposals, to induce him to transfer his talents and his reputation to other universities, he could never be prevailed upon to leave his native town; being perfectly satisfied with the advantages he already enjoyed, and with the sphere of usefulness which had been assigned him. For many years previous to his death, he was the senior professor of Königsberg; and he enjoyed that high degree of respect and veneration, which was due alike to his advanced age, his eminent talents, and conspicuous virtues. He died, by a gradual decay of nature, on the 12th of February 1804, in the eightieth year of his age. His funeral was attended by the most respectable inhabitants of Königsberg, and by a numerous train of his friends and disciples; and, to express the public regret for the loss of so distinguished a character, the whole city put on mourning. On his coffin there was placed a sepulchral urn, with the inscription: *Cuores mortalis immortalis Kantii*. A beautiful commemorative medal was also executed upon this occasion, by M. Abramson of Berlin. On one side is a striking likeness of the philosopher, with the inscription—*Immanuel Kant, nat. 1724*. On the reverse, the artist has attempted to express the services of Kant in assigning limits to the province of speculative philosophy, by representing a Minerva seated, and holding an owl in her right hand, which she prevents from flying, with the inscription—*Altius volentem arcuit*.

In his person, Kant was rather below the middle stature, of a slender and delicate form, and with a very narrow and flat chest. His bodily frame, indeed, did not seem to promise longevity; nor would he, in all probability, have attained so great an age, had not his constitution been preserved by his regular and temperate mode of living. In his external appearance, strangers found nothing prepossessing, or indicative of any uncommon talents; on the contrary, his features are represented by a gentleman who visited him at Königsberg, as “a reproach to physiognomy.” Others, however, describe his countenance as full of dignity, and expressive of benevolence. His natural disposition was cheerful and social; and his manners polite and affable. He exhibited none of that awkwardness, or reserve, which is frequently generated, or increased by habits of reclusive meditation, and which is often thought to be characteristic of the scholar and man of science.

Kant.

He loved company, and was both inquisitive himself, and fond of communicating his own knowledge and opinions upon all subjects. There was nothing, however trifling it might appear, at first sight, which did not suggest to his mind some interesting reflections; and he could talk as fluently with a lady on the minutiae of female dress, the mysteries of the kitchen, or the common occurrences of the day, as he could with a philosopher on the most abstruse points of science. He was very regular in his habits. He rose early; and his mornings were generally devoted to study and professional duties; his evenings to society. As he never entered into the married state, he was not encumbered with the cares of a family. He used to say, that when he would have married, he had not fortune sufficient to maintain a wife; and when he possessed the requisite fortune, he had no inclination to marry. It has been remarked, that he was fond of society; and during the earlier part of his life, when otherwise disengaged, he used to dine at the ordinary of the principal tavern; by which means he had an opportunity of acquiring an extensive knowledge of human character, and, at the same time, of gratifying his inquisitive disposition, by eliciting from travellers of different countries many curious and valuable observations on the manners, habits, and literature of various nations. He possessed an intimate knowledge of geography, and even of minute topography, probably in a great measure derived from this last mentioned source, as well as from his private reading of books of travels, to which he was always extremely partial; and he frequently entered into local details with a degree of correctness, which could not fail to astonish those who learnt that he had never moved fifty miles from his native town. At a later period of his life, when more easy in his circumstances, he generally invited a few of his friends to dinner, with whom he relaxed from his graver studies, frequently enlivening his discourse with sallies of wit and humour, of which he possessed no small share, and occasional irony and satire, of that good-natured species which inflicts no wound on the object against whom it is directed.

Kant's intellectual faculties were of a high order. He had a wonderful power of reflection, which enabled him to unfold the most abstruse principles, and to pursue, in his own mind, a long train of conclusions. He possessed great quickness of observation, and clearness of conception; inasmuch that, in conversation, he could describe any object which he had seen, or of which he had read, with admirable precision and accuracy. His memory was exceedingly retentive. He kept no library, but made a contract with a bookseller to send him all new publications, which he perused, and afterwards returned; and the knowledge thus acquired he had always at his command. The most remarkable feature in the moral character of Kant, was an utter abhorrence of every species of falsehood, however innocent, and a love of perfect honesty and sincerity, in word and action, flowing no less from his natural disposition, than from those high principles which he had early imbibed, of the value of truth, and the dignity of man. In this respect he was ever consistent with

Kant.

himself; and the whole tenor of his long life may be regarded as a practical commentary on his writings, and an exemplification of his moral maxims.

The peculiar doctrines of the critical, or transcendental philosophy, were not the offspring of impressions accidentally received, and hastily adopted; but the fruit of long, patient, and systematic investigation. Kant, indeed, was well advanced in years, before he attempted that reform in metaphysical science which he seems to have long meditated. In several of his earlier productions, and in his Letters to Lambert, he evidently appears to have been dissatisfied with the prevailing theories; and his inaugural dissertations, as already mentioned, exhibited some of those peculiar views, which were afterwards more fully developed in his great work, the *Critik der reinen Vernunft*. This work was published in 1781. For several years, it appears to have attracted little or no attention; and the publisher, it is said, was on the point of destroying the sheets, as waste paper, when a sudden demand rapidly carried off several impressions. From that period, the *Transcendental Theory* began to excite an extraordinary sensation, and to be regarded as a new and wonderful discovery in metaphysical science; the philosophers of Germany were divided into professed partizans and determined antagonists of the doctrines of Kant; and a multitude of publications issued yearly from the press, for the purpose of confirming or refuting the new principles.

It was not long, however, before the *Critical Philosophy* bore down all opposition, and obtained a complete ascendancy over the theories inculcated by its adversaries. It was publicly taught in the schools, to the almost total exclusion of the doctrines of Aristotle, Descartes, Locke, Leibnitz, and Wolf; it gave a fresh impulse to the spirit of metaphysical inquiry; and men of the first note in the scientific world felt a conscious pride in being able to comprehend, to explain, to illustrate, to apply, or to extend its principles. It not only effected an entire revolution in German Metaphysics, but exerted a powerful influence on works of taste, and the lighter literature of the country. It is impossible, indeed, to comprehend, or to relish, many passages in the works of the more recent poets, novelists, and fugitive writers of Germany, without some previous acquaintance with the doctrines of Kant.

Owing to what has been already said upon the subject in another part of this work (*Dissertation First, Part Second, Section Seventh*), we shall avoid entering into any discussion respecting the merits of the *Critical Philosophy* in the present article; but we shall present our readers with a very concise abstract of its objects and results.

Mr Hume proved very satisfactorily, that our ideas of *cause and effect* are not derived from experience; but he rashly concluded, as Kant observes, "that they are the spurious offspring of the imagination impregnated by custom." Kant discovered, that Hume had been led to this hasty inference, in consequence of having taken too limited a view of the great problem, which he had thus partially attempted to solve. He perceived that the idea of *cause and effect* is by no

Kant.

means the only one which the mind makes use of with the consciousness of its necessity, yet without being derived from experience; but that the science of metaphysics is altogether founded on ideas of a similar nature. He endeavoured, therefore, to ascertain the precise number of these abstract or transcendental ideas; and having succeeded in this to his own satisfaction, he found himself in possession of the whole of those connecting acts of the mind, which constitute the very elements of the understanding itself, which are indispensable to its exercise, and without which the whole of our experience would exhibit nothing but a number of insulated facts, without order or consistency.

The three original faculties, through the medium of which we acquire knowledge, are *Sense*, *Understanding*, and *Reason*. *Sense* is a passive, or receptive faculty. In the objects presented to our senses, we distinguish *matter* and *form*. The forms or conditions of sense are *space* and *time*. The former of the external; the latter of the internal sense. All our knowledge is limited by space and time; for we can perceive nothing that does not exist under these conditions.

Understanding is an active, or spontaneous faculty, and consists in the power of forming conceptions. In every conception of the understanding, also, we distinguish the *matter* and the *form*. The matter is the sensible intuition; the form is the unity, or connection, established by means of the synthetic powers of the understanding, or the categories. Kant was at great pains in endeavouring to ascertain the number of these synthetic powers, or categories; and he found them to be all comprehended under the four classes of *Quantity*, *Quality*, *Relation*, and *Modality*. The categories themselves are twelve in number. Under the first head are comprised *unity*, *multitude*, *totality*; under the second, *reality*, *negation*, *limitation*; under the third, *substance* and *accident*, *cause* and *effect*, *action* and *re-action*; under the fourth, *possibility*, *existence*, *necessity*.

This synthetic power of the understanding is called, in the critical philosophy, its *original use*. The *logical use*, both of understanding and reason, is to be found in the faculty of *Judgment*. Logic, however, has only to do with the form of our conceptions, and not with their matter; which last inquiry belongs to transcendental philosophy, or Metaphysics.

Reason is the third or highest degree of mental spontaneity, and consists in the power of forming ideas. As it is the province of the understanding to form the intuitions of sense into conceptions, so it is the business of reason to form conceptions into ideas. The ideas of reason are absolute and unconditional, and totally independent of space or time; consequently, we can neither obtain nor extend our knowledge by means of reason alone. For these ideas are nothing more than certain representations of the unconditional,—of the highest unity and totality,—which spring from the essential constitution of our reason, which serve to render the field of experience a comprehensible whole; and which, therefore, are merely conditions of the exer-

Kant. cise of our reason, and not real external objects, of which it is possible to acquire any knowledge by intuition.

The results of the critical theory may be stated, we conceive, in a very few words. The first principles, or conditions, of all our speculative knowledge, are mere *subjective* forms, *i. e.* forms derived from the constitution of the thinking-being: First, the forms of sense, or pure intuitions (space and time); and, secondly, the forms or notions of the understanding (the categories). These intellectual forms or notions, however, only acquire reality by their application to our perceptions, with reference to possible experience; and, therefore, we can have no speculative knowledge of things beyond the sphere of experience.

Besides the critical investigation of pure reason, in its speculative exercise, Kant instituted a similar inquiry into the nature and laws of our *practical reason*, and of the faculty of *Judgment*; and, in the spirit of his own theory, he published the *Metaphysical Elements of Natural Philosophy*, of *Law*, and of *Ethics*. His *Logic*, *Physical Geography*, and some other works, were published, by his friends, from his papers, and the marginal notes to his text-books. Towards the latter end of his life, he meditated a work, which was intended to be the key-stone of his whole system, and which was to have been entitled, *The Transition from Metaphysics to Physics*; in which he proposed to demonstrate the general application of the principles of the transcendental theory. The decline of his faculties, however, prevented the execution of this projected work.

We shall close this article with a list of Kant's publications.

Gedanken von der wahren Schätzung der lebendigen Kräfte, &c. (Thoughts on the true estimation of the animal powers, with strictures on the proofs advanced by Leibnitz and others.) Königsberg, 1746.

Allgemeine Naturgeschichte und Theorie des Himmels, &c. (Universal Natural History and Theory of the Heavens, &c.) *Ibid.* 1755.

Principiorum primorum cognitionis metaphysicæ nova dilucidatio. A Dissertation on taking his Master's degree, in 1755.

Betrachtungen über den Optimismus. (Reflections on Optimism.) Königsberg, 1759.

Von der falschen Spitzfindigkeit der vier syllogistischen Figuren. (On the sophistical subtlety of the four syllogistic figures.) 1763.

Einzig möglicher Beweisgrund zu einer Demonstration des Daseyns Gottes. (The only possible evidence for demonstrating the existence of the Deity.) Königsberg, 1763.

Beobachtungen über das Gefühl des Schönen und Erhabenen. (Observations on the feeling of the Beautiful and Sublime.) 1764. This tract is remarkable on account of the spirit of humour and pleasantry which pervades it.

Träume eines Geistersehers, erläutert durch Träume der Metaphysik. (Dreams of a Ghost-seer, illustrated by the dreams of Metaphysics.) Riga, 1766. This publication was occasioned by the visions of the famous Emanuel Swedenborg.

De Mundi Sensibilis atque Intelligibilis Forma et Principiis. Königsberg, 1770. An inaugural dissertation on obtaining his professorship.

These, along with a number of other tracts, in which the author displayed an intimate acquaintance with the principles of the sciences, remarkable quickness of observation, great depth of thought and acuteness of reasoning, will be found incorporated in the following collections.

Kant's Sämmtliche kleine Schriften. (Kant's Smaller Tracts collected.) 3 Vols. 8vo. Königsberg and Leipsic, 1797.

Kant's Vermischte Schriften, mit Anmerkungen, von Tieftrunk. (Kant's Miscellaneous Writings, with Notes, published by Tieftrunk.) 3 Vols. 8vo. Halle, 1799. A fourth volume was added, Königsberg, 1807.

The early and anonymous essays of Kant were collected and published by F. T. Rink, Königsberg, 1800. In the following works, his peculiar views of metaphysical science, as constituting what has been called the Critical Philosophy, are more fully and systematically developed.

Critik der Reinen Vernunft. (Critical Enquiry into the Nature of Pure Reason.) Riga, 1781. 3d Ed. 1791, 8vo.

Prolegomena zu einer jeden künftigen Metaphysik, &c. (Prolegomena to every Future System of Metaphysics, &c.) 1783. In the *Critik der reinen Vernunft*, the author had proceeded synthetically: in this other work, he adopts the analytical method, with the view of rendering his theory more intelligible to students.

Metaphysische Anfangsgründe der Naturwissenschaft. (Metaphysical Elements of Natural Philosophy), 1786. This is a systematic text-book on pure physics, in which the author treats of those principles in natural philosophy of whose truth we are conscious, *a priori*, *i. e.* independently of experience. The subject is treated under the four heads of Chronology, Dynamics, Mechanics, and Phenomenology.

Grundlegung zur Metaphysik der Sitten. (Fundamental Principles of the Metaphysics of Morals.) 1785.

Critik der Practischen Vernunft. (A Critical Enquiry into the Nature and Laws of Practical Reason.) 1788.

Critik der Urtheilskraft. (A Critical Enquiry into the Faculty of Judgment.) 1790. In this work, the author develops his views of the principles of taste.

Metaphysische Anfangsgründe der Rechtslehre. (Metaphysical Elements of Legal Science.) 1797.

Metaphysische Anfangsgründe der Tugendlehre. (Metaphysical Elements of Ethics.) 1797.

Anthropologie, in Pragmatischer Hinsicht. (A Pragmatical Treatise on Anthropology.) 1798.

The following works were published from his papers by his friends:

Logik (Logic), published by G. B. Jäsche, 1801.

Physische Geographie (Physical Geography), of which, we believe, there have been several editions; by different editors.

Pädagogik (Pædagogics, or the Art of Communicating Instruction). Published by F. T. Rink, 1808.

(H.)

Kent.
Extent and
Boundaries.

KENT, a maritime county in England, and, reckoning its population, extent, and fertility, perhaps the first in the island. It is in a peninsular form, being bounded by the British Channel on the south, by the German Ocean on the east, by the river Thames, which divides it from Essex, on the north, and by the counties of Surry and Sussex on the west. Its length is sixty-six, and its breadth thirty-six miles. The area is calculated to be 1300 square miles.

Divisions
and Popu-
lation.

The divisions of Kent are into five laths, which are subdivided into 63 hundreds and 15 liberties, and contain two cities, 36 towns, and 414 parishes. By the census of 1811, the inhabitants were returned as 373,095; viz. 183,500 males, and 189,595 females. The baptisms of the preceding year, of 6538 males, and 6295 females; the deaths, 5653 males, and 4174 females; the marriages, 3405. The families were, 76,235, of whom 27,077 were employed in agriculture, 27,966 in trade and manufactures, and 21,192 in neither of those branches of industry.

The places containing more than 2000 inhabitants are,

The places whose population is betwixt 1000 and 2000 are, Eltham, Bexley, Crayford, Lenham, Lydd, Westerham, Sittingbourne, Wye, and Malling. The inhabitants of towns are 206,160. Kent returns eighteen members to the House of Commons, viz. two from the county, and two each from Canterbury, Dover, Maidstone, Hythe, Rochester, Queenborough, Sandwich, and Romney.

The appearance of Kent is generally acknowledged to be equal, if not superior, in beauty, to that of any other British county. Its surface is gently undulating; none of its hills, except on the coast, rise abruptly, nor reach a great elevation. In all the

vallies, there are streams of water; the woods and trees enrich the scenery, and the mixture of pasture and corn land, interspersed with orchards, fruit trees, and hop plantations, give to its beauties a character of softness and grace.

Kent.

The Thames may be considered a Kentish river, as it washes its whole northern boundary, and empties itself into the sea on its shores. The river next in importance is the Medway, formed by the junction of four small streams, one only of which rises within the county. It becomes navigable for large barges at Tunbridge, continues its course by Maidstone to Chatham, where ships of the largest size can approach the shore; and there terminates its course, by joining the Thames at the Nore, beyond the arsenal of Sheerness. The Greater Stoure, the Lesser Stoure, the Rother, the Cray, the Darent, and the Ravensbourne, are small rivers, none of them navigable, but all of great benefit, by the fertility they communicate to the meadows on their banks, and by the power they afford to the many mills erected upon them.

Kent is almost exclusively an agricultural county, and though the soil is generally fertile, and though there are few extensive tracts of barren or uncultivated land, yet no part of the kingdom exhibits within so small a compass so great a variety of soils, of productions, and of modes of cultivation. It has been judiciously divided into eight districts for the purposes of agricultural description. The first of these, the Isle of Thanet, is in the north-west angle of the county. The soil is a light mould, on a chalky bottom, and has been highly enriched by the marine substances that have been administered as manure. The whole island contains 23,000 acres of arable and 3500 acres of rich marsh land. The most common rotation of crops is fallow, sometimes with sometimes without a crop of peas; this is followed by barley, clover, and wheat, and on some soils rather heavier, the course pursued is beans, wheat, and barley. The barley of this district is very much esteemed, and sought for as seed in other countries. Besides the common grains, seeds of various kinds are raised for sale to the London seedsmen, particularly canary, radish, spinach, mustard, and onion seed. The soil in the marshy parts of the island is a mixture of clay, sea-sand, and small shells, and yields most abundant pasture.

The upland farms of East Kent, which surround Canterbury and extend to Dover on one side, and Ashford and Rochester on the other, are an open and dry tract of corn land, intermixed with woods. The soils are very various, all resting on a subsoil of chalk. Some of them are very heavy loamy clays, with a great quantity of flint-stones on the surface; these are usually cultivated on a four course rotation of fallow, barley, beans, and wheat; when the soil is somewhat stiffer, a variation occurs of fallow, wheat, beans, and oats. In this district, the harvest usually commences from twelve to fourteen days later than in the Isle of Thanet. The woods in this district usually supply poles to the hop-planters in the vicinity; they are cut down after from ten to fourteen years growth. There are in this division some few hop-grounds, but they are confined to three or

Kent.

Rich Flat
Lands.

four parishes. In the vicinity of Sandwich, Faversham, and Deal, a portion of land, of a rich sandy loam, receives an almost uniform cultivation; it is nearly all under the plough, and a four course rotation is practised of wheat, beans, barley, and oats, after a fallow, or sometimes canary occupies the place of wheat; some portions of this land is alternately cropped with beans and wheat, or beans and canary. In the vicinity of Sandwich are many orchards, whose apples are partly sent to London, and a part furnishes return cargoes to the vessels that come laden with coals from Newcastle and Sunderland.

Hop Ground
Division.

The district extending from Maidstone to Canterbury, and from thence to Sandwich, is the great garden tract for the growth of hops. The soils on which hops are produced are very various; the most productive are those which have a deep loam surface, with a subsoil of deep loamy brick earth, some of these have a considerable quantity of flint-stones mingled with the soil, and when it becomes compact almost covering it. Another soil, provincially called stone shalten, is very good for the growth of hops; it is mixed with many small portions of stone and sand, and rests upon the basis of the stone called Kentish-rag, which is burnt into excellent lime. The cultivation of hops is a very fluctuating pursuit, as the produce varies in different years from two to fifteen hundred weight *per* acre, and the prices have varied from three to fifteen pounds. The expence of cultivation is very great, from the quantity of manure that is required, from the great expence of the poles round which the plants twine, and the labour of keeping the ground clear and of picking the hops. Besides hops, the district is very productive of apples, cherries, and filberts, to the growth of which many fields, from one to ten acres in extent, are devoted; part of the apples are made into cider, the remainder, with the cherries and filberts, are principally conveyed to the different markets in London.

Isle of Shep-
pey.

The Isle of Shepey is separated from the rest of Kent by an arm of the sea called the Swale, which is navigable for ships of 200 tons burthen. Its length is eleven, and its breadth eight miles. About four-fifths of the island is either marsh or dry pasture land; on the former many oxen are fattened, and the latter are appropriated to the breeding and feeding sheep. About 10,000 acres of this island is arable land, of great fertility, usually cultivated with beans and wheat in alternate years, with occasionally a fallow before the beans. This land is highly fertile, the wheat raised on it is considered the best that is brought to London, a bushel frequently weighing 64 lbs. This great productiveness may be in a great measure owing to the practice of applying to the natural heavy clayey soil a frequent dressing of the cockle shells which are washed on the beach by the sea. It is not unusual to apply thirty cartloads of these shells to an acre of land. The Uplands of West Kent are extensive and various in their soils. This part is more woody and inclosed than East Kent. The ridge of the chalk hills, about six or seven miles in breadth, is a stiff clay, with many surface flints, and requires six horses fre-

Uplands of
West Kent.

quently to plough it. On these soils the most common rotation is a year's clean fallow, then wheat, clover, wheat, and oats. Many large flocks of South Down sheep are kept on this hilly range. The vallies and the sides of the hills are lighter soil and easier to work, but do not produce better corn; some of this, but not to a great extent, is cultivated to hops.

Kent.

The district known as the Weald of Kent was, in former times, an immense forest, desolate of inhabit-
ants, and only occupied by wild swine and deer; and though it is now filled with towns and villages, and well peopled, the woods that remain are extensive; these exhibit some pleasing landscapes, where seats, farms, and villages, are mixed with cultivated fields, and woods of spreading oaks. The roads in this district are very bad, many of them impassable for carriages in the best seasons, and, in winter, horses can only travel by keeping on the narrow paved tracts that are formed by the sides of the highways. The soil is principally clay, with a substratum of marl, in some places very heavy, but in others sufficiently light to be ploughed with oxen. This district produces wheat, oats, barley, rye-grass, clover, and beans, but so various are the rotations, that it is scarcely possible to generalise them. The pastures are very rich and fertile, and fatten annually great numbers of cattle. In the western part of this district, and in the adjoining Weald of Sussex, there were formerly many iron-works; the ore is found, and the abundance of wood made the manufacturing of it profitable, but the substitution of coke for charcoal in making iron, has put a final stop to all the iron-works of Kent and Sussex.

The last agricultural division is a rich level extensive tract of land, on the southern coast, containing
about forty-five thousand acres of the richest pasture in the united kingdoms. This level is protected from the violence of the sea, and from inundations, by a dike of earth of very great thickness, called Dimchurch-wall. The whole is alluvial land, consisting of a fine soft rich loam, with portions of sea-sand and broken shells intermixed. The subsoil consists of alternate layers of sand and clay mixed with shells, among which are sometimes found large oak trees in various positions, the wood of which is as black and as hard as ebony. On this plain there are two towns, Romney and Lydd, but scarcely any villages, and few other houses but those of the shepherds and herdsmen who attend upon the numerous cattle that graze on the marshes. As there are no other fences but dikes, or posts and rails, from the surrounding heights it has the appearance of one large verdant field covered with sheep and oxen. The breeding and fattening of sheep is the principal purpose to which this level is appropriated, and the number bred is greater than on any other tract of the same extent in the kingdom. The sheep take their denomination from the district; they are larger than the South Downs, but not of a size equal to the Lincolnshire sheep. Their flesh is highly esteemed in the London markets, and their wool is both fine and of a long fibre; the average weight of the fleeces is about five pounds.

The landed property of Kent is much divided; there are some noblemen that have large, but none party.

Kent.

such vast estates as to give a preponderating political influence. The number of freeholders exceeds ten thousand, enjoying estates from the smallest value that can give a vote, and gradually rising to L.7000 or L.8000 *per annum*. The copyhold tenures are very few, and the peculiar tenure of Kent, known as *gavel-kind*, is very much diminished by various legal operations.

Private
Manufac-
tures.

The *private* manufactories bear no proportion to the extent, wealth, or population of this county. The cloth trade, which was first introduced at Cranbrook, has entirely forsaken the county. A few descendants of French Protestant refugees carry on the manufacture of the richest brocaded and other silks. The best writing paper is made in the vicinity of Maidstone, and some near Westerham. There are some silk mills at Sevenoaks. At Crayford are extensive calico printing and bleaching works. At Dartford are mills for manufacturing iron. Such are the few private manufactures, none of which are extensive; but those of *government*, in this county, give employment to vast numbers of workmen. The greater part of the implements of land and sea warfare are prepared in Kent. The establishment at Woolwich, for the artillery, is certainly the most extensive and best regulated collection of various workshops and storehouses in the world. Mortars and brass cannon are cast, bored, and mounted, the different kinds of shot and shells prepared, and all the various combustibles used in war completed. The whole establishment under the Board of Ordnance, including the Academy for the instruction of the cadets, the Artillery Barracks, and the Arsenal, exhibit the wealth of the country, and the power of the government, in directing that wealth to the purposes of war.

Military
Arsenal.Naval
Arsenals

There are four naval arsenals in Kent, viz. Deptford, Woolwich, Chatham, and Sheerness. In the three last of these, first-rate ships of war are built, and at Deptford the largest two-deckers. In this latter place is the principal store-house for provisions for the navy,—the slaughter-house, where, in time of war, hundreds of hullocks and pigs are killed; also possessing proper places for curing their flesh for future consumption. When the whole coast of the opposite continent was in the hands of a hostile nation, it was deemed advisable by the government to create a more considerable arsenal, where a fleet might at all times be ready, or, if necessary, be repaired, so as to oppose the force, without waiting for any change of wind, that was collecting in the Scheldt. A plan was then formed for constructing at Purfleet a naval arsenal upon a most magnificent scale. It has been begun by excavating the chalk rocks; and though the altered condition of Europe may make such an establishment less necessary, it is still in progress, though not proceeding rapidly.

Greenwich
Hospital
and Obser-
vatory.

One of the proudest ornaments of the nation, Greenwich Hospital, for the relief of disabled or aged seamen, is in this county; and, in the park contiguous to it, the Royal Observatory, to which the eyes of all the navigators of Europe are directed, as the place from which issues the nautical Ephemeris, that all nations depend on when traversing distant seas.

Though Kent is bounded on three sides by the ocean and the River Thames, it has scarcely any foreign commerce. The harbours are none of them good; those of Dover and Ramsgate are formed by artificial piers, and the former is dry at low-water when the sluices are open. The only trade from Dover is to Calais, Dunkirk, and Ostend, for such light goods as can bear the expence of land-carriage. There is a herring fishery conducted from Folkstone; besides which, the principal foreign trade consists in smuggling those various articles, whose high duties offer a temptation to encounter such perilous adventures.

The sea-shores in this county invite numerous visitors, who frequent and fill various towns during the warm months of summer. The principal of these are Margate, Ramsgate, and Broadstairs; but, besides these, many of the smaller places on the coast are resorted to for purposes of health or amusement. On the western side of the county, the waters of Tunbridge have been long celebrated; and though the influence of fashion has erected into rivals several other Spas, yet the company that still resort to it is both numerous and respectable.

KENTUCKY. See the Article UNITED STATES.
KERGUELEN'S LAND, or ISLAND of DESOLATION, an island in the Southern Indian Ocean (long. 69° 30', east lat. 49° 20' south), discovered by Kerguelen, a Frenchman, and visited in the year 1779 by Captain Cook, who gave it the latter name, from its appearance. This land occupies about one degree and a quarter of latitude, and probably about two of longitude. The French discoverers imagined it to be the projecting part of the supposed southern continent, since proved to have no existence. The following observations on its natural productions were made by Mr Anderson, surgeon to Captain Cook:—Perhaps no place hitherto discovered, in either hemisphere, under the same parallel of latitude, affords so scanty a field for the naturalist as this barren spot. The verdure which appears when at a little distance from the shore, would flatter one with the expectation of meeting with some herbage, but in this we were much deceived; for this verdant colour is produced only by one small plant, not much unlike some sorts of saxifrage, which grows in large spreading tufts, to a considerable way up the hills. It grows on a kind of rotten turf, which dried, in cases of necessity, might serve for fuel, and is the only thing we met with here that could possibly be applied to this use. There is another plant growing plentifully about the boggy declivities, to near the height of two feet, and not much unlike a small cabbage, when it has shot into seed. Two other plants were found near the brooks and boggy places, which were eaten as sallad; the one resembling garden cresses, and very fiery; the other very mild; this last, though but small, is in itself a curiosity, having not only male and female, but what the botanists call *androgynous* plants. A coarse grass grows in some spots, about the sides of

Kent
||
Kerguelen's
Land.
Commerce.

Kerguelen's the harbour, and a smaller sort, which is rarer. In short, the whole catalogue of plants does not exceed sixteen or eighteen, including some sorts of moss, and a beautiful species of lichen, which grows upon the rocks higher up than the rest of the vegetable productions; nor is there even the least appearance of a shrub in the whole country. The animals found here are all of the marine kind, and use the land only as a resting place, and for breeding; the most considerable are seals; no other quadruped, either of the sea or land kind, was seen; but a great number of birds, viz. ducks, petrels, albatrosses, shags, gulls, and sea-swallows. The hills are of a moderate height, yet many of their tops were covered with snow when the island was visited by Captain Cook, though it was in the month answering to our June. Rain must be almost constant here, not only from the marks of the torrents, but from the disposition of the country; which, even on the hills, is an entire bog. The foundations of the hills are composed chiefly of a dark blue, and very hard stone, intermixed with small particles of glimmer or quartz. Another brownish brittle stone forms here some considerable rocks; and one which is blacker, and found in detached pieces, incloses bits of coarse quartz. A red, a dull yellow, and a purplish sandstone, are also found in small pieces; and pretty large lumps of semi-transparent quartz, disposed irregularly in polyedral pyramidal crystals of long shining fibres. Some small pieces of the common sort are met with in the brooks, made round by attrition, but none hard enough to resist a file; nor were any of the other stones acted on by aquafortis, or attracted by the magnet. Nothing that had the least appearance of an ore or metal was seen.—*Edinburgh Gazetteer, or Geographical Dictionary.*

Situation. KERRY, a county in Ireland, situated on the south-west coast, between 51° 30 and 52° 24 north latitude. Its boundaries are the river Shannon on the north, the counties of Cork and Limerick on the east, and the Atlantic on the south and west. From north to south it extends about 60 English miles; from east to west 54; and its area, according to Smith's history of the county, is 1,030,193 English acres, or, according to Wakefield, 1,763 square miles, or 1,128,320 acres. It is in the province of Munster, and archbishopric of Cashel. The sees of Ardfert and Aghadoe, between which it was formerly divided, were united to that of Limerick in 1663. The present divisions are eight baronies, and eighty-four parishes.

Sea-Coast. The sea-coast of Kerry, from the river Kenmare on the south, to the estuary of the Shannon on the north, extends about 30 leagues. At both these places there is a sufficient depth of water, and good anchorage. The other bays are, Dingle, or Castlemain, and Tralee, with a number of smaller landing places, none of which are much frequented. Kenmare, Dingle, and Tralee, run so far up into the land as to form two peninsulas, which, projecting into the Atlantic, are terminated by several bold headlands, of which Dunpaul, on the north of Dingle Bay, is perhaps the most westerly land in Europe. Dursey, Scariff, the Skelligs, Valentia, the Blasques, and the Magharees, are islands on the coast. Of these, Va-

lentia and the Magharee islands are noted for their fertility, producing the best wheat and other kinds of corn in the district.

More than three-fifths of Kerry is mountainous Surface and waste; and, at the time of Young's Tour, in 1779, did not yield to its proprietors more than 3d an acre. The southern quarter, from Kenmare to Dingle Bay, with the exception of some narrow tracts on the banks of the former river, is almost entirely composed of high grounds, among which Macgillycuddy's Reeks rise to the height of 3000 feet, and Mangerton to about 2700. These mountains are chiefly occupied with young cattle and goats; sheep, apparently the most profitable animal in such situations, are neither numerous nor of a valuable kind; and the little cultivation to be found here is so generally performed with the spade, that, in some entire parishes, as Mr Young assures us, there was not a single plough. To the north of Dingle Bay, about Tralee and Castle Island, the country becomes more productive, and much of the land is employed in keeping dairies, the produce of which, chiefly butter, is sent to Cork and Limerick, yet here, as in the rest of the district, marshes and bogs occupy a large proportion of the surface.

The prevailing soil in the low grounds is clay, of several different qualities; some of it seems to be a species of pipe clay, and other sorts might be converted into bricks and earthenware. Marland ochre have been found in several places. Limestone, sandstone, and marble of different colours, but all variegated, are very common. Slates, of a good quality, are found on the side of a mountain near Killarney; and in the same quarter are copper mines, which were worked with considerable success in 1808, but discontinued in 1811. Iron ore, though found in great plenty in the southern baronies, is of little value, owing to the want of wood and coal. Lead has been discovered in several parts, but does not appear to be wrought. The *Lapis Hibernicus*, or Irish slate, is found near Castle Island; crystals, called *Kerry Stones*, many of them so hard as to cut glass, are got among the cliffs and rocks of the coast; and very fine amethysts near Kerry-head, on the south side of the entrance to the Shannon.

The principal streams are, the Blackwater, which, for some distance, forms the boundary with Cork; the Feal, which rises on the borders of Limerick, and unites with the Gale and the Brick to form the Cashin, which is rendered navigable for small vessels by the tide; the Mang, which receives several streams in its progress, from the mountains on the confines of Cork, where it has its source, towards the sea, is navigable to the bridge at Castlemain, a little above the bay of that name; the Lea is a small stream that falls into Tralee Bay; the Flesk enters the Lake of Killarney, of which the Laune is the only outlet. In the mountain districts, there is a number of brooks, which swell to considerable torrents after heavy rains, but the only stream of any note in this quarter is Kenmare, which gives its name to an arm of the sea near the southern boundary. Most of these and the other rivulets of Kerry abound with trout, and several of them with salmon. Besides the celebrated Lakes of Killarney, for which see KILLARNEY, in the

Kerry.	<p><i>Encyclopædia.</i> Kerry contains several considerable pieces of fresh water. Lough Quilau, on its southern boundary, is remarkable for its floating islands. Mineral waters have been found near the town of Killarney, in the barony of Ineragh on the coast, in the northern barony of Iraghtic Connor, near Dingle, at Castlemain, and at Tralee, the last of which, according to Smith, has been found of great benefit in several disorders.</p>	<p>Young, Beaufort, Newenham, and Wakefield, quoted under the former Irish counties.</p>	Kerry Kildare.
Fish.	<p>Kenmare and the Bay of Dingle are frequented by a great variety of fish, and oysters and other shell-fish abound in their creeks and harbours, and at the mouth of the Shannon. Herrings visit the coast in August and September. The sea-calf, <i>vitulus marinus</i>, the <i>sepia</i> or cuttle-fish, the <i>urtica marina</i> or sea-nettle, are found on the coast; the first in great numbers on the shores of the Kenmare, where they are very injurious to the salmon-fishery.</p>	<p>KILDARE, an inland county of Ireland, bounded on the north by Meath, on the east by Dublin and Wicklow, on the south by Carlow, and on the west by King's and Queen's Counties. It is about 41 miles long, and 27 broad, and contains 242,245 Irish or 392,397 English acres; of which four-fifths are arable, meadow, and pasture, and the remainder bog. Kildare forms part of the province of Leinster, its see is in the archbishoprick of Dublin; and the divisions are baronies and half baronies, of which there are fourteen in all, subdivided into 113 parishes.</p>	Situation. Extent.
Estates.	<p>Kerry is divided into estates very large, both in extent and value, some of them, according to Mr Wakefield, worth L. 30,000 a-year. Leases are in general for thirty-one years and three lives, and a considerable portion of the whole county is let to partnership tenants. Few of the tenants in the north quarter about Kerry-head occupy so much land as to require them to employ labourers; they pay their rents by the sale of butter and pigs, and by turf which they carry to Limerick. It is the practice for farmers to hire large tracts which they stock with cows, and these cows are then let out to dairymen, upon such terms as leave them but a very small return for their labour. The best corn land is about Tralee, and towards Dingle, where more flax is raised than in any other part of the county. In the neighbourhood of Tralee, land lets as high as 10 guineas the Irish acre.</p>	<p>Part of the Bog of Allen and other similar tracts occupy a large portion of the western side of this county. The surface is varied by a number of small hills and gentle declivities, but for the most part it is flat and nearly level, and when viewed from a commanding station, presents a rich, and on the banks of its rivers, a beautiful landscape. The Curragh of Kildare, extending to about 5000 acres, has been long celebrated for the softness of its turf, and the fineness of its pastures. But the climate of Kildare is said to be more moist than that of any other part of Ireland, which, if the statement be correct, is a very unfavourable circumstance, as a clay soil prevails very generally, and much of it is exceedingly tenacious of moisture.</p>	Surface.
Products.	<p>The principal articles which Kerry affords for export are its raw produce, beef, butter, hides, and tallow. It does not raise more corn than is necessary for its own consumption, and carries on no manufacture for sale, but that of coarse linen, which is only on a small scale. It has orchards, from the produce of which cyder is made; but little timber and not many plantations. The towns are Tralee, the county town; Dingle; Killarney; Ardfert; Castle Island, and Listowel. Tralee, which contains about 7000 inhabitants, and Killarney 5000, are the most considerable. The county, in which Lord Kenmare's influence preponderates, sends two members to Parliament, and the borough of Tralee, of which Sir Edward Denny is patron, a third. The population, in 1792, is stated by Beaufort at 107,000, but it is understood to be considerably greater at present. In 1733, the Catholics were to the Protestants as twelve to one; but according to Mr Wakefield's information, the Catholic population is now one hundred to one. One half of the non-commissioned officers of the militia, and five-sixths of the privates, are Catholics. In 1811, the wages of common labour were 1s. a-day; potatoes 4d., and oats 10d. per stone; beef and mutton 5d. per pound; milk 2½d., butter milk, in summer 1d., and in winter 2d. per quart.</p>	<p>Kildare is watered by several streams, of which the most considerable belong to other counties. The Liffey entering it from the county of Dublin, to which it returns, traverses its north-east quarter in a circular direction. The Boyne, which rises within this county, in the Bog of Allen, and washes it on the north-west, does not become a considerable stream till it has passed into Meath. The Barrow has its sources in part from the same bog, and flows in an opposite direction through the south-west quarter. Kildare has the advantage of an inland navigation by the grand canal, which entering it from the north-east, proceeds in a west and north-west direction, till it passes into King's County. At Lowton a branch of this canal leaves the main trunk, and advances to the town of Athy, on the south-west boundary, and from this the navigation is continued southward on the River Barrow, which, soon after leaving Athy, becomes the boundary with Queen's County. The Royal Canal also passes through the northern quarter from east to west, and then enters the county of Meath on the north-west.</p>	Rivers. Canals.
Representa- tion.	<p>See Smith's <i>History of Kerry</i>, and the works of</p>	<p>There are a few large estates in Kildare, particularly the Duke of Leinster's, which extends over a third of the county; and several proprietors, according to Mr Wakefield, have from L. 6000 to L. 7000 a-year. Yet many are less considerable, and property seems to be more divided here than in most of the other districts of Ireland.</p>	Estates.
Prices.	<p>See Smith's <i>History of Kerry</i>, and the works of</p>	<p>The common size of farms is from 10 Irish acres to 200, and these farms are frequently held in partnership. Larger farms, however, are less rare here than in the arable tracts of the other counties. The leases were formerly for thirty-one years, but are now mostly for twenty-one years and one life. All parish and county taxes are paid by the tenant.</p>	Farms.

Kildare
||
Kilkenny.

With few exceptions, the course of cropping is the same as it has been for a century, viz. fallow, wheat, oats. Potatoes are universally cultivated. Oxen are employed in ploughing, and horses for carriages; but in many instances oxen and horses are mixed together in the plough team, which sometimes consists of six, and never less than four animals. A number of mules are also kept on the farms. The rent of the arable and pasture land in 1807 was estimated at a little more than 20s. the Irish acre, or about 12s. the English.

Towns, &c.

Kildare has no large towns. Athy on the Barrow in the south-west, and Naas on the north-east, are alternately the assize towns; the others are Kildare, Monasterevin, Castle Derrot, on the south and west, and Leixlip, Maynooth, and a few others, on the north and east. At Cellbridge on the Liffey, a woollen manufactory was established some years ago by a company from Yorkshire. In the Catholic seminary at Maynooth, about 300 students are accommodated with lodgings, commons, and instruction. Each student pays a small sum as entrance-money, which, with his other expences, may amount to L. 20 a-year; the charges of the establishment being chiefly supported by an annual grant from Parliament.

Representa-
tion, &c.

The county, in which the Duke of Leinster is the greatest freeholder, sends two members to Parliament, but Kildare has no parliamentary boroughs. The population, in 1790, was 56,000, but is said to be now nearly doubled. In 1811, taking the inhabitants throughout, the Catholics were in proportion to the Protestants as thirty to one. In the same year wages and the prices of necessaries were higher than in most other parts of Ireland, common labour being quoted by Mr Wakefield at 1s. 6d. a-day for men, and 10d. for women and children; and in hay and corn harvest 2s. 8d. Potatoes were 5d. a stone, beef and mutton 6d. per pound, oatmeal 18s. per cwt. milk per quart 2d., and butter-milk $\frac{1}{2}$ d. in summer, and $\frac{3}{4}$ d. in winter.

Wages and
Prices.

See Rawson's *Statistical Survey of Kildare*, and the works already quoted under the Irish counties. (A.)

Situation.

KILKENNY is an inland county in the Province of Leinster, in Ireland, bounded on the north by Queen's County and Carlow, on the east by Wexford, on the south by Waterford, and on the west by Tipperary. The Barrow flows along the eastern boundary, and the Suir on the southern, forming the lines of separation between Kilkenny and the counties of Wexford and Waterford. Kilkenny, the county town, is in north latitude $52^{\circ} 35'$, west longitude $9^{\circ} 50'$. According to the agricultural survey, its area is about 610,000 English acres, which is divided into nine baronies, besides the liberties of the towns of Kilkenny and Callen, and one hundred and forty-seven parishes.

Surface, &c.

The general appearance of this county is mountainous, yet there are some rich and beautiful tracts on the banks of the Barrow and the Suir, and also on the Nore, which flows through its centre; and several romantic wooded glens, watered by mountain streams. It is ornamented by a great many gentlemen's seats; and its flat districts, where the tillage farms are more extensive than in most parts of Ireland, present a prospect very different from

what is often met with in that country. Much of the soil is incumbent on limestone; no great portion is occupied with bogs, of which, however, there are some considerable tracts near Urlingford and Callen on the west side; and the climate is said to be less humid than that of Dublin and Wicklow, which lie to the north-east, although the west winds prevail for about two-thirds of the year. During summer the thermometer ranges between 70° and 75° , and seldom sinks below the freezing point in winter.

Kilkenny.

Coal has been wrought for many years in Kilkenny. The largest colliery in Ireland is at Castle Coomer, near the northern boundary of the county. It is a stone coal, raised in immense pieces, but of a sulphureous quality, which renders it disagreeable, and sometimes noxious, and it is, therefore, less fit for being used in families. For this reason, and also from the great expence at which it is raised, English coal is used in preference, even within a few miles of the works. There are several quarries of marble, chiefly of a black colour, of which a few tons are exported; and also quarries of excellent sandstone. Manganese, and iron and lead ores, have been observed in different parts. Jasper, of a deep red colour, in pieces of 10 or 12 inches long, and half as broad, has been found on the estate of Sir Edward Loftus, near the extremity of the granite district, between the Nore and the Barrow. There is a chalybeate spring of some celebrity at Ballyspellin.

Kilkenny contains several large estates, and many of a moderate extent, not exceeding a rental of L. 2000 a year. The principal proprietors are Lords Besborough, Clifton, and Ormond. The leases are in general for three lives, and partnership leases are common, though prohibited on one of the largest properties. On this estate the tenant is allowed to transfer his lease to one individual, but not to divide his farm. In 1809 the rent which might have been got, if all the leases had then expired, was estimated at 40s. or 42s. the acre, equal to about 25s. the English acre.

Of the husbandry of this county, the most important department is the dairy, which extends over the greater part of it. The most considerable dairies are in the district called the Welch or Walsh mountains, a tract of dry grassy land fit for tillage, but still in its natural state, and not inclosed. Above 2000 Irish acres of this land were held in 1800 by one family, who kept 120 cows. The cattle are not for the most part housed in winter, and only those that are about the time of calving get a little hay on the fields, where the horses also are kept all the year. They fatten pigs to the weight of five cwt. The produce of the best dairies is $1\frac{1}{2}$ cwt. or three firkins of butter per cow, and each cow requires from $1\frac{1}{2}$ to 3 Irish acres. The practice of letting cows to dairymen, which is common in Munster, is but little known in Kilkenny, the cows belonging to the dairymen themselves, who, in some situations, breed them on their own farms, and in others prefer buying them at a proper age. Too little attention is paid to cleanliness in these dairies, especially in the northern district; and for this reason, according

Dairies.

Kilkenny. to Mr Wakefield, though Irish butter, when fresh, is preferable to any in Europe, yet it "is in the lowest estimation in the London market, as it is almost always heavily salted, and very frequently tastes smoky, fishy, and tallowy." The cattle of this county are a mixed race from the native breed and the English long-horned, and their sheep have been in some parts improved by the introduction of the Leicesters. The Merinos have been introduced within these few years by Messrs Nowlan, the proprietors of a woollen factory, who have now 600 of the pure race, and they find that both the quality and the weight of the fleece have improved since the sheep were imported. The same corn crops are raised here as in other parts of Ireland, but clover and other green crops not in a suitable proportion. It is the custom to work oxen intermixed with horses, in teams of six, or three pair deep, the oxen placed foremost. Yet the fallows are better managed here than in any other part of Ireland. Irrigation has been practised for many years, but not extensively.

Salmon Fish-ery. The rivers of this county, the Suir, the Barrow, and the Nore, have been long celebrated for their salmon, but the quantity, particularly in the Nore, has decreased very much within the last 50 years. They are now sent to Dublin packed in boxes with ice, as is done in Scotland, for the London market, a practice said to have been borrowed from the Chinese. The salmon peal, a fish resembling the salmon, but not so large, is also found in the Nore.

Manufac- tures, &c. The most important manufacturing establishment in Kilkenny, and perhaps in Ireland, is the woollen factory of Messrs Nowlan and Shaw. These gentlemen not only produce superfine cloths, of acknowledged excellence, but the arrangements which they have adopted in carrying on the various processes are so peculiar, and have been so successful, as to render their works, like those of Mr Owen at New Lanark in Scotland, an object of very general curiosity and interest to strangers. Mr Radcliff, the secretary to the Farming Society of Ireland, has recently described these in a *Report* to that Society, which has been reprinted in the *Farmer's Magazine* for August 1820. In the town of Kilkenny there is a manufactory of blankets; and a few years ago there was a school there for teaching lace-making. The Suir, on the south boundary, is navigable for small vessels to Clonmell, and the Barrow, on the east, to Carlow, where it meets a cut from the grand canal to Dublin. These rivers afford great facilities both to the internal and export trade of the district. The Nore is also navigable from the Barrow, into which it flows, to the town of Thomastown, within a few miles of the town of Kilkenny.

Towns. Kilkenny, the county town, contains a population of 15,000. (See **KILKENNY** in the *Encyclopædia*.) The other towns are Gowran, Thomastown, Callen, Knocktopher, and Inistioge. The population of the county, in 1800, was 100,191, of which only 731 families, or 4886 individuals, were Protestants. Five Catholics are called on the grand jury. Kilkenny is the only town that returns a member to Parliament, and two are sent from the county.

See Tighe's *Agricultural Survey of Kilkenny*, and

the general works referred to under the Irish counties.

KINCARDINESHIRE, or, as it is frequently called, the Mearns, a county in Scotland, situated between 56° 43' and 57° 5' north latitude, and 1° 47' and 2° 30' west longitude, from Greenwich, is bounded on the east by the German Ocean, on the north by the river Dee and Aberdeenshire, and on the west and south by the county of Angus or Forfar. It is of a triangular form, extending 32 miles from south-west to north-east, and where broadest, 24 miles from south to north, and contains 380 square miles, or nearly 243,444 English acres, besides about two miles of lakes.

About the half of the area of this county consists of hills and heaths, of little value; somewhat more than a fourth is in regular cultivation, and the remainder is partly improveable land, and partly planted. The most productive land lies along the coast from the town of Stonehaven to the river North Esk, which forms the boundary with Forfarshire, and in the *How* (hollow) of the Mearns, a continuation of the valley of Strathmore, a district which lies to the westward of the coast lands, and immediately south from the Grampians. The Grampians, comprising a third of the area, stretch through its whole breadth from west to east, and, with very few exceptions, are exceedingly sterile and rugged, and very thinly inhabited. About three miles from the coast, this tract rises to the height of from 500 to 600 feet, after which a succession of dark brown hills rapidly increase in altitude, till, at the western extremity of the county, about twenty miles from the sea, the highest of them, Mount Battock, springs to the height of 3500 feet.

The climate of Kincardineshire varies much in its different districts, but is, upon the whole, more rigorous than that of other parts of Scotland in nearly the same latitude. This is chiefly owing to a large proportion of its surface being occupied with the Grampians, on some parts of which snow remains all the year. According to tables given in the *Agricultural Survey*, the averages of the years 1805, 1806, and 1807, afford a medium of 43.8 of heat, 127 days of rain, 30 of snow, and 208 of dry weather.

There is no coal in this county, and limestone is far from being abundant. Native iron, in detached pieces, has been found at Balnakettle, in the parish of Fettercairn, where there is no indication of iron ore. Granite, basalt, puddingstone, and sandstone, are the prevailing rocks, especially the first, of which, with few exceptions, the Grampians are composed. Blocks of granite are scattered over the surface, particularly on the north; and much of the soil in this quarter has been formed from the decomposition of this rock. Along the coast, south from Stonehaven, there is a very fertile soil, consisting of decomposed basalt, or *rotten rock*, as it is called; and here also is a soil remarkably full of small round stones, which, though on this account a little more troublesome to cultivate, is nevertheless very productive. Puddingstone also abounds in this quarter; in the parish of Kinneff it is formed into millstones; in other places, it is in small pieces, which sometimes falling out of the precipitous front which much of the sea coast

Surface

Climate

Minerals

Kincardineshire.

assumes, leave convenient recesses for the incubation of sea-fowls. Sandstone prevails in the tract along the coast, and also in the *How* of the Mearns, the soil of which is a loam of various qualities, but generally fertile, and of a colour resembling that of the sandstone, which is for the most part red or grey. Moss, moor, and beds of barren gravel abound even in the lower parts of the county. The banks of the Dee, on the north boundary, are well covered with wood; and in the *How* there are many thriving plantations; but much of the coast lands are naked, and the Grampian district, throughout its whole extent in this county, has an aspect remarkably gloomy and desolate. The hill of Cloachnabane, 2370 feet high, is distinguished by a mass of naked rock upon its summit, from 80 to 100 feet in perpendicular height, which, when viewed from a short distance, has much the appearance of the ruins of a fortification.*

The rivers are the Dee, which flows for about eight miles through the northern part of the county, and is the boundary for fourteen miles more between this and Aberdeenshire; and the North Esk, which for about ten miles separates it from Forfarshire. Of the other streams, none of which are considerable, the principal are the Cowie, the Carron, and the Bervie, which fall into the sea; the Luther, which joins the North Esk; and the Dye, the Avon, and the Canny, which discharge themselves into the Dee. The Loch of Drum, partly in Aberdeenshire, and the Loch of Leys, both in the Dee side or northern district, each of them between two and three miles in circumference, are the only lakes worthy of notice. In the Loch of Leys there is a small artificial island, founded on piles of oak, on which are the ruins of an edifice, about which tradition is silent.

In 1807, Kincardineshire was divided among eighty proprietors, including two communities, fifteen or sixteen of whom held in feu. According to the *Agricultural Survey* of that year, the large estates had been long in the same families, two of them for 650 years, and about two-thirds of the whole county had been thus possessed for more than a century. In 1811, the number of estates was eighty-six, and of the freeholders seventy-three. The valued rent is L. 71,921, 1s. 4d. Scots, about a fourth of which then belonged to estates held under entail; and, in the same year, the rent of the lands, as returned under the property-tax act, was L. 159,895, 19s. 2d., and of the houses L. 9235, 2s. Sterling. The cultivated parts are in general divided into farms of less than 200 English acres, among which there are many spots, held directly from the landlords, of only five or six acres. In the hilly districts the farms are necessarily large, but of so little value, that some extensive tracts in the Grampians, from the abundance of game, afford a higher rent, when let out to sportsmen for the season, than could be got from farmers. The rent of corn land may be from 20s. to 25s. an acre, though much of it is higher. Few of the leases are for more than nineteen years, and many of them are for shorter periods.

Agriculture.

Modern agriculture has not made such general progress in Kincardineshire, as in the more southerly counties of Scotland, yet nowhere have proprietors (among whom the late Mr Barclay of Urie was,

in this respect, the most conspicuous) incurred a greater outlay per acre in the improvement of land. In some instances, the removal of stones, preparatory to cultivation, has cost about L. 20 an acre. All the different kinds of corn, pulse, roots, and herbage grown in Scotland are cultivated here. Upon the pastures of the arable land the stock of cattle kept is nearly at the rate of one for every Scots acre, but five acres of the high lands are required for the support of a single sheep.

The towns and villages of Kincardineshire are but few in number, and small in respect to population; and its manufactures are inconsiderable. Stonehaven, the county town, is situated on the coast, about fourteen miles from Aberdeen; the town, with the parish of Dunottar, in which it stands, contained, in 1810, 1886 inhabitants; who are partly employed in rope-making, and in the manufacture of canvas and osnaburgs. Bervie, or Inverbervie, a royal burgh at the mouth of the Bervie, about ten miles south from Stonehaven, employs about two-thirds of its population, amounting, in 1811, to 927, in the same manufactures, with the addition of a soap-work, a spinning-mill for lint, a bleachfield, and a thread factory. Gourdon, the sea-port of Bervie, about a mile and a half to the south-east, is a small place, chiefly occupied by fishermen. The village of Johnshaven, four miles south of Bervie, contained about 1000 inhabitants, partly mechanics, and partly seamen. Laurencekirk has about 1300 inhabitants, and is noted for its beautiful varnished snuff-boxes, made of wood. At Inverie there has been a woollen manufactory on a small scale for several years. The other villages are Auchenblae, Marykirk, Fettercairn, St Cyrus, Drumlethie;—a few others for fishing are scattered along the coast.

The external commerce of the county, besides its trade in sheep and cattle, consists chiefly in the import of timber, coal, and lime, and the export of grain and fish, at the ports of Stonehaven, Gourdon, and Johnshaven. In 1807, Stonehaven had 8 vessels, of from 30 to 150 tons; Gourdon 6 vessels, carrying in all 192 tons; and Johnshaven 12, amounting to 197 tons; and about 300 hands were employed in the white-fishery, from villages spread over a line of coast extending from Aberdeen to Montrose, a distance of 37 miles. The value of the fish caught was estimated at L. 6000. The salmon-fishing belonging to this county, on the North Esk and the Dee, and on the Water of Bervie, was then let at about L. 2700 a-year.

Among the antiquities of Kincardineshire the most worthy of notice is a Roman camp, remarkably entire, near the mansion house of Fordoun: Fenella's Castle, about a mile and a half west from Fettercairn, where there are the remains of a vitrified wall; and Dunottar Castle, long the residence of the Earls Marischal, about a mile south from Stonehaven, on a peninsula, projecting into the sea. The regalia of Scotland were deposited in this castle during the civil wars of the seventeenth century.

Kincardineshire contains eighteen entire parishes, and part of three more, two of which are partly in Aberdeenshire, and the greater part of the third in Forfarshire. The parishes to the south of the Gram-

pians, thirteen in number, form the Presbytery of Fordoun, which belongs to the Synod of Angus and Mearns, the rest are attached to the Presbyteries of Aberdeen and Kincardine O'Neil. In conjunction with Angus, this county furnishes a regiment of militia, and a few years ago, it raised two regiments of volunteers, which were afterwards formed into one regiment of local militia, containing 816 rank and file. The county sends one member to Parlia-

ment, and Bervie, its only royal burgh, unites with Kincardine-shire Aberdeen, Brechin, Arbroath, and Montrose, in electing a member for the burghs. The population in 1800 and 1811 will be seen from the annexed abstract.

KING'S COUNTY, an inland county in the province of Leinster in Ireland, bounded by Meath on the north, Kildare and Queen's County on the east, Tipperary on the west and south-west, and Galway, from which it is separated by the Shannon on the west. From east to west, its general length is about seventeen Irish miles, its greatest breadth, from north to south, thirty-one, and it contains, within an outline of one hundred and thirty miles, seven hundred and fourteen English square miles, or about 457,000 English acres. Almost the half of this consists of bogs, mountains, and waste, and the remainder is arable, meadow, and pasture of a medium quality. It is divided into eleven baronies, and fifty-two parishes, the latter belonging to the sees of Kildare, Killaloe, Meath, Clonfert, and Ossory.

The form of this county is very irregular. Its breadth on the western side is suddenly contracted by Queen's County on the south-east, and further to the east, by Kildare and Meath. A small district of it is entirely surrounded by Kildare. The interior is, with few exceptions, a dead flat, though considerably elevated. The only mountains are those of Sliebh Bloom on the boundary with Queen's County, a range which extends for about fifteen Irish miles, and has but one pass, called the Gap of Glandine, which is steep, craggy, and very narrow. The Bog of Allen occupies a considerable tract on the north-east.

The soil of the arable land is, for the most part, either moorish or gravelly, the former tolerably pro-

ductive in dry, and the latter in moist seasons, but neither of them naturally fertile. Limestone, and limestone gravel, the means of their improvement, abound every where. The pastures, though in many parts fine, are not luxuriant; better adapted for sheep than cattle, and very favourable to the growth of fine wool. Much of the mountain district has an argillaceous soil, thickly interspersed with rocks of sandstone, and a deep irreclaimable bog often occurs at its base; but towards the centre of this range, where limestone prevails, there is much good pasture, and here the base of the hills, which is composed of a stiff clay, produces abundant crops of corn. The only streams worth notice, besides the Shannon, on the western boundary, and the Barrow, which for a small distance separates this from Queen's County, are the two rivulets, Brosna, which fall into the former. The Boyne also touches this district on the north-east. There is only one small lake, Lough Pallas; another, Lough Annagh, is partly in Queen's County. The canal from Dublin to the Shannon passes through the county from east to west, along its whole length. The minerals and fossils, hitherto discovered, are iron ores in small quantity, manganesc, ochre, marl, chalk, and potter's clay, with sandstone, limestone, and limestone gravel, already mentioned. Mineral waters occur in several places.

King's County is divided into large estates, and many of their owners do not reside; but much of the land is held on leases, in perpetuity, and the

County.

Farms.

holders of these form a respectable class. The principal proprietors are Lords Digby, Ross, and Charleville. Farms were formerly very large, not unfrequently of the extent of 2000 acres, but their size has been diminished, and such as are considered large do not now exceed, on an average, 400 English acres. Many are as small as twenty acres, though the medium size of the smaller class may be double this. Most of the arable land is tolerably inclosed, chiefly with hedges of whitethorn, which grows here to a great size. Partnership leases and subtenancy are less common than in some other parts of Ireland. Yet the condition of the tenantry and the peasantry does not seem to be materially more improved. The farm buildings of every description are generally very bad, the cottages in particular; and yet those who have been long accustomed to these miserable cabins, are said to prefer them to more comfortable dwellings, which, after having been erected by some of the proprietors, were for some time allowed to stand unoccupied. In other respects, also, there is little difference to remark between the condition of the lower classes in this and the Irish counties before described. The English language is pretty general; the peasants speak both that and the Irish with almost equal facility.

Wheat, barley, and potatoes, are the most common crops. Reducing the Irish acre and corn measures to bush, the average produce of wheat is stated in the *Agricultural Report* to be no more than sixteen bushels of barley and oats, it is about thirty-two bushels of potatoes, only four tons per acre. Both oxen and horses are employed in labour, the plough sometimes drawn by only two or either of a few stances by two heifers. Yet thus and their other implements are not generally of good construction. The thrashing machine has been used in this district for about twenty years. Limestone gravel is much used as a manure, with the best effects, both on tillage and grass lands.

The leases were formerly for thirty-one years or three lives, but the more common period of late is twenty-one years, to which the life of the tenant in possession at the end of it is frequently added. Some tenants hold for lives renewable for ever, paying a renewal fine equal to half a year's rent or more on the fall of every life. Modern leases often contain a prohibition against alienating. Nothing is so much complained of amongst the tenantry as the mode in which tithes are collected. "I really apprehend," says Sir Charles Coote, the author of the *Agricultural Report* for the county, "it would be a very difficult matter to mislead the lower orders of the country folk, was there a reasonable modification of tithe; and they seem one and all discontented, not so much with the institution, as the severe mode of collecting the tax, which is here unusually oppressive." The incumbent, Sir Charles thinks, is not to blame; but he lets the tithe to a proctor, and the proctor relets, or transfers his lease to another and so on, till the person who at last collects the tithe, and necessarily pays a heavy rack-rent, has every inducement to exact it with the utmost rigour.

There is no manufacture carried on here to any

considerable extent. That of linen is the most general, yet not upon a large scale. There are breweries and distilleries at which the greater part of the oats and barley grown in the county are consumed, little of either being used in the food of the lower classes. Coarse woollens are made for their own clothing, as in other parts of Ireland.

The market and post-towns are Banagher, Philips-town, the county town, Balliboy, Birr or Parsons-town, Tullamore, Edenderry, Shinrone, and Clara. Philipstown and Banagher returned two members each to the Irish Parliament, but none of the towns are represented in the Parliament of the United Kingdom. The only members are two for the county. According to Wakefield, the Catholics are to the Protestants as eight to one. In 1801, the population was estimated at 76,000; it is said to be now about 130,000.

See Sir Charles Coote's *Agricultural Survey*, 1801; and the *Works of Young*, Beaufort, New-enham, Wakefield, and the *Statistical Account of Ireland*, formerly referred to under the Irish counties.

(A.)

KINROSS-SHIRE, a county in Scotland, bound-situationed on the north-east, east, and south, by the county of Fife, and on the north and west by Perthshire, is about twelve miles in length from east to west, and ten miles in breadth from south to north, but according to the latest survey, contains only 78 square miles, or 110,920 English acres, being one of the smallest counties in Scotland. Kinross, the county town, situated nearly in the centre, is in north latitude 56 15', and west longitude from Greenwich 1 10'.

Kinross-shire is the highest level ground in the peninsula, formed by the Forth and the Tay, which was formerly called Ross, or the promontory, and included the counties of Fife, Kinross, and Clackmannan. From this county the waters flow in every direction. The soil is in general dry, meaning to gravel, with considerable fields of moss, and some clay and loam. The productive land may extend to 30,000 acres, or about three-fifths of the whole. It contains several lakes, of which Lochleven, in the vicinity of Kinross, is the most considerable. This lake, which is about fifteen miles in circumference, and covers an area of 3,300 acres, contains several islands, which abound in trout, eels, pikes, perch, and flounders. The castle of Lochleven, in which Queen Mary was confined, stands on one of these islands, about two acres in extent. Several rivulets flow into this lake, of which the principal are the Gairny, the South Queich, and the North Queich; and the River Leven, the only stream of any note in the district, issues from its eastern extremity, and, after passing through a considerable part of the county of Fife, enters the Frith of Forth at the town of Leven. The prevailing rocks are whinstone, sandstone, and limestone. Coal has been found on the estate of Blair Adam; it is wrought at Keltie, in the parish of Cleish, on the southern boundary of the county.

Kinross-shire is divided into a number of small estates. Only about ten proprietors hold of the Crown; the others hold of these freeholders, the lands having been let out to them, for the most part

about the end of the seventeenth and beginning of the eighteenth century, for payment of a feu-duty. Hence, over the greater part of the county, every single farm is a separate property, possessed for the most part by its owner. The valued rent is £20,250, 1s. 3d. Scots; and the real rent, according to the *Agricultural Survey*, published in 1814, is £14,541, 10s. Sterling. In 1811, the number of freeholders was only fifteen. When the land is let out to tenants, the leases are from fourteen to twenty-one years, except in the neighbourhood of the villages, where they are for a shorter period; and the rent is paid partly in money, and partly in grain, or according to the price of grain. The size of the farms is from 100 to 300 acres. A great proportion of them is always in grass, for which both the soil and climate are favourable; and much of the land is inclosed either with stone-walls or hedges. The principal corn crops are oats and barley, or big; wheat, though partially cultivated, does not enter into the regular course of cropping. Potatoes, turnips, and clovers, with rye-grass, are raised in every part of the county. On the banks of the Gairny and the Leven, there are meadows of considerable extent, which yield abundant crops of hay. The pastures of the cultivated land are occupied by cattle; sheep are kept in numbers only on the Cleish hills, and on that part of the Ochills which belong to this county. Not much of the district is under wood. The most considerable plantations are on Blair-Adam, the estate

of the Lord Chief Commissioner Adam, and they are in a very flourishing state.

The only villages in this county are Kinross and Milnaboth, the former containing, in 1811, a population of about 1500, and the latter 900. At both these places several fairs are held in the year, but there is no weekly market. Nothing that deserves the name of manufactures is to be found here, except that a few weavers are employed by the manufacturers of Glasgow. Assessments are resorted to for the poor of the villages; but those of the country parishes are relieved by voluntary contributions.

Kinross-shire sends a member to Parliament alternately with the county of Clackmannan. Both counties are under the jurisdiction of one sheriff, who has a substitute for each. There are only four entire parishes, viz. Cleish, Orwell, Kinross, and Portnoak, with portions of other three; the first three belong to the Presbytery of Dunfermline, and the fourth to that of Kirkcaldy, both under the jurisdiction of the Synod of Fife. The population in 1800 and 1811 is given in the annexed abstract. By the returns for the last of these years, there are about 93 inhabitants to the square mile.

See *Beauties of Scotland*, Vol. IV.; *General Report of Scotland*, Vol. I.; *Playfair's Geographical and Statistical Account of Scotland*, Vol. I.; *Dr Graham's General View of the Agriculture of Kinross and Clackmannan*; and, for its antiquities, *Sibbald's History of Fife and Kinross*. (A.)

Situation.

KIRKCUDBRIGHT, a county in Scotland, situated between $54^{\circ} 43'$ and $55^{\circ} 19'$ north latitude, and $3^{\circ} 33'$ and $4^{\circ} 34'$ west longitude from Greenwich, is bounded on the north by the shires of Dumfries and Ayr; on the east and south by the Solway Frith and the Irish Sea; and on the west by the county of Wigtown. It is in length from east to west about 48 miles, varying in breadth from 30 to 17 miles, and contains $882\frac{1}{2}$ square miles, or 564,480 English

Extent

acres. This district is commonly called the *Stewartry*, not the shire, of Kirkcudbright, and its judge, whose powers and duties are the same as those of a sheriff, is called *Steward*. The appellation of stewardry had its rise in the ancient tenure by which it was held, and the subsequent forfeiture of its lords; but the distinction between stewardry and sheriffdom is in this case purely nominal. Kirkcudbright is one of the two counties comprehended under the general

Kirkcud-
bright.

Surface.

name of Galloway; Wigtonshire on the west being the other.

About two-thirds of the surface is mountainous. A range of mountains stretches along the whole northern boundary in the form of a vast amphitheatre, embracing nearly half the county; on the boundary with Ayrshire they are not much inferior in height to any in the south of Scotland. There are also some considerable mountains on the southern extremity, such as Criffel, 1831 feet high; Cairnsmuir, 2597; and Cairnharrow, 1110. The high lands are for the most part covered with heath, except on a part of the northern boundary, where a narrow tract of green hills run out between the shires of Ayr and Dumfries; and many of them are wet and mossy. In the middle of the district, the declivity is so gentle, that the river Dee, at thirty miles from its mouth, is only 150 feet above the level of the sea; yet, even in the interior, there is no great extent of level ground, the greater part of the surface being occupied by rocky knolls, steep banks, and hills of a moderate elevation. On the coast, also, hills rise almost everywhere, to the height of several hundred feet. The district is studded with a great number of lakes, of which there is one or more in almost every parish, though few of them are considerable. As there is little full grown wood, and the plantations are but partial, and for the most part of not many years' growth, the general appearance of the stewartry is that of a bleak exposed country, on which labour has been but recently employed, and where its efforts must always be confined to a comparatively small field. Yet it contains many spots of great natural beauty, particularly on the coast, where the sea in several places has formed deep bays, surrounded with high grounds, some of which are fringed with coppice.

The soil of the lower grounds is, for the most part, of a hazel colour, sometimes inclining to red, and seems to be chiefly composed of argillaceous schistus in a state of decomposition. It is seldom of any great depth, and the rock, often rising above the surface, gives a rugged and sterile appearance to much even of the arable land. This soil is, however, in many instances possessed of great natural fertility, not soon injured by wet seasons, and affords plentiful crops and fine natural herbage. Clay is of no great extent, and found chiefly on the banks of the rivers. The smooth round hills accessible to the plough have, for the most part, a close subsoil, here called *till*, and do not, therefore, admit of being profitably cultivated but after an interval of several years' pasturage. Tracts of moss, commonly from four to eight feet deep, extend over a tenth or twelfth part of the whole county.

Mineralogy.

Much of the mountainous district is composed of granite. According to the *Agricultural Survey*, there are three several districts of this rock, which occupy nearly a fourth of the surface. Strata of very dissimilar substances, to which Dr Hutton has given the general name of schistus, prevail in the lower parts. Some are of a hard compact grain, of a blue or greyish brown colour, for the most part breaking irregularly, but often in parallel plates, of which coarse slates have been made. With these are in-

termixed layers of a soft argillaceous stone, which readily yields to the weather, and is popularly known by the name of *slate band*. These rocks, which also occupy a large part of the district, are sometimes traversed by dikes of porphyry, and also by granite. In the neighbourhood of Dumfries, the prevailing rock is sandstone. Limestone is found at Kirkbeam, on the Nith, the only place in the county where it is wrought; and there are also promising indications of coal on the estate of Arbigland, near Dumfries. In the parish of Colvend, on the Solway Frith, there is a quarry which affords millstones. Lead mines were wrought in Mianigaff, on the western boundary, for many years, but have been discontinued. Iron ore abounds, but, from the want of coal and wood, is of little value. On the estate of Mr Murray of Broughton, near Gatehouse, copper has been lately discovered, and is now working by an English company.

Kirkcud-
bright.

The rivers are the Nith, which separates this county from Dumfries-shire, for about nine miles on the north-east; the Urr, which flows south-east by the village of Dalbeaty, and is navigable five or six miles for small vessels; the Dee, the largest river, which enters Loch Ken, a lake almost in the centre of the county, about eight miles long, and in some places a mile in breadth, and giving its name to the river which issues from the lake, falls into the Solway Frith about five miles below the town of Kirkcudbright. It is navigable for two miles above this town for vessels of 200 tons. In spring tides the water rises about 30 feet at Kirkcudbright, where there is a well-sheltered natural harbour, of easy access. For the last seven or eight miles of its course the banks of the Dee are planted. St Mary's Isle, near Kirkcudbright, is a highly ornamented spot, and the Little Ross, a beautiful island, is situated at its mouth. The salmon fishery on this river was rented, some years ago, at L.900. The Fleet is remarkable for the picturesque scenery on its banks, and is navigable for small vessels to the village of Gatehouse, four miles from the sea. The Cree, a more considerable river, separates this county from Wigtonshire, and flows into the bay of Wigton, from whence it is navigable to the small harbour of Carty, a little below Newton-Stewart. The stewartry is everywhere supplied with pure springs and rivulets. Chalybeate springs are also numerous, one of which, Lochenbreck, in the parish of Balmaghie, seven miles from Gatehouse, is said not to be inferior in medicinal virtues to any in the kingdom.

The landed property is not divided into large estates. Out of 1043, their number in 1808, as given in the *Agricultural Survey*, 972 are stated to have been below L.500 a year. The valued rent, which was taken in 1642, is L.114,637, 2s. Scots; the real rent, in 1808, was estimated at L.167,125 Sterling; and in 1813 at upwards of L.200,000. Many of the smaller proprietors cultivate their own estates. According to the work just referred to, almost half the county is held under deeds of entail, many of which had been executed very lately. "The condition of the peasantry, at a period not very remote, seems to have been much depressed, and the state of husbandry rude and barbarous in

Tenantry.

Kirkcudbright.

the extreme." (Smith's *Survey*.) And in both these respects the stewartry is still behind most of the other southern counties of Scotland. Yet it was here that the improvements of modern husbandry were adopted, at a time when they were entirely unknown in the greater part of the kingdom. So early as 1750 Mr Craik of Arbigland practised the drilling and horse-hoeing of the celebrated Tull, which he ever afterwards continued to follow in the culture of beans and turnips. He inclosed and drained his estate, cleaned his fields by fallowing, applied calcareous manures, introduced sown grasses into his course of crops, and worked his plough with two horses. A few of the other proprietors followed in his steps, but their efforts were not seconded by the tenantry at large. It is only since the end of last century that modern husbandry has made any considerable progress, and it is far from being yet general. A regular alternation of what are called white and green crops is not always observed, and turnips are not so extensively cultivated as potatoes, though the latter must always be a very unprofitable crop in a thinly peopled district. The chief crops are oats and barley, with wheat on the better soils. Unlike other hilly tracts in Scotland, the land is almost universally inclosed, chiefly with stone walls, called *Galloway Dikes*. These dikes are built close, or double, as it is called, for part of their height, and afterwards single, the stones in the latter part being laid in such a manner as to allow the passage of the light through the wall. But it is now becoming a common practice to build the whole of the wall double, and, after laying a course of stones that project a little beyond its breadth on both sides, it is completed by a coping of stones laid on edge and closely pinned.

Galloway Dikes.

Cattle, &c

This county is chiefly celebrated for its cattle, which form by far the most important part of its agricultural produce. They are known in every part of Britain by the name of *Galloway cattle*. (See AGRICULTURE in this *Supplement*.) Sheep are confined to the mountainous districts, where they are kept in great numbers. They are of the heath or black-faced variety, with coarse wool, and yield a very small return for the extent of their pastures, which, however, are in general of the very worst description in the south of Scotland, some large tracts being rented so low as 6d. an acre, or even lower. It has not yet become the practice to combine the rearing and fattening of sheep with the culture of arable land, by which the light soils of the other border counties have been rendered so productive. A small, hardy, and active race of horses, called *Galloways*, was formerly reared here and in Wigtonshire, the other division of Galloway, but a larger breed being required for the labours of modern husbandry, especially since two horse ploughs have become general, the old race is very rarely to be found in a pure state. The name, however, is frequently applied to horses below full size, wherever they are reared.

Roads.

The first road act for the stewartry of Kirkcudbright was obtained in 1779. At that period there was scarcely any thing that deserved the name of a road, except the military road from Dumfries to

Kirkcudbright.

Portpatrick, which had been made about fifteen years before; but at present very few districts are better provided in this respect. The first good roads were made on the estate of the Earl of Selkirk, under the direction of his son Basil William, Lord Daer, to whom this county owes many other improvements. In 1796, by another act of Parliament, the assessments were allowed to be increased and tolls erected, and soon after a new road was made from Dumfries to Castle-Douglas, a distance of nineteen miles, through a hilly broken country, with so much attention to preserve the level, that it has seldom a rise of more than one foot in forty, and much of it is nearly a perfect level. All the principal roads made since have been done with equal judgment. The district is also well accommodated with bridges, of which the most considerable is one over the Dee at Tongland, about two miles above Kirkcudbright, which has an arch of one hundred and ten feet span. It is built of sandstone, brought partly from Annan in Dumfries-shire, and partly from the Isle of Arran, was finished in 1808, and cost upwards of £7000.

Manufactures have made little progress here. Those of soap and leather do not supply the wants of the inhabitants; paper is made at two small mills; and there are four cotton mills at Gatehouse, which have long ago ceased to be in full employment. In some of the towns and villages, a considerable number of weavers are employed by the manufacturers of Glasgow and Carlisle. Its commerce is confined to the export of cattle, sheep, wool, and grain, and the import of lime, coals, groceries, and manufactured goods, with wood from America, and occasionally wood and iron from the Baltic.

Kirkcudbright, the county town, and a royal burgh, contained, in 1811, a population of 2760. It is pleasantly situated on the Dee, and is noted for the information and urbanity of its inhabitants. Societies have been formed here for a purpose rather unusual, namely, the building of houses, not for sale, but for the use of the members who compose them. Every member makes a small monthly payment into a general fund, which is employed in erecting the houses, and these, as they are finished, are assigned to the members by lot, those to whom they fall paying 5 per cent. on the money which their houses have cost, in addition to their monthly payments; and this arrangement continues till all the members be supplied, and the societies dissolved. New Galloway, also a royal burgh, is situated at the head of Loch Ken, and contains only about 650 inhabitants. The principal villages are Cree-town, at the mouth of the river Cree, on the bay of Wigtown; Gatehouse, twelve miles east from the former, on the river Fleet; and Castle-Douglas, formerly called Carlinwark, an inland place, about nine miles north-east of Kirkcudbright. The Galloway Bank was established at Castle-Douglas in June 1806. These three villages seem to be in a thriving state; the houses are for the most part of two stories, and, in other respects, they are superior to villages of the same extent in many other parts of Scotland. The others are Dalbeaty on the river Urr; Keltonhill, noted for its great cattle fairs

in June and November; and Maxwellton, on the Nith, which, though in this county, belongs by its situation to the town of Dumfries, from which it is separated only by the bridge over that river.

Poor.

There are no regular assessments for the poor in the country parishes, but the ordinary kirk-session funds have been much augmented in some parishes, by charitable donations. Several sums have been also destined by individuals to the support of schools, particularly in the parishes of Borgue, Balmaclellan, and Dalry.

Representa-
tion.

The stewartry sends one member to Parliament, who is chosen by about one hundred and forty freeholders. In the elections for the burghs, Kirkcudbright joins with Dumfries, Sanquhar, Annan, and

Lochmaben; and New Galloway with Stranraer, Wigtown, and Whithorn. It is divided into twenty-eight parishes, of which sixteen belong to the presbytery of Kirkcudbright, and two to that of Wigtown, both in the synod of Galloway, and ten to the presbytery and synod of Dumfries. An abstract of the census of 1800 and 1811 is given in the annexed tables.

KLINOMETER, or CLINOMETER, (from *κλίω*, which denotes inclination, and *μετρον*.) the name of an instrument contrived by the late Lord Webb Seymour, a nobleman who devoted his life to the cultivation of science. This instrument is intended to be used by the geologist for measuring the inclination of stratified rocks, and the azimuth in which that inclination lies.

If a plummet-level be applied to an inclined plane in that position in which the edge or bore of the plummet-level is horizontal, and if the edge of the plummet-level be then turned round ninety degrees in the inclined plane, the angle formed by the plumb-line with the line which is perpendicular to the edge of the plummet-level, is equal to the inclination of the inclined line to the horizon. On the same principle the inclination of a plane to the horizon is measured by the Klinometer.

In the Klinometer, represented at Plate XGIV. Fig. 1, AC is a circular plate, the circumference of which is divided into 360 degrees; it has three short feet on its under surface, one of which is seen at S.

The feet on the under side of the plate are of

wood, which is preferred to metal, as less liable to slip when placed on an inclined surface. The ends of the feet are in a plane parallel to the upper surface of the circular plate. The fibre of the wood is set perpendicular to the plate, to diminish the derangement which may happen by the expansion of the wood from moisture.

The arm CG is moveable round the centre of the circular plate. D is an oval hole through which is moveable the catch of a sliding bolt; this bolt passes on the under side of the circular plate; the catch of the bolt is made flush with the surface of the circular plate. The bolt serves to fix the axis C on the circular plate: when the instrument is to be used, C is the axis round which the arm CG turns. When the three short feet of the circular plate are placed on the inclined surface of a stratified rock, the arm which bears the spirit level EE is moved down to the lowest point of the quadrant DD, and the arm CG is moved round till the bubble stands in the middle of the level; the arm CG and the level are then in the intersection of the inclined stratum with a plane parallel to the horizon: the degree on the
